CITRUS, Citron-tree.— Lemon-tree, and Orange, with all the varieties of each. See CITRUS.

CLIFFORTIA; Ilex leaved Cliffortia. (*Shrubby.*)

CLUTIA; *Alaternoide Clutia.*—Purſlane-leaved Clutia—*Elateria*, or Indian Clutia. (*All ſhrubby.*)

COLUTEA; Shrubby Æthiopian Scarlet Colutea.

CONVOLVULUS.——Ever-green Canary Convolvulus—Silvery Convolvulus. (*Shrubby.*)

CORONILLA.—Valentine Coronilla —— Glaucous Coronilla—Silvery Coronilla.—(*Shrubby.*)

COTYLEDON, *Navel-wort.*—Round-leaved— Long-leaved — Hemeſpherical-leaved. (*Succulent.*)

CRASSULA, *Leſſer Orpine.*—Several ſpecies, ſee CRASSULA. (*Succulent.*)

CRINUM, *Aſphodel Lily.*—African Aſphodel Lily—Broad-leaved. (*Herbaceous.*)

CYCLAMEN.—Perſian Cyclamen —Several varieties. See CYCLAMEN. (*Herbaceous*)

DIGITALIS, *Fox Glove.*—Shrubby Canary Fox Glove.

DIOSMA, *African Spiræa.*—Oppoſite-leaved——Hairy leaved—— Red Dioſma, &c. (*Shrubby.*)

DRACOCEPHALUM.——Canary Dracocephalum, or Balm of Gilead. (*Herbaceous and under-ſhrubby.*)

EBONUS, *Ebony.*—— Ebony of Crete. (*Shrubby.*)

ERYTHRINA, *Coral-tree*—Herbaceous Erythrina.

EUPHORBIA,—moſt of the ſorts. See EUPHORBIA. (*Succulent.*)

GENISTA, *Broom.*——Shrubby Canary Broom.

GERANIUM. All the ſhrubby kinds, and ſome herbaceous See GERANIUM.

GNAPHALIUM.—Oriental Gnaphalium, and varieties—Sweet-ſcented Gnaphalium, &c. (*Underſhrubby.*)

GREWIA.—Occidental Grewia. (*Shrubby.*)

HALLERIA.— African-fly Honey-ſuckle. (*Shrubby.*)

HELIOTROPIUM, *Turn-ſole.*——Shrubby Peruvian Heliotropium.

HERMANIA, Althea-leaved.—— Alder-leaved — Lavender leaved —— Gooſeberry-leaved. (*Shrubby.*)

HYPERICUM, *St. John's Wort.*—Warted-leaved Minorca St. John's Wort—Carolina St. John's Wort——China Monogynous St. John's Wort. (*Shrubby.*)

JASMINUM.—*Jaſmine.*—Catalonian Jaſmine—Azorian Jaſmine—Yellow Indian Jaſmine. (*Shrubby.*)

IBERIS, *Candy-tuft.*——Ever-green Tree-Candy-tuft; and Ever-green Striped-leaved—Ever-flowering Tree-Candy-tuft.

INULA, *Inula.* (*Underſhrubby.*)

JUSTICIA, *Malabar-nut-tree.*

IXIA,—African Woolly-headed *Ixia*—— Bulbiferous *Ixia*—Flexuoſe *Ixia*—Corymboſe Spotted-flowered *Ixia.* (*Herbaceous.*)

KIGGELARIA.—African *Kiggelaria.* (*Underſhrubby.*)

LANTANA, *American Viburnum.*—African *Lantana*, or *Ilex*-leaved Jaſmine—Sage-leaved *Lantanta.* (*Shrubby.*)

LAVATERA.—Cape Lavatera. (*Underſhrubby.*)

LAVENDULA, Lavender.——Cut-leaved Canary-Lavender. (*Underſhrubby.*)

LAURUS, *Bay-tree.*—Carolina Blue-berried Bay—Red-berried Bay-tree—Indian Bay-tree—Cinnamon-tree—Camphire-tree—Deciduous Bay-tree.

LEONURUS, *Lion's-tail.*—African Scarlet Leonurus—Striped-leaved Leonurus. (*Herbaceous.*)

LOBELIA.——Shrubby, Pine-leaved, Blue Lobelia.

LOTUS, *Bird's-foot Trefoil.*—Cretan Silvery Lotus—*Lotus Jacobæus*—Upright Lotus—Proſtrate Lotus. (*Underſhrubby and herbaceous.*)

LYCIUM, *Box-thorn.*—African Box-thorn—Barbary Box-thorn. (*Shrubby.*)

MALVA, *Mallow.*—African Shrub Mallow.

MEDIOLA.—Climbing African Mediola. (*Underſhrubby.*)

MEDICAGO.—Shrubby Hoary Medicago, or Moon Trefoil.

MELIA.—Bead tree.

MENTHA, *Mint.*—Tree-Mint.

MESEMBRYANTHEMUM, *Fig-Marigold*—Many curious ſpecies. See MESEMBRYANTHEMUM. (*Succulent.*)

MOREA.—Canaliculated-leaved Morea—Ruſh-leaved Morea.

MYRICA, *Gale, Sweet Willow*, or *Candleberry Myrtle.*—Oak-leaved Myrica—Æthiopian Heart-leaved Myrica. (*Shrubby.*)

MYRTUS, *Myrtle-tree.*—Common Myrtle; there being but one ſpecies, which comprehend many eminent varieties. See MYRTUS. (*Shrubby.*)

NERIUM, *Oleander*, or *Roſe-bay.*—Common Oleander—with red flowers—ſcarlet flowers—white flowers—double flowers—ſtriped-leaved. (*Shrubby.*)

OLEA, *Olive-tree.*—European Olive-tree—Cape, or African Olive-tree.

ONONIS, *Reſt Harrow.*—Shrubby Spaniſh *Ononis.*

ORIGANUM, *Origany.*—Dittany of Crete. Dittany of Mount Sipylus—Cretan Marjoram—Origany of Smyrna. (*Underſhrubby.*)

ORNITHOGALUM, *Star of Bethlehem.*—Cape Onithogalum. (*Herbaceous.*)

OSTEOSPERMUM.—Hard-ſeeded Chryſanthemum. (*Shrubby.*)

OTHONNA, *Ragwort.*—Pectinated, or Wing-leaved Othonna—Southernwood-leaved. (*Shrubby.*)

PASSERINA, *Sparrow-wort.*—Shrubby African Paſſerina.

PERIPLOCA, *Virginian Silk.*——African hoary climbing Periploca, and varieties. (*Underſhrubby.*)

PHLOMIS, Jeruſalem Sage.—Yellow Phlomis, and varieties—Purple Phlomis. (*Shrubby.*)

PHYLICA, *Baſtard Alaternus.*—Box-leaved Phylica—Heath-leaved. (*Underſhrubby.*)

PHYLLIS, *Baſtard Hare's-ear*, or *Simpla Nobla.* (*Underſhrubby.*)

PHYSALIS, Alkekengi, or Winter Cherry—Somniferous Winter Cherry—Flexuoſe Winter Cherry. (*Shrubby.*)

PISTACIA, *Piſtachia nut*, and *Maſtic-tree*, two or three varieties. (*Shrubby.*)

POLYGALA, *Milk-wort.*—Shrubby Myrtle-leaved Polygala.

PORTULACA, *Purſlane.*—Shrubby Cape Purſlane-tree.

POTERIUM, *Burnet.*——Shrubby Prickly Burnet.

PRASIUM, *Shrubby Hedge Nettle.*

PROTEA, *Silver-tree.*—Common Silvery *Protea*, or Changing-tree—Coniferous *Protea.* (*Shrubby.*)

PUNICA, *Pomegranate-tree.*—Dwarf Pomgranate.

RHAMNUS, *Buck-thorn.*——Broad-leaved Indian *Rhamnus*—Zizyphus, or Jojube. (*Underſhrubby.*)

RHUS, *Sumach.*—African Hoary Sumach, and varieties—African Narrow-leaved Sumach, and varieties—Shining-leaved African Sumach. (*Shrubby.*)

ROYENA, African Bladder-nut. (*Shrubby.*)

RUMEX, *Dock.*—Sorrel-tree.

RUSCUS, *Knee-holly.*—Alexandrian Laurel—Tongue-upon-tongue Laurel: they will alſo grow in the full air, but are liable to injury from froſt. (*Shrubby.*)

SALVIA, *Sage.*—Shrubby African Golden-flowered Sage—Shrubby African Blue-flowered Sage—Canary Sage—Mexican Sage. (*Shrubby.*)

SCABIOSA, *Scabious.*—Shrubby Scabious.

SCLARIA, *Clary.*—Shrubby Mexican Clary.

SELAGO.—Corymboſe Selago. (*Underſhrubby.*)

SEMPERVIVUM, *Live-ever*, or *Houſe-leek*. Tree Houſe-leek—Variegated Tree Houſe-leek—Leſſer Canary-tree Houſe-leek. (*Succulent.*)

SENECIO, *Groundſel*. — Shrubby African Groundſels.

SIDERITIS, *Iron-wort*.—Canary Iron-wort—Cretan Iron-wort. (*Shrubby.*)

SMILAX, *Rough Bindweed*. —— Chineſe Rough Bindweed, or China-root—Laurel-leaved Rough Bindweed; with ſeveral varieties of each. (*Underſhrubby.*)

SOLANUM, *Night-ſhade*.—*Amomum Plinii*, Baſtard Capſicum, or Winter Cherry—African Jagged-leaved Solanum, or *Pomum Amoris*—American Twin-fruited Solanum—Thorny, Downy Night-ſhade. (*Shrubby and herbaceous.*)

STOEBE.—Baſtard Elichryſum. (*Underſhrubby.*)

TANACETUM, *Tanſey*.—Shrubby Æthiopian Tanſey—Underſhrubby Samphire-leaved Tanſey—Tree Tanſey.

TARCHONANTHUS.——Shrubby African Flea-bane.

TETRAGONIA.—Shrubby *Tetragonia*.

TEUCRIUM, *Germander*.—Spaniſh Tree-Germander—Broad-leaved Tree-Germander—*Polium*, or Mountain Poly.—*Murum*, or Syrian Maſtich. (*Shrubby and Underſhrubby.*)

TROPÆOLUM, *Indian Creſs*.—Double Indian Creſs, or *Naſturtium*. (*Herbaceous.*)

VITEX, *Chaſte-tree*.—Ever-green Chaſte-tree.

ULEX, *Furze*, or *Whins*.—African Berry-bearing Furze. (*Shrubby.*)

XANTHOXYLUM.—Tooth-ach-tree.

XERANTHEMUM.—Broad-leaved *Xeranthemum*—Narrow-leaved *Xeranthemum*—Trailing *Xeranthemum*. (*Shrubby.*)

YUCCA, *Adam's Needle*.——Common Adam's Needle——Thready-leaved Adam's Needle—Aloe-leaved *Yucca*—Dragon tree-leaved Yucca. (*Shrubby ſtemed and ſucculent.*)

ZYGOPHYLUM, *Bean Caper*.——Seſſile-leaved Bean Caper—Purſlane-leaved Bean Caper. (*Shrubby.*)

With reſpect to the general culture of the above liſt of Green-houſe exotics, they muſt be kept conſtantly in pots or tubs, for moving them into ſhelter in winter, and into the open air in ſummer; for being all exotics from the warm parts of the world are of tender quality here, and conſequently not able to live in the open air in the winter, therefore requiring the protection of the Green-houſe during that ſeaſon, are denominated Green-houſe plants.

Moſt of them will proſper in any good rich earth of a garden; ſome ſorts, however, require a particular compoſt, which will be always exhibited under each particular article; and moſt of the ſucculent tribe, as being replete with moiſture, ſhould always be planted in a dry, poor, lean, rubbiſhy ſoil. See COMPOSTS.

As to the pots and tubs to contain the plants, they muſt be of different ſizes, according to the ſize and nature of the plants; which as they advance in growth, ſhould have larger pots, &c. accordingly; and when they become too large for the pots, they muſt be ſhifted into tubs, hooped with iron, with two iron handles to each at top. See POTS and TUBS.

In planting the different ſorts, be careful that the pots or tubs have holes at bottom for the diſcharge of redundant moiſture; obſerving, however, previous to putting in the earth, to cover each hole with a piece of tyle or oyſter-ſhell, to prevent their being ſtopped up with the earth, and the earth from being waſhed out, &c.

As to the mode of propagating the various ſorts, it is in ſome by ſeed, others by layers, cuttings, ſlips, off-ſets of the roots, &c. and ſome by grafting, inoculation, and inarching; all of which is illuſtrated under their ſeveral genera.

And as to the mode and times of planting each ſort, it is alſo fully explained under their ſeveral genera as they occur in the courſe of this work.

Therefore, ſuppoſing all the ſorts to be now raiſed, and planted in their proper pots, ſoils, &c. we will juſt give ſome hints for their general management.

*Removing them into the Open Air in the Summer, and Management there.*

All the ſorts ſucceed in the open air from May, or beginning of June, until October; and from October until May or June again, as juſt obſerved, require the ſhelter of the Green-houſe: therefore, about the middle of May is the time to remove the more hardy kinds of Green-houſe plants, in their pots, into the full air, ſuch as all the varieties of Myrtles, Geraniums, Oleanders, Ciſtuſes, Phlomiſes, Shrubby Aſter, Tree-wormwood,

Tree-

Tree-Candy-tuft, Yellow Indian and Spaniſh Jaſmines, Indian Bay, &c. and in the laſt week in May or firſt in June, according as the ſeaſon proves more or leſs favourable, bring forth all the other ſorts; but this ſhould not be done until the ſeaſon is become perfectly ſettled, and a fair proſpect of ſummer being arrived, for we have often very cold nights, and frequently froſty mornings, in May, and even in the beginning of June, which, if the plants were fully expoſed, would pinch the ends of their young ſhoots and leaves, and greatly deface them. It is a good obſervation, that when the mulberry-tree, which is a late ſhooter, begins to expand its leaves, is a certain ſign of the approach of ſummer, and ſettled weather, fit to begin moving out moſt ſorts of Green-houſe exotics. A mild warm day ſhould be choſen for this work, and if a warm rain it will be of much advantage, as it will waſh the leaves and branches from the duſt they have contracted, and greatly refreſh the plants.

When they are firſt brought out, it is proper to place them in ſome ſheltered ſunny place, for a fortnight, till they are inured to the open air; then you may place them in any open expoſure where you deſign they ſhall remain for the ſummer.

As ſoon as they are brought out, let them be cleared from all dead leaves, and all dead wood; and let the earth on the ſurface of the pots be ſtirred, taking a little of the old out, and add ſome freſh mold in its ſtead, which will prove very beneficial; then give a moderate watering, not only to the mold, but alſo all over the heads of the plants, to clean them effectually from all dirt and filth they may have contracted during their reſidence in the Green-houſe.

As to the diſpoſition of thoſe plants in the full air, no general rule can be exhibited, it is according to fancy. Sometimes ſome of the handſomeſt plants are placed to adorn ſpacious fore-courts, and ſometimes are arranged on each ſides of grand walks contiguous to the main habitation, and others near ornamental garden-buildings; they are alſo ſometimes diſpoſed in groups or ſmall clumps in the moſt conſpicuous places, in different parts of the pleaſure-ground; exhibiting different ſorts in each group, to cauſe the greater variety.

Having, however, placed the whole abroad for the ſummer, their chief culture is, to ſupply them plentifully with water during that ſeaſon, in hot dry weather: all the woody or ſhrubby kinds in particular, likewiſe the herbaceous kinds that are not very ſucculent, will require it three times a week at leaſt, and in a very hot dry time once a day will be requiſite; the ſucculent kinds muſt alſo have a moderate ſupply of water two or three times a week in dry weather; obſerving that the proper time of the day for watering all the ſorts at this ſeaſon, is, either in a morning before nine o'clock, or in the afternoon after four or five; for if performed in the middle of the day in ſummer weather, the ſun would ſoon exhale great part of the moiſture before it effected its intended operation on the fibres of the plants: this work of watering ſhould be duly attended to in dry weather, for as the mold, roots, and fibres of the plants are circumſcribed within the narrow limits of a pot or tub, the earth contained therein, as well as the fibres, conſequently dries very faſt in ſummer, and neceſſarily requires frequent refreſhments of water, to preſerve that due and conſtant degree of moiſture requiſite for the ſupport of vegetation.

It ſhould be obſerved, that moderate rains ſhould not deter you from watering, eſpecially ſuch plants that have ſpreading heads, which prevents the rains, unleſs very heavy or conſtant, from falling in ſufficient quantities on the earth of the pots, to moiſten it properly.

In hot weather, if ſome mowings of ſhort graſs are ſpread on the ſurface of the orange-tree tubs, and others, it will greatly preſerve the moiſture.

During the ſeaſon it will alſo be good culture to looſen the ſurface of the earth now and then, in ſuch pots and tubs that have a tendency to bind.

*Removing them into the Green-houſe for the Winter, and Management there.*

Towards the latter end of September, or as ſoon as the nights become cold, begin to move into the Green-houſe the more tender kinds of exotics of that department; the ſucculent tribe in particular, ſhould be removed to ſhelter at the firſt approach of exceſſive wet and cold nights. The oranges, lemons, and all the other ſpecies of *citrus*, ſhould alſo be moved into ſhelter in due time, either in the end of September, or early in October, for if they are permitted to remain in the open air till attacked by ſharp weather, it would change the beautiful verdure of their leaves,

leaves, to a ruſty yellow hue, which they would not recover during winter; therefore in October at lateſt, begin to move in the principal plants, the ſucculent and others of the more tender temperature as early in the months as the cold weather begins to come on, and continue moving in all the others as the cold encreaſes, and by the end of the month, or firſt week in November, bring in the whole collection; obſerving according as the time approaches for moving in the different ſorts, to clear them perfectly well from decayed leaves, &c. and let all the pots be well cleaned, and looſen the ſurface of the earth in each pot, adding a little freſh mold thereto, which will prove very beneficial to the plants, as well as add an air of neatneſs and culture. As you bring the different ſorts occaſionally into the Green-houſe, they may be placed promiſcuouſly, till the whole collection is brought in, then ſhould be arranged regular, as they are to remain for the winter; leaving all the windows quite open till that time. When the whole is brought in, or bringing in, let them be diſpoſed in regular order, ſo as to appear to the beſt advantage, both in reſpect to their general arrangement, as well as to exhibit variety, and ſo as each may have an equal portion of ſun and air: let the talleſt plants be therefore arranged in the back, the others in their ſeveral ranks, according to their degrees of height, gradually down to the loweſt in front; and as there is a vaſt variety, both in ſize, ſhape, and colour, of the foliage of the different ſorts, they ſhould be ſo diſpoſed as to ſet off each other, and give a pleaſing variety to the whole; and if poſſible, the plants ſhould ſtand clear of one another; whereby each plant will be ſeparately conſpicuous, and the whole exhibit a greater air of freedom and variety, articles of great elegance, as well as admit an equal portion of ſun and free circulation of air, which will prove beneficial to the health and beauty of the whole collection.

The plants being now all ſtationed in their winter quarters, their principal culture during their reſidence there, is the ſupplying them with freſh air at all opportunities in mild weather, and giving moderate waterings occaſionally, picking off decayed leaves as often as they appear, and making occaſional moderate fires in ſevere weather, alſo ſometimes to diſpel great damps and noxious fogs.

With reſpect to giving air, this ſhould be admitted every mild, calm day, by opening the windows more or leſs, according to the temperature of the weather. When the plants are firſt houſed, they ſhould have as much free air as the nature of the ſeaſon will admit, by opening the windows every mild day to their full extent; and if the air is quite temperate, they may remain open on nights for the firſt week; but in cold nights, let them be conſtantly ſhut: this work of admitting air muſt be conſtantly attended to all winter, for without a due portion of this eſſential article in mild weather, the plants would looſe their fine verdure, and aſſume a ſickly yelloviſh colour, become diſeaſed, and the young ſhoots grow mouldy and rot off, and the leaves of the plants drop; therefore, never omit every mild day, when not very damp or ſoggy, to open ſome or all of the windows, little or much, according as the air is, more or leſs temperate; and the proper time of day during winter, for this is from about eight, nine, or ten in a morning, till three, four, or five in the evening, according to the mildneſs of the day: but as the days lengthen, and the warm weather encreaſing, give more air in proportion, earlier and later in the day as you ſhall judge proper, being careful always to ſhut all cloſe in due time every evening, as ſoon as the ſharp air approaches. In foggy weather it is adviſeable to keep the windows quite cloſe, for the great damps occaſioned by fogs is very pernicious to theſe plants, whilſt they are confined in the houſe; likewiſe in all froſty weather keep the houſe all cloſe, except the froſt is moderate, and the middle of the day ſunny and warm, when ſome of the windows may be opened a little, but ſhut them cloſe again if the ſun is clouded, and at any rate before the air changes cold; and in ſevere weather, let the ſhutters, &c. be alſo ſhut every night, alſo occaſionally on days. As the ſpring approaches, and the weather grows warmer, enlarge the portion of air accordingly, admitting it alſo, both earlier in a morning, and continue it longer in the evening, as the days lengthen, for then the plants will begin to aſſume a growing ſtate, and a conſiderable portion of air is requiſite every mild day, both to ſtrengthen the new ſhoots and inure the plants by degrees to the air, againſt the time for removing them into it fully again for the ſummer.

Watering during their abode in the Green-houſe will alſo be neceſſary to moſt of the ſorts, but which muſt be afforded them as ſparingly as poſſible during the winter months, and ſcarcely any ſhould be given when the houſe

houſe is obliged to be ſhut cloſe through the ſeverity of the weather: there are no certain rules to be given for the application of this article, ſome plants may probably require a little water once a week, or ten, or twelve days in mild weather, ſuch as the orange and lemon-trees, myrtles, oleanders, ſhrubby-geraniums, and other woody kinds; all that is neceſſary is, juſt to preſerve the earth very moderately moiſt; therefore muſt examine the pots and tubs always with proper attention, and give water to ſuch only as you ſee are in want thereof, not to make it a rule to give it whether they want it or no. The herbaceous kinds ſhould be rather more ſparingly watered than the ſhrubby ſorts; and all the ſucculent tribe ſhould have water but ſeldom, ſome not oftener than once a fortnight or three weeks, and that always but very ſparingly at each time; and ſome that are very ſucculent will require but very little from November till March; and indeed all the ſucculents ſhould only have it now and then at this ſeaſon, when the earth in the pots appears very dry.

In performing the work of watering in general, be particularly careful to water with great moderation whilſt the plants remain in the Green-houſe, for if you once over-wet the earth at this ſeaſon, it will remain ſo for a long time, and by chilling the tender fibres of the roots, the conſequence will often prove the loſs of the leaves of many of the plants, and even the death of ſome ſorts.

A ſunny day from about eleven to two o'clock, is the proper time for watering during their reſidence in the Green-houſe.

Let ſoft water if poſſible be uſed, or at leaſt ſuch that has been expoſed to the air two or three days to ſoften it a little.

In froſty weather great attention is requiſite to keep all the windows cloſe, night and day, unleſs the froſt is but moderate, as before obſerved, and the middle of the day ſunny and warm, when ſome part of the houſe may be opened a little for two or three hours, having particular regard to ſhutting all cloſe in due time in the afternoon, before the air changes ſharply cold: and in very ſevere froſts keep all cloſe night and day, and let the ſhutters, if any, or other covers of canvas or mats, be alſo uſed every night; alſo occaſionally in day time, when the weather is intenſely ſevere, and no ſun appears, and no flues for fires to keep out the froſt; obſerving however the ſhutters or other ſhelters beſides the glaſſes, muſt be uſed as little as poſſible in the day, only in caſes of particular neceſſity as above, for every opportunity ought to be taken for the admiſſion of light and freſh air, as much as the temperature of the weather will poſſibly admit; as moſt of the plants only want protection from froſt, and that the common ſhelter of the houſe, with ſhutting the ſaſhes cloſe every night, will be always ſufficient, except in extremely piercing weather, when the ſhutters, &c. muſt alſo be occaſionally uſed; and if none, nail mats againſt the outſide of all the glaſſes, eſpecially thoſe at top, which form a half roof, if any, for the perpendicular froſts will be more powerful in that part than in the upright glaſſes in front.

During ſevere froſty weather, if your Green-houſe is accommodated with flues for fires, it will be adviſeable to make a moderate fire at ſuch times when the froſt cannot be otherwiſe kept out, eſpecially on nights; but this muſt by no means be continued longer than juſt neceſſary to guard againſt very ſevere froſts. In default of flues, fires are burned within the houſe, in pots placed in different parts: charcoal is often uſed, tho' its ſuffocating vapours in cloſe ſhut houſes, is often attended with danger both to the gardener and plants, ſo that coal, or peat, or turf fires will be better; but there is nothing ſo effectual and eaſy as flues for making fires in ſevere froſts.

Likewiſe in very cold foggy, damp weather, a moderate fire now and then in the flues, will prove very beneficial in expelling the damp unwholeſome vapours, ſo pernicious to all plants.

Whilſt the plants remain in the Green-houſe, all decayed leaves, &c. ſhould be conſtantly picked off, being neceſſary both to preſerve the beauty and health of the plants; decayed leaves of the ſucculent kinds ſhould be cut off cloſe with a ſharp knife; the plants in general ſhould likewiſe be occaſionally cleaned from any filth they may contract in the houſe, ſuch as duſt, cob webs, &c.

The above directions are principally all that are neceſſary during the continuance of the plants in the Green-houſe.

In May and June they are to be removed into the open air again, and managed as before directed in their ſummer culture.

*Some Obſervations on their General Culture.*

The plants in general will want ſhifting occaſionally into larger pots and freſh earth, according

according as they advance in growth; ſome that are faſt growers, ſuch as *geraniums*, *&c.* will require ſhifting annually, others every other year, though an annual ſhifting will prove beneficial to moſt of the ſorts, obſerving, in the work of ſhifting, moſt of them may be ſhifted with the ball of earth about their roots entire, others that are rather weak and ſickly, will require ſhifting into entire freſh earth.

The proper time of year for ſhifting all the ſorts is April and May, or when they are removed into the open air for the ſummer; in doing of this, the plant ſhould be drawn out of its preſent pot or tub with the ball of earth about its roots entire, then pare off all the matted fibres around the outſide of the ball, and clear away alſo ſome of the old earth at ſides, bottom, and top: then having the new pot and freſh earth ready, cover the holes at the bottom of the pots, &c. with pieces of tyles or oyſter-ſhells; and having then put in ſome of the freſh earth, place the plant in the pot and fill up the vacancy all around with more freſh compoſt, bringing it an inch over the top of the ball, and give directly a good watering, to ſettle the earth cloſe in every part; after this it is neceſſary to place the plants to have ſhade from the mid-day ſun for a fortnight.

Such plants that are become of a weak ſickly nature, ſhould, at ſhifting, have all the earth taken clean from about their roots, then waſh the roots, and plant them into entire freſh earth.

The larger ſorts of plants, ſuch as the orange-trees, lemons, citrons, and others of large growth, ſhould, when grown large, be ſhifted from pots into tubs hooped with iron, having two iron handles at top, for the convenience of lifting them in and out of the Green-houſe, for ſometimes they grow to ſo large a ſize, having tubs in proportion, that they require two, and ſometimes three or four men to move them in and out.

Plants of any of the ſorts which are not ſhifted annually, ſhould, in ſpring, have the earth in the top of the pot or tub looſened to a little depth, alſo a little way down round the ſides, taking the looſened earth out, and in its ſtead, add a due quantity of freſh mould, giving it directly a little water to ſettle it cloſe, which will prove a very beneficial dreſſing, and ſhould never be omitted to thoſe that are not ſhifted.

Likewiſe, at any time of the year, when you perceive the ſurface of the earth aſſume a binding property, whether in the ſhifted or unſhifted plants, it is of much ſervice to ſtir it an inch depth occaſionally, and may add a little freſh compoſt, or none at all, as you ſhall judge neceſſary.

Keep all the ſorts conſtantly cleared from the decayed leaves and dead wood, and their heads and every part clean from duſt and other filth, by occaſionally waſhing them with water, which in the hardy ſorts is done by occaſional waterings all over their heads, others when very foul, by waſhing their leaves one and one, with a ſponge and water, eſpecially in winter, and is often neceſſary to the oranges and lemons, and other large-leaſed kinds.

When the heads of any of the ſhrubby plants are become very irregular or ſhabby, the branches may be pruned ſhorter or longer as it ſhall ſeem neceſſary, in April or May, and they will branch out into young wood in ſummer, which you may regulate as occaſion may require.

Never clip the heads of any of the plants with garden ſhears, nor by any mode of pruning, endeavour to trim them into any regular figure, as ſometimes practiſed, but let every ſort aſſume its own natural growth, only juſt uſing the knife to regulate any very irregular or rambling ſhoot or branch, or to thin out ſome where too much crowded, and to cut out all dead wood.

GREWIA, *(Grewia.)*

It conſiſts of two tender ſhrubs for the green-houſe and ſtove, riſing five or ſix feet high, ornamented with oval and ſpear-ſhaped leaves, and pentapetalous flowers.

Claſs and order, *Gynandria Polyandria.*

*Characters.*] CALIX, five ſpear-ſhaped, ſpreading coloured leaves. COROLLA, five ſpear ſhaped petals. STAMINA, many gynandrous filaments, and roundiſh antheræ. PISTILLUM, a roundiſh, germen, filiform ſtyle, and quadrifid ſtigma. PERICARPIUM, a four-lobed, quadrilocular berry, and four globular ſeeds.

The ſpecies are;

[1]GREWIA, *Occidentalis.*

*Occidental Grewia.*] Grewia, with a woody, ſmooth, dark-brown ſtem, branching eight or ten feet high, oval, acute, crenated leaves; and bright purple flowers ſingly from the ſides of the young branches.

[a]GREWIA, *Orientalis.*

*Oriental Grewia.*] Grewia, with a woody brown ſtem branching out laterally five or ſix feet high; oval, ſpear-ſhaped, ſerrated, alternate leaves, and greeniſh flowers in cluſters from the ſides and ends of the branches.

Theſe ſhrubs flower in ſummer, but are not ſucceeded by ripe berries in England.

They are propagated by ſeed, layers, and cuttings; ſow the ſeed in pots, and plunge them in a hot-bed; layers may be performed in ſpring, and they will be rooted by the end of ſummer; and cuttings may be planted in pots alſo in ſpring, plunging them in a hot-bed; they will be rooted in two or three months.

GROVES, plantations of ſtately trees diſpoſed in rows on graſs-ground in gardens, and parks, contiguous to ſpacious lawns, &c. deſigned both for ornament, and to form ſhade from the ſummer's ſun.

In extenſive gardens Groves may be formed in different parts of the ground; a grand one contiguous to the dwelling, where it may be conſpicuous, is proper, both to effect ornament, and that company may ſoon arrive under its ſhade for occaſional walking in the heat of ſummer; others may be ſtationed more remote from the habitation on the boundaries of lawns or other open ſpaces of graſs, and near garden buildings, ſuch as temples and other ſacred ſtructures; for Groves whereſoever ſituated, always exhibit an air of magnificence, and are the greateſt ornaments to ſpacious gardens, and every ſuch garden is incomplete without one or more of theſe plantations.

The trees to form Groves are uſually diſpoſed in ſeveral ſtraight rows, and at ſuch diſtances as their branches may ſo far approach each other, as to afford a moderate ſhade from the ſummer's ſun, yet ſo diſtant, that each tree may have full ſcope to ſpread its branches all around, ſo as to exhibit their ſtraight trunks and ſpreading heads diſtinct, according to their natural growth; that a due portion of air and light may be admitted to promote the growth of the graſs between and under them, ſo as to form a cloſe, firm ſward, and perpetual verdure; Groves are alſo ſometimes formed with the trees placed irregularly, and the ſpaces between planted with various ſhrubs to form under-wood, and with ſerpentine gravel walks variouſly winding through the whole.

But Groves are of two ſorts, open Groves, and cloſe Groves.

*Open Groves.*—The largeſt growing foreſt-trees with the moſt ſpreading heads, ſhould be choſen for ſuch plantations, and diſpoſed in ranges from fifteen to twenty or thirty feet wide, and the ſame diſtance between the trees in each row, that each tree, as above obſerved, may have full ſcope to form a ſpreading head, and ſo as to admit of the growth of graſs under them ſufficiently to form a good ſward, and conſtant verdure; but if a ſhady Grove is required to be formed as ſoon as poſſible, one may be planted contiguous and diſtinct from the above, arranging the rows only at ten or fifteen feet diſtance, whereby it will afford ſhade ſeveral years before the other, and as it will always exhibit a more dark and gloomy ſhade for ſolitude, it will exhibit the greater variety, with the other more open Grove. Open Groves chiefly for ſhade are alſo formed by diſpoſing all the trees irregularly, both that they may produce an imitation of a natural Grove, and ſooner afford a perfect ſhade and gloomineſs, which they will conſiderably ſooner than in ſtraight rows, though Groves deſigned principally for ornament, having the trees diſpoſed in wide ranges, appear generally with a greater air of grandeur as open Groves; but where there is extent of ground to work upon, open Groves may be formed in all the above methods.

*Cloſe Groves.*—Theſe are formed of large trees irregularly diſpoſed, having the ground between them filled with various under ſhrubs and gravel or ſand walks, continued through them in winding or ſerpentine turns; and which kind of Groves are ſometimes continued round the out boundaries of a garden, ſo as to afford ſhady and private walking, as well as ſhelter from the inclemency of cold cutting winds; and the various ſhrubs forming the under-wood will have a delightful effect in the whole excurſion of the walk.

But with reſpect to Groves in general, it ſometimes happens when a garden is to be laid out, that large old trees are found growing upon the ſpot, in a proper ſituation to conſtitute a Grove, which if they do not too greatly approach to the habitation, nor obſtruct any principal proſpect or diſtant view, they ſhould be preſerved with the utmoſt care; and at any rate it will be better to diſpenſe with many inconveniencies, than to deſtroy them, which would require an age or

two to form the like with any young plantation; and that although the trees ſhould ſtand ever ſo irregularly or cloſe, they may be ſomewhat regulated by grubbing up the moſt irregular and ill formed, or thinning out ſome, where they form too cloſe a thicket for the deſign, either for an open or cloſe Grove.

---

# H.

HÆMANTHUS, Blood-flower.

The plants are bulbous-rooted, herbaceous, flowery perennials for the ſtove, having the roots crowned with long leaves, and erect flower-ſtalks a foot high, terminated by cluſters of monopetalous, ſix-parted, liliaceous-ſhaped red flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, a large ſix-leaved, permanent involucrum, ſhaped like an umbel. COROLLA, is one erect petal, divided into ſix parts. STAMINA, ſix awl-ſhaped filaments, and oblong incumbent antheræ. PISTILLUM, a germen under the corolla, ſingle ſtyle, and ſtigma. PERICARPIUM, a roundiſh trilocular-berry, and three ſeeds.

The ſpecies;

[1]HÆMANTHUS, *Coccineus.*

*Scarlet Cape Hæmanthus, or Bloody Lily.*] Hæmanthus with a large, tunicated, bulbous root; crowned by tongue-ſhaped, flat, ſmooth, fleſhy leaves, ſpreading on the ground, and an upright, thick, ſpotted ſtalk, from three to ten or twelve inches high, terminated by a large cluſter of blood-red flowers in autumn.

[2]HÆMANTHUS, *Puniceus.*

*Red Guinea Hæmanthus, or Baſtard Dragon.*] Hæmanthus with a large, bulb-like, fleſhy root, ſending up thick, fleſhy ſtalks a foot high, ſpotted like the dragon-plant, and garniſhed with lanceolate-oval waved, erect leaves, and large umbellate cluſters of red flowers in ſummer.

[3]HÆMANTHUS, *Carinatus.*

*Carinated-leafed Cape Hæmanthus.*] Hæmanthus with a large, bulbous root, crowned by three or four long, narrow, carinated, or keel-ſhaped leaves; an upright, thick ſtalk a foot high, terminated by a cluſter of pale-red flowers in autumn.

[4]HÆMANTHUS, *Ciliaris.*

*Ciliated Cape Hæmanthus.*] Hæmanthus with a large, bulbous root, tongue-ſhaped, ciliated leaves, and an upright, thick ſtalk a foot and half high, terminated by reddiſh flowers in autumn.

All theſe plants are exotics of Africa, and require the protection of a hot-houſe in this country, ſo muſt be always kept in pots, and continued in that department, where if plunged in the bark-bed, they will flower annually, and make a fine appearance.

They are herbaceous, bulbous-rooted perennials, durable in root, but renew their leaves and ſtalks annually, obſerving, that the autumnal flowering kinds generally flower before the leaves ariſe; and when the flower fades, the leaves come up, continue all winter, and decay in ſpring or early in ſummer.

Their flowers are extremely ornamental, appearing in large cluſters, protruded from a large permanent involucrum; each ſeparate flower is of one petal, divided into ſix parts; ſee the *Characters*, and are ſucceeded by red berries, but rarely any but the ſecond ſort ripen in perfection in England.

All the ſorts muſt be potted in light earth, and the proper time for planting, tranſplanting, or to new-pot them is in ſpring, or early in ſummer, when their leaves decay, and the roots may be had of moſt of the nurſery-men, who propagate them for ſale; tho' they encreaſe but ſlowly here, ſo are often procured from the Cape of Good Hope, where they naturally grow, they ſhould be planted as ſoon as they arrive, obſerving to ſupply them with water, which however muſt be but ſparingly in winter.

They may be propagated by off-ſets from

the roots, when their leaves, &c. decay, like bulbs; and may alſo be propagated by ſeeds ſowed in pots of light ſandy earth, plunging them in the bark bed in the ſtove.

HÆMATOXYLUM, Blood-wood, or Log-wood.

It furniſhes one ſpecies, an exotic-tree of South America retained here in ſtoves for variety.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, is five-parted, and permanent. COROLLA, five oval petals. STAMINA, ten long filaments, and ſmall antheræ. PISTILLUM, an oval germen, ſimple ſtyle, and thick indented ſtigma. PERICARPIUM, an unilocular capſule and compreſſed ſeeds.

There is but one ſpecies, viz.

HÆMATOXYLUM, *Campechianum.*

*Campeachy Hæmatoxylum, or Log-wood.*] Hath an irregular, crooked ſtem, riſing fifteen or twenty feet high, ſends out many crooked branches armed with thorns, and garniſhed with pinnated leaves of three or four pair of lobes; and from the axillas erect bunches of pale yellow flowers, ſucceeded by oblong capſules containing the ſeeds, but do not produce any in this country.

The wood of this tree is in great eſtimation among the dyers, for dying purple and the fineſt blacks, and grows in amazing plenty in the Bay of Campeachy, and other parts of the Spaniſh Weſt Indies, from whence the wood is ſent to Europe as a valuable commodity, and is become a conſiderable branch of trade.

A few of the plants are preſerved here in hot-houſes for variety, where they grow freely, and attain ſeveral feet in height.

It may be propagated by ſeeds procured from abroad, ſowing them in pots, and plunge them in a bark hot-bed: when the plants are three inches high, prick them in ſeparate ſmall pots, and replunge them in the bark-bed in the ſtove.

HALLERIA, African-fly Honey-ſuckle.

One ſpecies, an ever-green ſhrubby plant for the green-houſe, conſtitute this genus.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX is monophyllous, three-parted, and permanent. COROLLA one ringent, or grining petal, having the limb erect and four-parted at the top; the upper part longeſt, blunt, and emarginated; the ſide ones ſhort and pointed; and the lower one very ſhort and acute. STAMINA, two long and two ſhort filaments, and didymous antheræ. PISTILLUM, an oval germen, long ſtyle, and ſimple ſtigma. PERICARPIUM, a roundiſh bilocular berry, and two hard ſeeds.

The ſpecies is;

HALLERIA *Lucida.*

*Lucid or Shining-leaved Halleria.*] Halleria, with a wooddy ſtem, branching ſix or ſeven feet high; oval, ſawed, ſhining green leaves placed oppoſite; and red flowers growing ſcatteringly along the ſides of the branches in June, ſucceeded by roundiſh berries in autumn.

This is an ever-green ſhrubby plant of Africa, requiring ſhelter of a green-houſe here in winter, and muſt be always kept in pots, and managed as other exotics of the green-houſe department, and will make a pretty variety in that collection.

The flowers are of the grining tribe, being formed of one irregular petal cut into four unequal ſegments, and reſemble ſome ſorts of honey-ſuckles. See the *Characters.*

It may be raiſed from ſeed, in a hot-bed in ſpring; alſo by cuttings of its young branches, planted in pots in April, May, or June, and plunged in a hot-bed, giving occaſional ſhade and water.

HAMAMELIS, Witch Hazel.

It furniſhes one hardy deciduous ſhrub for the ſhrubbery.

Claſs and order, *Tetrandria Digynia.*

*Characters.*] CALIX, a triphyllous involucrum, and a double proper cup, or perianthium, having the exterior part of two, and the interior part of four leaves. COROLLA, four long narrow reflexed petals, and four nectariums adhering thereto. STAMINA, four narrow filaments, and horned, reflexed antheræ. PISTILLUM, an oval hairy germen, two ſtyles, and capitated ſtigmas. PERICARPIUM, none. SEMINA, an oval nut ſituated in the calix.

The ſpecies is;

HAMEMELIS *Virginiana.*

*Virginian Hamamelis.*] Hath a ſhrubby or wooddy ſtem, branching three or four feet high; oval, indented, alternate leaves, reſembling thoſe of the common hazel, and flowers growing in cluſters from the joints of the young branches; appearing at the fall of the leaf in November and December, but producing no ſeeds in England.

This is an American ſhrub, of hardy growth; is admitted here in our ſhrubberies to

to increaſe the variety in the collection of hardy ſhrubs in extenſive gardens; but its flowers are more ſingular for their appearance in winter, when the leaves are fallen, than their beauty.

It is propagated by ſeed, and by layers of its young branches.

By Seed.—This is procured from America; ſow it in an eaſterly border, half an inch deep, they will come up the ſecond ſpring, not before, ſo keep the ground clean from weeds till then; when, if the ſeaſon proves very dry, give moderate waterings, alſo in ſummer; and when two years old, tranſplant them in nurſery rows.

By Layers.—In autumn, or even in winter, and early in ſpring it may be done, and the young twigs of the laſt ſummer's ſhoot ſhould be choſen, giving them a ſlit at a joint, lay them in the earth, and they will be rooted, and fit to tranſplant into the nurſery by autumn following.

HEDERA, Ivy, the Ivy-tree.

This Genus furniſhes two ſhrubby climbers, one an ever-green, the other a deciduous plant, both celebrated for their climbing property, in aſcending to the top of the higheſt trees, buildings, or any adjacent ſupport, rooting in the bark of the trees, walls, &c. as they aſcend.

Claſs and order, *Pentandria Menogynia.*

*Characters.*] CALIX, a ſmall many-parted involucrum to each corymbus of flowers, and a five-parted cup to each floret. COROLLA, each floret compoſed of five oblong ſpreading, incurved-pointed petals. STAMINA, five awl-ſhaped filaments, and incumbent Antheræ. PISTILLUM, a turbinated germen, ſhort ſtyle, and ſingle ſtigma. PERICARPIUM, a globular unilocular berry, and five ſeeds.

The ſpecies are;

[1]HEDERA, *Helix.*

*Helix*, or *Common Evergreen Ivy-tree.*] Hath ſhrubby, long, flexible, rooting ſtalks, climbing upon ſupport many feet high, by their cirrhoſe roots emitted from the ſides of the ſtalks and branches, ſtriking root in the bark of trees, walls, &c. as they aſcend; garniſhed with large lobated, and ſometimes oval leaves, and corymboſe cluſters of greeniſh flowers at the ends of the young ſhoots, ſucceeded by round cluſters of berries ripening to a black, and a yellow colour in the varieties.

*Varieties of this are*;] Common black-berried ivy-tree—Silver-ſtriped-leaved ivy——Gold-ſtriped ivy——Yellow-berried ivy.

All theſe varieties are ever-green; they flower in September, and the berries continue their growth all winter, and ripen towards ſpring, which in contraſt with the leaves exhibit a delightful variety; but the yellow-berried kind is rare in this country.

[2]HEDERA, *Quinquefolia.*

*Five-leaved deciduous Hedera, commonly called Virginia Creeper.*] Hath ſhrubby very long ſlender rooting ſtalks, climbing upon ſupport an hundred feet high or more, by their cirrhoſe-roots from the ſides of the ſtalks, ſtriking root in walls, &c. as they aſcend; garniſhed with quinquefoliate deciduous leaves, being compoſed of five oval ſerrated lobes, cloſely covering all the ſtalks and branches in ſummer, dying away to a reddiſh tinge in autumn.

Both the above ſpecies are ſhrubby and durable in ſtem and branches; the firſt and varieties are ever-green; the ſecond is deciduous, dropping its leaves in autumn; are both exceedingly hardy, proſper almoſt any where, and are remarkable for their ſingular property of emitting rooting cirrhi all along the ſides of their ſtalks and branches, ſtriking root in any neighbouring ſupport, thereby climbing to a prodigious height.

The firſt ſpecies, *Hedera Helix*, or common Ivy, is well known to all, by its growing wild in our woods, hedges, and upon old walls and other buildings, &c. eſpecially the common green ſort, which by its climbing ſtalks and branches rooting all along in the bark of the adjacent trees, &c. aſcends and ſurrounds their ſtems, and mount to their tops; alſo over-runs walls, pales, and the whole ſides and tops of houſes, rearing its head often above the chimney, and frequently aſcends to the very top of church-towers in the country; cloſely attaching itſelf to its ſupport by its cirrhoſe-roots emitted from all the ſtalks and ſhoots in their progreſs of climbing; and having reached the top of its ſupport, of whatſoever kind, it there forms a ſhort woody trunk, and large buſhy head. In default of ſupport, it will run upon the ground, branching and rooting as it advances, and ſoon cover a large ſpace; therefore, with reſpect to its uſe in gardening, it may be planted to cover the ſurface of unſightly walls, old pales, and the like; which it will ſoon effect with little trouble; it is alſo excellently

ly adapted to over-run grottos, caves, cots, hermitages, root houſes, artificial ruins, &c. to give them a more rural appearance; likewiſe may be planted here and there in wilderneſſes, cloſe groves, ſhady walks, and other places of ſolitude, to run up large trees; and for variety may ſtation a plant here and there in open ſhrubberies, placing a ſtout ſtake or poſt for it to climb upon, which it will ſoon ſurround and hide, and rear its head above it, and form a thick buſh at top; it may alſo be trained up to a ſtem, and made to form a buſhy head. Thus may the Ivy-tree, though a common wild plant, be employed in our gardens, but its commonneſs rendering it of little eſtimation with moſt, it is ſeldom cultivated: all the varieties, however, are beautiful ever green climbers; the ſtriped-leaved kinds in particular have ſingular elegance, when trained againſt walls in any conſpicuous ſituation; and all the ſorts may be raiſed abundantly by cuttings of their ſhoots, which root freely, make amazing progreſs in growth, and faſten themſelves to any ſupport with very little aſſiſtance.

The ſecond ſpecies, *Hedera Quinquefolia*, is an American plant, but ſo hardy that it will proſper any where, and is a true ſpecies of the Ivy, as it climbs and plants its roots into walls, &c. like that plant; is of ſurpriſing quick growth, frequently ſhooting twenty feet or more in one ſummer, ſtriking root into the joints of walls, mounts to the top of the higheſt buildings, branching and ſpreading widely each way; and as it proſpers in any ſituation, is well calculated to plant againſt any unſightly walls or high buildings, to cover them, and for which purpoſe it is greatly uſed in London, no plant being ſo well adapted, as it will thrive in the midſt of that city, amongſt the cloſeſt buildings, and ſoon reach their tops, covering them effectually with its beautiful five-lobed foliage in ſummer.

*Propagation.*

Both the ſpecies and reſpective varieties are propagated with great facility, by cuttings of their young ſhoots in autumn or ſpring in a ſhady border, which will readily take root, and in one year will form good plants, and may then be planted out for good where they are to remain, or remain longer in the nurſery, as may be convenient; cuttings may alſo be planted at once where they are to remain, and they will alſo ſucceed: the common Ivy may alſo be propagated by ſeeds, ſowed as ſoon as they are ripe, in March or April, which, if kept ſhady and moiſt, will often riſe the ſame ſeaſon.

When any of the ſorts are planted againſt walls, &c. they will only require a little conducting at firſt, juſt to nail their firſt ſhoots thereto, they will afterwards plant their roots firmly in the ſupport, and fix themſelves.

HEDGES, growing fences, employed occaſionally both for uſe and ornament, as outward fences to gardens, and to divide the internal parts of the ground.

Growing Hedge-fences are the cheapeſt, the moſt eligible, and ornamental garden-fences that can be employed in ſuch parts where walls, &c. are not particularly neceſſary for wall-trees, and may in ſuch caſes be employed, both as outward fences to garden-ground, nurſeries, and plantations; as alſo to divide, where neceſſary, the different parts of the ground; in both caſes ſerving as a defence againſt men and beaſts, as well as afford occaſional ſhelter and ſhade to particulars, as effectually as the beſt wall or paling fences.

Several ſorts of ſhrub and tree-plants, both deciduous and ever-greens, may be occaſionally employed for hedges, either as outward fences, and for dividing any internal portion of ground.

*For outward Hedges.*

The white-thorn or haw-thorn-tree, forms the beſt outward hedge-fence in the world; which being properly trained by trimming, or clipping annually, is rendered the cloſeſt and hardieſt fence of any other tree yet known; and being very durable, is preferable to all others for outward Hedge-fences both to gardens and fields; alſo for the diviſions of fields, where they are expoſed to cattle; and for either purpoſe a hedge of this ſort is formed by planting young plants or ſets raiſed from ſeed in the nurſery, which when a year or two old, or as big as a gooſe-quill, are of a proper ſize for this uſe; and the methods of planting them is exhibited hereafter; and for particulars in raiſing the plants, ſee CRATÆGUS.

Hedges of this plant are commonly called quick-ſet Hedges, in a cuſtomary or confined ſenſe, though in a general ſenſe it may with propriety be underſtood of all growing Hedges, to diſtinguiſh them from dead-hedges, formed with ſtakes and buſhes.

The black-thorn, or ſloe-tree, is alſo pro-

per

per to be employed for field Hedges, and forms a very ſtrong durable fence; but by its producing ſuch abundance of ſuckers from the root, widely on every ſide, as to over-run the adjoining ground, renders it the leſs eſteemed for general uſe; as it is however well armed with thorns, it may be rendered a very good outward fence againſt moſt cattle, or to divide fields, &c. and a Hedge of this tree may be raiſed either by ſowing the ſeed, i. e. the ſloes themſelves, in autumn as ſoon as ripe, in the place where you would form the Hedge, in two drills the whole length, a foot aſunder, and an inch or two deep, covering them over with earth; or you may firſt raiſe the plants in a nurſery, or procure young ſetts from the neighbouring hedges, as this plant never fails affording great abundance of ſuckers or ſpawn, which they ſend up annually from its roots; ſo that having procured of either ſort, plant them in one or two rows the whole length of your intended Hedge. See PRUNUS.

The crab-tree, both of the apple and thorny ſorts of plums, are alſo ſometimes planted for Hedges, and will ſoon grow up; obſerving that plants for this purpoſe ſhould be ſuch as are raiſed from the kernels of the true wild crabs, which generally come more thorney than thoſe of the cultivated kinds, and ſhoot more moderate and cloſe, ſo as to be more readily kept within the proper limits of a Hedge; and a Hedge of them may either be raiſed by ſowing the kernels of the fruit in autumn or winter, in the place where the Hedge is intended, in drills the whole length an inch deep, covering them that depth; or may raiſe plants from ſeed in the nurſery, which when a year or two old, plant out for good. See PYRUS and PRUNUS. A Hedge of theſe plants is only recommended as being of quick growth, and in default of better; and beſides its property as a field-fence, ſome plants of the Hedge may be ſuffered to grow up, aud they will afford an annual crop of crabs for verjuice; and a proper number of the plants may be uſed as they ſtand in the Hedge for ſtocks, to graft either with uſeful family apples, or ſorts proper for cyder.

The elder-tree is alſo frequently uſed for outward Hedges, eſpecially when a fence is wanted as ſoon as poſſible, as it will form the moſt expeditious Hedge-fence of almoſt any tree in the world, though not the moſt effectual nor beautiful; however, where an immediate outward Hedge-fence is required to any out-ground, or plantation, the elder may be made to form a good one in one year, by planting large truncheons, or cuttings of the ſtraighteſt upright ſhoots and branches, from two or three, to ſix feet long, planted either upright a foot diſtance, and wattled along the top to preſerve them firm and even; or may be placed ſlanting acroſs one another chequerwiſe, forming a ſort of lattice-work, which will be the moſt effectual method. In either method of planting, ſharpen the lower ends of the cuttings, making holes to receive them fifteen or eighteen inches deep, either in level ground, or the ſides or tops of banks; they will ready emit roots, and ſhoot ſtrongly at top the ſame year; but for their general propagation, ſee SAMBUCUS.

The alder-tree is alſo proper to plant for Hedges in wet or marſhy ground, as being an aquatic, and will grow by ſmall or large cuttings like the elder, and will ſoon form a fence; and where Hedges are neceſſary by the ſides of rivers, brooks, or other water, this tree is very proper; as its roots and numerous ſuckers ariſing from their lower parts, form ſuch a cloſe thicket, as effectually to preſerve the earth of the banks from being undermined and waſhed away. See BETULA ALNUS.

Holly forms an excellent and moſt beautiful hedge, and is the beſt ever green Hedge that can be planted for an outer Hedge-fence; for it grows very cloſe, and is well furniſhed with leaves, which being armed with thorns, no cattle will brouze upon them; and being always in foliage, affords good ſhelter in winter, and appears ornamental at all ſeaſons. The only objection to a holly Hedge for general uſe, is its flowneſs of growth the firſt four or five years, as rooting but moderately; but when once it has eſtabliſhed itſelf, it makes amends by its progreſs in height, ſtrength and thickneſs; and, as a fence, is equal, if not ſuperior to any other Hedge whatever; and for beauty, may be ſaid to ſurpaſs all, if neatly trained by clipping once or twice annually in ſummer. A Hedge of this ſort is formed either by ſowing the ſeeds at once in the place where you intend to have the hedge, in drills an inch and half deep; or by planting young plants of two or three years old from the nurſery, which is rather the moſt eligible practice, planting them in one or two rows, tho' two rows planted a foot aſunder, and the ſame in each row, will form the thickeſt hedge; but either of which will

in

in eight, nine, or ten years form a good fence. For particulars in raiſing the plants, ſee ILEX.

The furze plant is ſometimes uſed for an outward ever green Hedge fence for fields, which, however, makes but an indifferent hedge, being apt to die off in gaps; but as it will grow upon dry banks, or any poor dry ſoil, where ſcarcely any other plant will thrive; it may on that conſideration be uſed for a hedge; which is to be effected by ſowing the ſeeds in autumn, at once in the place where it is deſigned to have the Hedge, in drills an inch and a half deep. See ULEX.

With reſpect to the method of planting the above kinds of Hedges, take the following hints:

All outward Hedges deſigned as fences, ſhould have a ditch and bank; the ditch to be on the outſide, three or four feet wide at top, three deep, ſloping to one wide at bottom, raiſing a low bank on the inſide on which to plant the Hedge, which may be planted either on the ſide of the ſaid inner bank, in two rows one above the other, a foot aſunder, as commonly practiſed for quick Hedges, planting them as you advance in forming the ditch and bank; or may be planted entirely on the top of the bank, firſt forming the ditch and bank, and levelling the top of the bank, ſo as to form a ſort of border; then plant the ſets in one or two rows, the whole length; but two rows a foot aſunder, is the moſt eligible for all outward fences, as it always forms the thickeſt, ſtrongeſt, and moſt effectual Hedge-fence; but the particular method is exhibited below.

As the haw-thorn or white-thorn Hedges, commonly called quick, or quick-ſet Hedges, are the moſt effectual and moſt frequently uſed outward Hedge fence, we will therefore firſt exhibit the method of planting and forming theſe kind of Hedges as outer fences againſt cattle, &c. which to render it more effectual, ſhould always have a ditch and bank as above obſerved; the plants or ſetts for forming the Hedge, are raiſed from the ſeed or haws, as directed under their proper genus. See CRÆTÆGUS *Oxyacantha*; and when from one to two or three years old, about the ſize of a gooſe-quill, or a little more or leſs, are proper ſets for planting out to form Hedges, as obſerved in their propagation. Having your quick ready, then in the place where you intend to plant the Hedge, mark out a ſpace for a ditch, three or four feet wide at top, as before obſerved; which is to be digged three feet deep each ſide, ſloping gradually to a foot wide at bottom, forming a bank along upon the inner edge, on which to bed or plant the quick, which ſhould be planted as you advance in forming the ditch and bank; therefore, having lined out the width of the ditch, then along the inner edge lay a row of ſquare ſpit-turfs graſs-ſide downwards, to form the beginng of the bank, backing it up with ſpits of earth from the formation of the ditch, and top it with a little of the fine mold or crumbs, and then upon this proceed to lay the firſt row of quick: firſt let the ſets be headed to about five or ſix inches, and the roots trimmed, then lay them upon the bed of turf, with their top-ends outward, in an upward direction, about ten or twelve inches aſunder; covering their roots with mould alſo out of the ditch, and then lay another row of turf along upon the necks of the plants, and more mould from the ditch upon, and behind the turf; and when the bank is thus raiſed a foot above the row of ſets, plant another row in the ſame manner, placing each ſet againſt the ſpaces of thoſe of the firſt row, ſo covering them with more earth from the ditch, forming it in a flat bed over the ſets, four or five inches deep; continuing the ditch to the depth of three feet, ſloping each ſide, to one foot width at bottom, and trim up all remaining earth, throwing a ſufficiency behind the top of the banking, to back up the whole even, in a ſort of broad border, all the way along the top, ſloping a little back ſo as to correſpond nearly with the adjoining ground.

But in planting the above kind of Hedge, or any other ſort, for an outward fence, &c. ſome form the ditch and bank firſt, as above, and plant the ſets in two rows along the top; that is, after having formed the ditch and bank, then levelling the top, forming a ſort of border all along a yard wide; plant the ſets along the middle thereof upright, in two rows a foot aſunder, and ſix inches diſtant in each row; the mode of planting to be as hereafter directed; obſerving the ſame when intended to raiſe a Hedge at once from ſeed, ſowed where you deſign the Hedge to be, ſowing them along the top in drills a foot aſunder.

Sometimes when Hedges are deſigned for middle fences to divide fields, a two-ſided bank is raiſed a yard high, and as broad at top, having a ſlight ditch on each ſide; and each

each ſide of the bank is formed with ſquare ſpit-turfs, from the adjoining ground, and the middle filled up with mold from the ditches on each ſide; ſo that, when finiſhed, it forms a yard-wide border all the way along the top; and along the middle of which plant two rows of Hedge-ſets, or ſeed, in drills as before obſerved.

But in places where no ditch, nor raiſed bank is required, as may be the caſe for middle Hedges, in the more interior parts of grounds, eſpecially in gardens; then the place for the Hedge being marked out on the level ground, two or three feet broad, dig it along, one good ſpade deep at leaſt; and then plant your ſets of any ſort in two rows, ranging along the middle, as hereafter directed; or, if you deſign to ſow ſeeds, &c. of any ſort at once, where you intend to have the Hedge, ſow them in two drills, a foot aſunder, the whole length.

Having given directions above for the method of planting the ſets of quick upon the ſide of a ditch and bank, the following hints are of the particular manner of planting any ſorts upon level ground.

With reſpect, therefore, to the particular mode of planting the ſets, or plants of any ſort, for a Hedge upon level ground, either on the top of a bank levelled, or entirely upon the general level ſurface, where no bank is neceſſary, as for middle Hedges in gardens, &c. the following methods are practiſed.—Thathaving, in the place where the Hedge is intended, either upon the top of a bank, or general level, formed a ſort of level border, two or three feet wide the whole length, you may form one or two ſlight narrow trenches, along the middle, for the reception of the ſets; that is, either cut out a narrow trench, ſix or eight inches deep, all the way along, for each row of ſets, making one ſide of each trench upright, as practiſed in planting box-edgeings, ſee Buxus; then place the ſets in the trench againſt the upright ſide, eight or ten inches aſunder, and turn the earth in upon their roots as you go on, and tread it cloſe thereto; and then, if you deſign to plant two rows to form a double Hedge, make another trench a foot from the firſt, and plant it in the ſame manner; or, inſtead of the above method of planting the ſets, they may be trenched in by digging a foot-wide trench all the way along, placing the ſets therein as you go on, in the following manner: with your ſpade chop out, or mark out a trench a foot wide; then, having the plants, begin at one end, dig out a ſpit the width of the trench, and then plant one or two ſets cloſe to the ſides of the trench: but if intended to have a double Hedge, place two ſets ſo as to form two rows; then dig another ſpit, and turn the earth upon their roots; then place two more ſets in the ſame manner, at eight or ten inches diſtance from the firſt two, and turning another ſpit of earth upon them; after theſe two more at the ſame diſtance; and in this manner proceed digging along, and planting the ſets as you advance, till the whole is finiſhed.

In reſpect to the training and general culture of theſe ſorts of Hedges, it muſt be remarked, that all ſuch that are expoſed to cattle, muſt, as ſoon as planted, be fenced either with a ſtake and buſh Hedge, with hurdles, or with rails and open paling, four or five years till the hedge grows up; obſerving not to place the fence too cloſe to the Hedge to interrupt its growth. The Hedge muſt alſo be duly weeded while young, and this ſhould be particularly attended to the firſt two years.

And if deſigned to train the Hedge regular by clipping it with garden ſhears, it ſhould be annually performed in ſummer, obſerving however to top it but ſparingly while it is young, until arrived at its intended height, only juſt trim off the tops of the ſtraggling ſhoots to preſerve a little regularity, and promote lateral wood to thicken it as it advances; and cut it in alſo moderately on the ſides; but when arrived at nearly its proper height of four, five, or ſix feet or more, then trim it cloſe on the ſides and top, annually to preſerve it thick and within its proper bounds, cutting the ſides always firſt as even as poſſible; then the top, which ſhould alſo be cut as even as a line, always cutting in nearly to the old wood of the former year's cut, otherwiſe your Hedge will get too broad, and keep always the top narrower than the bottom.

But as to field Hedges, which are rarely clipped, they grow naked or open at bottom, and will want plaſhing or laying every ſeven, eight, or ten years, to preſerve them thick at bottom, to anſwer the purpoſe of a fence. See Plashing Hedges.

*Internal Hedges, both as Fences and for Ornament.*

Having mentioned above the various ſorts of plants proper to be employed for outward

Hedges, either for gardens or fields, for the purpoſe of ſtrong fences, we now proceed to point out the ſorts for internal or middle Hedges in gardens, either as fences or to form ſhelter, and for ornament.

In former deſigns for gardens, regular Hedges were in great requeſt; almoſt all the different compartments and diviſions of pleaſure-grounds were ſurrounded with Hedges formed of various ſorts of trees and ſhrubs, both ever-greens and deciduous kinds, which being neatly trained and clipped once or twice annually, appeared ſometimes very ornamental in themſelves; but as they ſhut out from view, the various plants and trees growing in the quarters, which were infinitely more agreeable, as garden furniture, than the perpetual ſhew of ſo much Hedge-work obtruding always upon the ſight, they are now almoſt totally excluded our gardens, for they at one time ſo greatly prevailed by way of ornament, that they bounded all the walks, that whereſoever one walked, cloſe Hedges preſented themſelves ever in view on both ſides of the walk, ſix or eight feet high, ſhutting out all other objects from ſight, that it was like walking in a lane between two walls; and the beauty of the internal plantations were loſt to perſons in the walks. The error of ſo many ſurrounding Hedges were ſo evident to perſons of taſte, beſides their ſtiff formal appearance, and expenſiveneſs to keep in order, that they were baniſhed from moſt gardens; and in modern deſigns, conſulting proſpect and rural diſpoſition in imitation of nature, nothing of Hedge-work is admitted, except merely as fences, or for ſhelter, or to hide any diſagreeable object; however, for the ſake of variety ſome Hedge work for ornament might ſtill be introduced in large gardens, in contraſt with rural deſigns, as a little of regular and a little of rural performances in different parts of the garden, will diverſify the general ſcene; obſerving, however, Hedges ſhould be but ſparingly admitted, and never to bound walks, nor ſurround entirely any compartments furniſhed with curious trees or plants, except by way of fence, or for ſhelter, or ſhade where neceſſary.

Tall Hedges of elm, beech, lime, and other deciduous trees, trained forty or fifty feet high or more, were in great repute at one time for ornament, and ſometimes were ſo ſtationed as to exhibit an air of grandeur; but their great height rendering them very expenſive, and troubleſome to clip, they are moſtly diſcontinued.

Hedges in ancient deſigns were alſo formed into various devices of rural architecture, pavilions, cabinets, porticoes, galleries, and other regular performances, which greatly prevailed, and were often trained ſo as to exhibit an air of magnificence as garden furniture; but were as often ſo ill formed, according to the deſign they repreſented, that they were offenſive to ſight, and were rooted out of many gardens, though ſomething of this nature might be introduced with moderation for variety.

As ſeveral different ſorts of trees and ſhrubs, both ever-greens and deciduous plants, are employed in forming garden Hedges, the principal of them are exhibited below, under the heads, Ever-green Kinds, and Deciduous Kinds.

*Ever-green Kinds.*

The principal ever-greens employed for Hedges are:—Holly—Yew—Laurel—Lauruſtinus—Phillyrea—Alaternus—Bay—and Ever-green Oak; all of which will form Hedges from five or ſix, to ten or twelve feet high; and the laſt named ſort, Ever-green Oak, may be lead up to twenty feet: but the holly and yew form conſiderably the beſt Hedges for general uſe. Beſides the above ſeven ſorts for tall Hedges, ſometimes alſo are uſed for lower Hedges:—Ever-green Privet—Tree Box—Juniper—Virginia Cedar—Savin—Roſemary—Pyracantha—and Sea Purſlane Shrub, and ſome other ever-greens of ſimilar growth.

Of the above liſt of ever-greens for Hedges, the holly and yew form the cloſeſt and moſt effectual garden-hedges of any of the ſorts, as they will grow ſo thick and cloſe, that a bird can hardly get into them, and may be trained ten or twelve feet high, or more; tho' from about ſix to eight or nine feet, is the moſt eligible height for theſe kinds of Hedges for general uſe: both the ſorts may be eaſily trained to almoſt any form by an annual clipping, more particularly the yew; but the holly makes rather the moſt eligible Hedge as a fence, and alſo for ornament; but is ſingularly beautiful when the common green ſorts and the variegated kinds are alternately intermixed. The yew, however, as producing the moſt numerous cloſely-placed ſmall ſhoots, thickly ſet with very ſmall leaves, grows

grows the cloſeſt, and is the moſt eaſily trained into any deſired ſhape, of any Hedge in being, as is evident in ſome old gardens, where many of theſe hedges are ſtill retained, exhibiting the remains of the ancient taſte of deſign in gardens; in which ſome are trained into common regular Hedges, and ſome have the hedge-work formed into various ſhapes and figures; as arcades, niches, cornices, porticoes, pilaſters, galleries, figures of men, beaſts, and birds, and many other formal works of art. The yew is alſo a very proper Hedge to plant internally in nurſery grounds for ſhelter to young plants.

To form internal or middle Hedges of theſe two ſorts, plant them in one row, which is ſufficient, along the place where the Hedge is intended; placing the holly at about a foot or a foot and a half diſtance, and the yew the ſame, but if ſpreading plants, two or three feet.

The laurel being a ſingularly beautiful ever-green, adorned with noble large foliage, is ſometimes planted for Hedges; but as it ſhoots vigorouſly, it never grows ſo compact, nor is ſo eaſily kept in form as the two forementioned ſorts; its leaves alſo being very large, when the hedge is clipped with ſhears, they are unavoidably cut through, and ſo ſtubbed and mangled as to have a very diſagreeable appearance; therefore, inſtead of performing their annual training with ſhears, ſome trim off the ſhoots with a knife, to preſerve the leaves entire. This plant is alſo proper to train Hedge-faſhion to hide any diſagreeable fence, and will grow either under trees in the ſhade, or in an open expoſure, and is of quick growth; and to form a Hedge, may be planted in one row, at about eighteen inches to three feet diſtance, according to the ſize of the plants at the time of planting.

The lauruſtinus, being valuable not only as an ever green, but as one of our moſt beautiful flowering ſhrubs, will form a delightful Hedge for ornament, as it will be covered with flowers in winter and ſpring; it is alſo excellently adapted for training hedge-faſhion againſt any ſhabby fence or naked wall. Planting it in either method, in one row, at from about eighteen inches to three feet diſtance.

The phillyrea and alaternus are very beautiful ever-greens for ornamental Hedges, both of which plants greatly reſemble each other; but the phillyrea being the ſtrongeſt grower, as well as thickeſt ſhooter, is the moſt eligible for a hedge, but for variety both may be uſed: they are alſo ſome of the beſt ever-green ſhrubs for training hedge faſhion, againſt any unſightly or naked wall or paling fence, which they will ſoon cover; and if the common green and variegated kinds are intermixed, in either mode of hedge-work, they will have a delightful effect, and may be trained as detached Hedges, ſix or eight feet high, and againſt any fence ten or twelve.

Plant them in one row, at from about fifteen or eighteen inches to two or three feet diſtance between plant and plant.

The bay will alſo form a tolerable ever-green Hedge for variety, and may be led up ſix or ſeven feet high; placing the plants half a yard diſtance.

The ever-green oak is a proper plant to form a tall hedge, as it may be trained fifteen or twenty feet high, if required; plant it in one row, ſetting the plants one, two, or three feet aſunder, according to their ſize.

The ever-green privet will alſo form a tolerable good Hedge five or ſix feet high, planting the ſets about a foot aſunder, and train it up narrow at top.

The tree-box makes a very cloſe and beautiful low ever-green hedge, about four or five feet high, planting them a foot aſunder.

The other leſſer ſorts of ever-greens mentioned in the liſt for ever-green Hedges, are ſometimes employed for variety to form moderate Hedges, at from about three or four to five or ſix feet high; planting them in a row at about from twelve or eighteen inches to two feet aſunder.

All the ſorts of ever-greens here ſpecified for Hedges, are raiſed for ſale at all the nurſeries; and when from about twelve or eighteen inches to two or three feet high, are of proper ſize for that purpoſe.

The ſeaſon for planting them is in autumn or in ſpring; for it is not ſafe to tranſplant ever-greens in the middle of winter.

With reſpect to the mode of planting all the above ſorts of ever-greens, for middle or internal Hedges; no ditch nor bank is neceſſary, as for outward Hedges for fences; ſo that in the place where the Hedge is deſigned, mark out a ſort of border the whole length, two or three feet wide, and dig or trench it all the way along, for the reception of the plants: the plants need only be planted in a ſingle row; obſerving, that if the plants are ſmall, and that you would have them meet and form a hedge as ſoon as poſ-

ſible, you may plant them at from about a foot to fifteen or eighteen inches aſunder; but if the plants are two or three feet high, and proportionably ſpreading, from about eighteen inches to two or three feet, may be a proper diſtance; and as to the method of planting, if they are ſmall plants, they may be planted in trenches as directed in planting Hedges for fences; but if large plants with ſpreading roots, they may either be trenched in as you proceed in digging the ground, or holed in, plant and plant; the opening of one hole fills up that immediately before it, about the roots of the plant placed therein; and ſo proceed hole and hole to the end, placing all the plants upright, at regular diſtances, tread the earth cloſe about their roots, and make their heads range evenly.

*Deciduous Kinds.*

The proper deciduous trees and ſhrubs for internal Hedges in gardens, beſides the ſorts already treated of for outward Hedges are: Hornbeam—Beech—Elm—Lime-tree—and Alder: all of which are proper either for middling or tall hedges, as they may be trained up from about ſix or eight to fifteen or twenty feet high; and the elm to double that height, if required. Privet is alſo ſometimes uſed for moderate Hedges. And for low Hedges the Roſe—Sweet-briar—Honeyſuck—Syringa—Berberry, and ſeveral other low-growing deciduous ſhrubs, for variety.

The hornbeam forms one of the moſt beautiful ſummer Hedges of the deciduous tribe, it being a moderate, but very cloſe ſhooter, well furniſhed with leaves; and may be trained up from about ſix or eight, to twelve or fifteen feet high; but the leaves, although they wither in autumn, remaining firmly attached to the branches all winter, they make but a ſhabby appearance during that ſeaſon: it is, however, a fine Hedge, and the ſingularity of its retaining its withered leaves in winter, renders it ſuperior to moſt other deciduous Hedges for the purpoſe of forming ſhelter in the winter time, ſee CARPINUS. Plant it for a Hedge in a ſingle row, at about half a yard aſunder, if required to form a cloſe moderate Hedge as ſoon as poſſible; but if you deſign to lead up the Hedge pretty tall, ſet the plants about three or four feet diſtance.

The beech alſo forms a very cloſe regular Hedge, from about ſix or eight, to fifteen or twenty feet high: the leaves withering on the branches in autumn, continue dropping off moſt part of the winter. Plant it as directed above for the HORNBEAM.

The elm will form a very cloſe, even, and beautiful Hedge, provided the upright Engliſh elm is planted, it being the propereſt of all elms for this purpoſe; and may be trained from ſix or eight, to thirty or forty feet high, forming a cloſe Hedge from the very bottom to top. It is planted in a ſingle row, from about a yard to ſix or eight feet diſtance; but when required to form a cloſe middling Hedge as ſoon as poſſible, you may ſet the plants but two feet or a yard aſunder; and if intended for a moderately tall Hedge, plant them three or four feet apart in the row; and if deſigned to have a Hedge of conſiderable height, place the plants five or ſix feet diſtance at leaſt, but if eight or ten the better; as, if the plants of a very tall Hedge ſtand too cloſe, they are apt to get naked at bottom.

The lime-tree is ſometimes employed for ornamental Hedges for variety, but is greatly inferior to any of the other deciduous kinds, as it becomes thin and ſhabby by clipping, and is thinly leaved; which alſo begin to fall off very early in autumn.

The alder, as it delights in moiſt ſoils, and watery places, is ſometimes planted for Hedges in low moiſt parts of gardens, where other trees will not proſper, and makes a handſome Hedge, from about ſix or eight, to twelve or fifteen feet high, retaining its leaves late in autumn, and continuing a fine green to the very laſt. See BETULA ALNUS.

Privet is frequently planted for Hedges, as it grows exceedingly cloſe, may be trained up five or ſix feet high, and will grow any where; either in an open expoſure, or in the ſhade, or under trees, and even in the midſt of great cities, and ſoon grows up.

As to the other low kinds of ſhrubs mentioned in the liſt of deciduous garden Hedges, they are ſometimes employed for variety, and ſome ſorts, ſuch as roſes, honeyſuckles, and ſyringa, formed into low Hedges, will, beſides their property as Hedges, produce vaſt quantities of flowers.

With reſpect to the method of forming all theſe kinds of deciduous Hedges, the plants for that purpoſe are all raiſed as directed under each reſpective genus, or may be had from the nurſeries; and when from about one foot to a yard or more high, according to the ſorts, are of a proper ſize for that purpoſe; for it is eligible to plant them young, chuſing

chuſing ſuch that are well furniſhed all the way with plenty of ſide or lateral ſhoots, that they may form a cloſe Hedge quite from the bottom; and all of which may be planted any time from October till March, in open weather.

As to the method of planting, nearly the ſame is to be obſerved as directed for the ever-green kinds.

*Of Training the above different Sorts of Hedges.*

As to the method of training the Hedges, both ever-green and deciduous kinds, they, while young, muſt be but ſparingly topped, till they arrive at their intended height: cutting each ſide, however, moderately every ſummer with garden ſhears, to train them in the proper form, and cauſe them to throw out plenty of lateral wood to thicken; but as to the top, only juſt trim the ends of the running ſhoots a little even, and to promote their emitting latterals to thicken gradually as they advance in height; and as ſome plants will advance conſiderably faſter in height than others, let thoſe be trimmed within the bounds of regularity, which is all that ſhould be done till the Hedge has attained nearly its deſigned height: obſerving in training up the different Hedges to keep the top gradually a little narrower than the bottom; but more particularly thoſe of the moſt pliant growth, eſpecially ſome of the ever-green kinds, otherwiſe when broad at top, they catch much ſnow in winter, the weight of which would break the more pliant ſorts much out of form.

All full trained Hedges, in order to preſerve them in proper form, cloſe and neat, muſt be clipped, both on the ſides and top, once or twice a year, but never leſs than once; and the beſt time of the year for this work is ſummer, from about the middle or latter end of June to the end of Auguſt; for then the Hedges will have made their ſummer ſhoots, which ſhould always, if poſſible, be clipped the ſame ſeaſon while in leaf, and before the ſhoots become hard, whereby you will be able to perform the work more expeditiouſly, and with greater exactneſs; for regular Hedges ſhould be cut as even as a wall on the ſides, and the top as ſtraight as a line: obſerving after the hedge is formed to its proper height and width, always cut each year's clipping nearly to the old cut of the former year, particularly on the ſides, for by no means ſuffer them to grow above a foot or two wide, nor ſuffer them to advance upon you too much at top, where it is deſigned, or neceſſary to keep them to a moderate height.

But to keep Hedges in perfect good order, they ſhould be clipped twice every ſummer: the firſt clipping to be about Midſummer, or ſoon after, when they will have made their ſummer ſhoot; and as they will ſhoot again, what may be called the autumn ſhoot, the ſecond clipping is neceſſary towards the middle or latter end of Auguſt, and they will not ſhoot again that year.

However, when it does not ſuit to clip them but once in the ſummer, the clipping ſhould not be performed until the beginning of Auguſt; for if cut ſooner, they will ſhoot again, and appear almoſt as rough the remainder of the ſummer and all winter as if they had not been clipped at all.

Very high Hedges are both troubleſome and expenſive to cut. The clipping is ſometimes performed by the aſſiſtance of a high machine-ſcaffolding, or ſtage, twenty or thirty feet high, or more, having platforms at different heights for the men to ſtand upon, the whole made to move along upon wheels: it is compoſed of four long poles for uprights, well framed together, eight or ten feet wide at bottom, narrowing gradually to four or five at top, having a platform or ſtage at every ſeven or eight feet height, and one at top of of all; and upon theſe the man ſtands to work, each platform having a rail waiſt-high to keep the man from falling; a ſort of a ladder formed on one ſide for the men to aſcend, &c. and at bottom four low wheels to move it along: upon this machine a man may be employed on each ſtage or platform, trimming the Hedge with ſhears, and ſometimes with a garden hedge-bill fixed on a handle five or ſix feet long, which is more expeditious, though it will not make ſo neat work as cutting with ſhears; ſo as they proceed in cutting, the machine is moved along upon its wheels. But ſometimes, inſtead of the above machine, high clipping is performed with multiplying ſpring, or ballance-ſhears: i. e. ſhears fixed nearly horizontal upon the end of a long pole, ſix, eight, or ten feet long, and which is made to fix into another occaſionally, by means of iron rings, and this into a third, &c. according as you advance in height with the clipping; ſo that the ſhears by means either of a ſpring, or by a knob of iron forged to the back of the lower blade, for a weight, are made to open of themſelves,

themſelves. Then having a long ſtring reaching from a ſmall bent iron handle of the ſhears, all the way down the ſides of the poles through ſmall rings; and by holding the pole in one hand, reſting the lower end on your knee or foot, and pulling the ſtring, the ſhears are ſtruck cloſe, ſo as to cut the ſhoots of the Hedge; and at each ſtroke the ſhears open again, ready for another: this however is very tedious, as well as tireſome to the workman, and only the ſides of the hedge can be trimmed; but theſe very high hedge-works, on account of the great trouble of clipping, and the preference given to rural growth, are become in diſrepute; and, in moſt places, the trees which formed them are ſuffered to grow in an open natural way.

HEDYSARUM, French Honeyſuckle.

The plants are principally of the herbaceous tribe; and there are many ſpecies, but not more than two common to the Engliſh gardens; a hardy biennial and perennial, both of the flowery race, producing ſtalks two or three feet high, adorned with pinnated and trifoliate leaves, and papilionaceous flowers in long ſpikes.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous and half five-parted. COROLLA is papilionaceous of four petals, an oblong oval, compreſſed, emarginated, reflexed vexillum; two oblong, narrow, erect wings, and an obtuſe carina, bifid at the baſe. STAMINA, ten diadelphous filaments, and roundiſh antheræ. PISTILLUM, a ſmall narrow germen, awl-ſhaped, reflexed ſtyle, and ſingle ſtigma. PERICARPIUM, a jointed pod, each articulation containing one reneforme ſeed.

The ſpecies commonly cultivated in our gardens are:

[1]HEDYSARUM *Coronarium.*

*Common biennial French Honeyſuckle.*] Hath large deeply-ſtriking biennial roots; upright, hollow, ſmooth, very branchy ſtalks, three or four feet high, garniſhed with pinnated leaves, of five or ſix pair of foliola, terminated by an odd one; and from the places of the leaves, long ſpikes of beautiful red flowers, ſucceeded by jointed ſeed-pods.

*Variety.*] With white flowers. Both theſe varieties are biennial, riſing one year from ſeed, flowers the next, and then periſh.

[2]HEDYSARUM *Canadenſe.*

*Canadian perennial Hedyſarum.*] Hath long deeply-penetrating perennial roots, crowned with ſimple radical leaves, ſlender ſtalks two feet high, garniſhed with trifoliate or three-lobed leaves, and long looſe ſpikes of flowers from the ſides and ends of the branches, ſucceeded by jointed triangular ſeed-pods.

*Varieties.*] Canadian hedyſarum, with red flowers—with white flowers—and with purple flowers.

Both theſe ſpecies of *Hedyſarum* and reſpective varieties flower in June and July, are exceedingly floriferous, particularly the biennial ſort, and are productive of plenty of ripe ſeed in autumn, and from which all the ſorts may be raiſed abundantly in the common ground.

The firſt ſpecies and variety are biennials, and very ornamental plants for large borders, and to intermix in the ſhrubby compartments, allowing them room, for they branch out greatly every way, producing a vaſt profuſion of flowers; obſerving, as both the varieties are biennial, a ſupply muſt be raiſed annually from ſeed.

The ſecond ſort and varieties are perennial in root, but annual in ſtalk: they are proper ornaments for large flower borders, and to interſperſe in the ſhrubbery clumps: allow them a dryiſh ſoil.

*Propagation, &c.*

All the ſorts are propagated by ſeed, ſowed in March or April, in a bed or border of common earth, for tranſplantation.

Sow each ſort ſeparate, either in drills half an inch deep, or on the ſurface, and rake them in. When the plants are come up two or three inches high, prick them out into another bed or border, ſix inches aſunder, giving water directly, and repeat it as occaſion requires, till they have taken root, and begin to grow: here let them ſtand till October, then tranſplant them into the places where they are to remain to flower, which they will effect the following ſummer.

Obſerve that as the biennial ſort totally periſh ſoon after flowering, a freſh ſupply muſt be raiſed from ſeed every ſpring; but the perennial ſort being abiding in root, ſends up new flower-ſtalks annually.

HELIANTHUS, *Sun-flower.*

This genus compriſes ſeveral hardy herbaceous flowery annuals and perennials, and an eſculent root; moſt of them riſing with upright ſtrong ſtalks, ſeveral feet high, adorned with large ſimple leaves, and terminated by large compound radiated flowers.

Claſs

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX is compoſed of many oblong imbricated leaves, broad at their baſe, and pointed at the top. COROLLA is a compound radiated flower, having numerous tubular hermaphrodite fruitful florets in the diſk, and the border or radius compoſed of long, flat, female, barren florets. STAMINA, five crooked filaments in each hermaphrodite floret, and tubulous antheræ. PISTILLUM, in the hermaphrodites, an oblong germen, ſlender ſtyle, and reflexed ſtigma. PERICARPIUM, none; an oblong four-cornered ſeed, ſucceeds each hermaphrodite floret, reſting on the general receptacle.

This genus compriſes—The Annual Sunflower—Perennial Sun-flowers—and the Jeruſalem Artichoke.

The ſpecies principally cultivated in our gardens are:

[1]HELIANTHUS *Annuus.*

*Annual Sun-flower.*] Hath large fibrous roots; an upright ſtrong ſtalk, riſing from about half a yard, to ten or twelve feet high, branchy near the top, garniſhed with large oblong heart-formed trinervous leaves; and the main ſtem and every branch terminated by one large radiated yellow flower, nodding a little downward.

*Varieties.*] Giant Sun-flower, growing from about five or ſix to ten or twelve feet high—Dwarf Sun-flower, growing from about half a yard to a yard high; and of each variety there are ſingles, and doubles, with deep yellow flowers, and with ſulphur-coloured flowers: the doubles of each ſort are very beautiful, and are rendered double by the radius, ſee COMPOSITUS *flos.* They all flower in July, Auguſt, and September.

[2]HELIANTHUS *Multiflorus.*

*Multiflorus* or *Many-flowered perennial Sunflower.*] Helianthus with fibrous perennial roots, many upright ſtalks, branching numerouſly three or four feet high, garniſhed with heart-ſhaped leaves below, and oval above; and all the ſtalks, branches, and ſide ſhoots, terminated by largiſh bright yellow flowers.

*Varieties.*] Single-flowered perennial Sunflower—Double perennial Sun-flower, rendered double by the radius.

This ſpecies is the common perennial Sunflower, ſometimes called Everlaſting Sunflower; a very floriferous plant, continuing a conſtant ſucceſſion of bloom from July until November; the double-flowered variety is the moſt valuable; the flowers being perfectly full and doubled to the very centre.

[3]HELIANTHUS *Decapelus.*

*Ten-petalous Perennial Sun flower.*] Produces many ſtalks three or four feet high, ſpear-ſhaped leaves, and yellow flowers, having but ten petals in the radius.

[4]HELIANTHUS *Giganteus.*

*Giant Perennial Sun-flower.*] Produces many erect ſtalks, eight or ten feet high, ſpear-ſhaped, alternate leaves, rough and ciliated at the baſe, and many ſingle yellow flowers; having about twenty petals in the radius.

[5]HELIANTHUS *Atro-Rubens.*

*Dark Red diſked Perennial Sun-flower.*] Produces ſeveral ſtalks three or four feet high, garniſhed with oval, crenated, trinervous leaves, and flowers having dark red middles, and the calycinal ſcales erect.

[6]HELIANTHUS *Tuberoſus.*

*Tuberous-rooted Perennial Sun-flower, commonly called Jeruſalem Artichoke.*] Hath a large tuberous, knobbed, irregular, eatable root, like a potatoe; upright ſtalks, ſix or eight feet high; large oval-cordate triple-nerved leaves, and the ſtalks terminated by ſmalliſh yellowiſh flowers.

The flowers of all theſe ſpecies are of the compound radiated kind; many tubular florets compoſe the diſk, and long flat ones the radius or circumference, and which, in the annual ſort in particular, is ſucceeded by abundance of fine large ſeed in autumn, occupying the whole diſk, or middle of the flower; for the female florets in the radius being imperfect, are never followed by ſeeds. See the *Characters.* The name Sun-flower, is chiefly derived from the annual ſort, which is ſaid to be given, becauſe the flower obeys the motion of the ſun, turning with its face always thereto, but more probably from the reſemblance of its rays, to the figure of the radiant beams of that planet.

All the ſorts, except the laſt, have fibrous roots, and by which the perennial ſorts multiply greatly; but the ſixth ſort hath a knobby fleſhy root, which alſo multiplies exceedingly, ſo as often to become troubleſome like a weed: the annual ſorts are but of few months duration; but the perennials are of great duration in root, but annual in ſtalk.

They are all originally of America; but have been long in our gardens, eſpecially the firſt, ſecond, and ſixth ſpecies, and are all ſo hardy as to grow here in any ſoil and expoſure.

They

They are proper ornamental furniture for the common compartments of the pleaſure-ground, arranging them rather backward, among the taller claſſes, where they will effect a good variety with their bloom, in one or other of them, from July until November.

The annual ſorts are ſtately majeſtic plants, of amazing quick growth, as ſome of the giant ſorts will ſometimes in a ſtrong rich ſoil, arrive at ten or twelve feet height in four months, and produce flowers from ten or twelve to eighteen inches diameter, and make a noble appearance, eſpecially the full double kinds. But the dwarf kind being rather remarkable for having the moſt doubles, and theſe generally more double than the giant ſorts, they are the moſt eſteemed for general culture, and are more particularly adapted for ſmall gardens; though in large gardens ſome of each ſort is proper: and both varieties, if growing ſeparate, remain tolerably permanent, as the ſeed of each will produce plants of the ſame ſort again.

Theſe fine plants are of no more than about ſix months duration, being raiſed from ſeed in ſpring, arrive at full growth in July and Auguſt, and die wholly in October or November; ſo that a freſh ſupply muſt be raiſed every ſpring.

All the perennials are of great duration in root; but their ſtalks decay in autumn, and new ones riſe in ſpring.

Of the perennial ſorts, the *Helianthus Multiflorus* has conſiderably the greateſt merit for ornament, the flowers being larger and more numerous than any of the others, and very double, and is the ſort commonly cultivated; but the other ſorts may be admitted in a collection to encreaſe the variety. All of which may be had at moſt of the nurſeries; but the *Helianthus Tuberoſus* ſhould be but ſparingly admitted in compartments amongſt other plants, for its roots will multiply ſo greatly, as ſoon to over-run the ground.

The *Helianthus Tuberoſus* is by many eſteemed for its roots to eat, which is large, ſolid and fleſhy, ſomewhat reſembling a potatoe, and ſometimes as large, but much more knobbed and irregular, and greatly inferior to that root as an eſculent, it being rather of a watery and inſipid nature, though ſome are remarkably fond of them: they are commonly boiled and ſerved up with plenty of butter.

This ſort is commonly called Jeruſalem Artichoke, though with very little propriety, for the plant grows no where naturally about Jeruſalem, nor is it in the leaſt allied in any reſpect to *Cynara*, or Artichoke.

*Propagation, &c.*

The propagation of all the ſorts is very eaſy; the firſt ſpecies and varieties by ſeed, and all the others by roots.

The firſt ſpecies, therefore, and varieties, are raiſed from ſeed, ſowed annually in March or April, either in the borders, or other places where you deſign they ſhall flower, in patches, three or four ſeeds in each, about an inch deep, and when the plants are an inch or two high, thin out the worſt, leaving only one of the beſt plants in each patch; or ſow them thin in a bed or border, and when the plants are two or three inches high, tranſplant them, in moiſt weather, where they are finally to remain; or if you would bring them as forward into bloom as poſſible, the ſeed may be ſowed on a moderate hot-bed under a hand glaſs, giving plenty of air in mild weather, and plant them out in May.

The perennial kinds are propagated plentifully by dividing the roots, any time from October or November, till March: the four fibrous-rooted ſorts may be ſlipped into ſmall heads, and planted at once where they are to remain; they will flower the following ſummer, and will be increaſed greatly by autumn: and as to the tuberous-rooted kind, the large roots may either be divided into pieces, or plant the ſmall roots, every bit having an eye; they will readily grow, and multiply greatly in one year.

But when deſigned to raiſe the tuberous *Helianthus*, or Jeruſalem Artichoke as an eſculent, it ſhould be planted in an open ſpot of light ground in the kitchen garden. In ſpring having procured ſome large roots, they may be cut into four pieces; each making a ſet or plant; or, in default of large ones, may uſe ſmall ones whole. They are to be planted with a dibble, in rows three feet and a half aſunder, planting them four or five inches deep, and half a yard diſtance in each row; and, when planted, rake the ground even; and keep it clean from weeds by broad hoeing. The plants will come up in April or May, and ſhoot up into ſtalk ſix, or eight

feet

feet high, which in the end of July, or beginning of Auguſt, may be cut down half way, the better to admit the benefit of the air, rains, and dews to the roots to increaſe their bulk.

They will be fully grown by September, when ſome may be taken up for uſe; and about the end of that month, or in October, take them wholly out of the ground, and lay them in ſand in a dry place, for winter ſervice.

HELIOTROPIUM, *Heliotrope*, or *Turnſole*.

This genus compriſes a few herbaceous annuals, and ſome ſhrubby plants, all tender exotics; one of the latter is cultivated here as a green houſe ſhrub.

Claſs and order, *Pentrandria Monogynia*.

*Characters.*] CALIX is monophyllous, and five parted at top. COROLLA, is monopetalous, divided into five unequal parts. STAMINA, five filaments, and ſmall antheræ. PISTILLUM, four germina, ſlender ſtyle and notched ſtigma. PERICARPIUM, none, oval ſeeds lodged in the calix.

The ſpecies chiefly cultivated here is:

HELIOTROPIUM *Peruviana*.

*Peruvian Sweet-ſcented Heliotrope.*] Hath a ſhrubby ſtalk, branching numerouſly four or five feet high, ſpear-ſhaped, oval, rough, veined, hairy leaves, about three inches long, and one broad, placed ſparſedly; and from the ends of the branches, numerous cluſtered ſpikes of pale blue, ſweet-ſcented flowers, appearing great part of the year, and ſucceeded by ripe ſeeds in autumn.

This plant muſt be always kept in pots to move into the green-houſe in winter; and muſt be potted in any light rich garden-earth.

It is propagated eaſily by ſeed, and cuttings of its young ſhoots.

By Seed.—This ripens here: ſow it in pots of light earth in ſpring, and plunge them in a hot-bed; and when the plants are two or three inches high, plant them in ſeparate ſmall pots, plunging them alſo in a hot-bed to ſtrike; then inure them gradually to the full air.

By Cuttings.—Plant ſmall cuttings of the young ſhoots in ſpring or ſummer in pots, and if plunged in a moderate hot bed will ſooner take root.

HELLEBORUS, Black Hellebore, &c.

This genus retains a few hardy herbaceous perennials for ornament and medical purpoſes, obtaining in ſtature, ſome not more than three or four inches, others from one to two feet, adorned with many-lobed, and hand-ſhaped leaves, and pentapetalous flowers.

Claſs and order, *Polyandria Polygynia*.

*Characters.*] CALIX, none. COROLLA, five large roundiſh petals, and many ſmall nectaria placed circularly. STAMINA, numerous filaments, and compreſſed erect antheræ. PISTILLUM, ſeveral compreſſed germina, awl ſhaped ſtyles, and thick ſtigmas. PERICARPIUM, ſeveral bicarinated capſules, having the lower carinas ſhorteſt and the upper convex, and many round ſeeds.

This genus compriſes—The True Black Hellebore, or Chriſtmas Roſe—Winter Aconite——Wild Black Hellebore, or Bear's-foot, &c.

The ſpecies are:

[1]HELLEBORUS, *Niger*.

*True Black Hellebore, commonly called Chriſtmas Roſe.*] Helleborus with roots compoſed of many thick, fleſhy, ſpreading fibres, crowned by a large cluſter of lobed leaves, conſiſting each of ſeven or eight obtuſe, fleſhy lobes, united to one foot-ſtalk; and between the leaves ſeveral thick fleſhy flower-ſtalks three or four inches high, ſurmounted by large beautiful white flowers of five large roundiſh petals, and numerous filaments, appearing in winter, about, or ſoon after Chriſtmas.

This is the true black Hellebore of the ancients; the root is uſed in medicine, and is a ſtrong purgative.

[2]HELLEBORUS *Hyemalis*.

*Winter Aconite, formerly a ſpecies of Aconitum (Aconitum Hyemale).*] Hath a ſmall, bulbous, brown root, ſending up ſmall foot-ſtalks two inches high, each ſupporting one leaf, divided into many parts, and ſmall golden yellow flowers ſitting in the boſom of the leaves; appearing in January or February.

[3]HELLEBORUS *Foetidus*.

*Stinking Great Wild Black Helebore, or Bear's-foot.*] Hath large fibrous roots, upright ſmooth ſtalks dividing into buſhy heads, and branching two feet high, garniſhed with large pedated dark-green leaves of about nine long, narrow, ſerrated ſolioles, ending in acute points, and at the ends of all the branches numerous greeniſh flowers tipped with purple; appearing early in winter, and ſucceeded by plenty of ſeeds in the ſpring.

HELLEBORUS *Viridis.*

*Green-flowered Wild Black Hellebore, or Bear's foot.*] Hath thick fibrous roots, crowned with large digitate or fingered dark-green leaves, of nine long, narrow, ſerrated lobes; upright firm ſtalks a foot high, garniſhed with ſmaller leaves; and from the top many green flowers intermixed alſo with leaves: appearing in January and February, ſucceeded by plenty of ſeed in May.

All theſe four ſpecies are hardy herbaceous perennials, of which the third and fourth ſorts remain buſhy and green the year round, more particularly the third; and all the ſorts are ſo hardy as to ſucceed in any common ſoil of a garden: the firſt ſhould rather have a warm ſituation, but all the others will proſper any where; and the third and fourth either in an expoſed ſituation, or under the ſhade of trees; ſo are proper to mix in ſhrubberies and wilderneſs quarters.

The flowers of all the ſorts are compoſed of five roundiſh petals, and numerous filaments; thoſe of the *Helleborus Niger* are conſiderably the largeſt and moſt beautiful of all the ſorts.

All the ſpecies may be employed as plants of ornament to adorn the flower borders, and other parts of the pleaſure-ground.

They are cultivated by the nurſerymen for ſale, and their propagation and culture is very eaſy.

The firſt ſort, *Helleborus Niger*, poſſeſſes great merit, both for the ſingularity of its profuſion of bloom, in the midſt of winter, and for the great beauty of its flower; which being large, and bearing ſome reſemblance to a ſingle white roſe, and appearing often about Chriſtmas time, derived the appellation of Chriſtmas Roſe: it proſpers in the open borders, or may be planted in pots, to move when in bloom to adorn any particular place; obſerving it always flowers faireſt and the moſt abundantly in the front of a warm ſunny border. The plants may be tranſplanted, and the roots divided for propagation in autumn, i. e. September, October, or November; but the ſooner in autumn it is done, the ſtronger they will flower at their proper ſeaſon towards ſpring; or they may be removed in ſpring, after they have done flowering.

Its propagation is effected commonly by parting the roots; alſo by ſeed, when they ripen, which happens but ſeldom in this country.

But as being a fibrous-rooted perennial encreaſing in root, by off-ſets, or ſlips, its propagation is eaſily effected by dividing the root into ſlips in autumn, or in ſpring, after the flower is paſt, not too ſmall, planting them in a ſheltered border, and they will flower at their proper ſeaſon.

The ſecond ſort, *Helleborus Kyemalis*, or Winter Aconite, is eſteemed for its early bloom, which though a diminutive plant, almoſt the ſmalleſt of the bulbous-rooted tribe, yet it exhibits its golden flowers very ornamentally early in ſpring, when few others are to be ſeen; and is a very proper plant to adorn the edges of borders, and other flower compartments, in aſſemblage with ſnowdrops, &c. placing them in patches alternately, ſeveral roots in each patch; otherwiſe, as the plants being ſmall and near the ground, if not planted in cluſters, they will not make any conſiderable ſhew: plant, therefore, five or ſix roots at leaſt in each patch of four or five inches diameter, putting them two or three inches deep; where they may remain undiſturbed three years, or till encreaſed into large bunches, then taken up and ſeparated.

The roots being bulbous, they are tranſplanted when their leaves decay, from June till October, and they encreaſe faſt by off-ſets like other bulbs; which may be taken up and ſeparated every two, three, or four years, for propagation.

The third and fourth ſpecies being large, buſhy, ever-green, very hardy perennials, particularly the *Helleborus Foetidus*, flowering in the midſt of winter, and early in ſpring in any weather, effect a good variety at all ſeaſons; but although the flowers are not elegant, yet the plants appearing always green, of a robuſt aſpect, and flowering at a time of year when hardly any others appear in the open air, renders them proper ornaments for large borders, particularly in ſhrubbery and wilderneſs plantations, as they will proſper between ſhrubs, and under the ſhade of trees, &c. they being natives of woods in ſeveral parts of England, and may be raiſed in great plenty from ſeed; and from ſcattered or ſelf-ſown ſeeds many young plants will riſe.

They are alſo both medical plants, and for which uſe great quantities are raiſed in many gardens about London to ſupply the markets.

Both theſe ſorts are propagated by ſeed ſown as ſoon as ripe, or any time from March till

till September, though ſpring is the beſt ſeaſon. The ſeeds may be had of all the nurſery and ſeedſmen. Sow it in beds of common earth, and rake it in; and when the plants are three inches high, plant them out in beds a foot apart; and after having two or three months growth there, tranſplant thoſe intended for ornament where they are to remain; but thoſe raiſed for medical uſe, may remain in the beds.

Theſe plants may be removed either in ſpring or autumn, or even in winter, as they will readily riſe with balls about their roots.

HEMEROCALLIS, Day Lily, or Lily-Aſphodel.

Two herbaceous flowery perennials for the pleaſure-ground; producing very long, narrow, radical leaves, and naked annual ſtalks two feet high, adorned at top with large, liliaceous, ſix-parted, yellow and red flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, is an infundibuliforme campanulated petal, with a ſhort tube, and the limb deeply cut into ſix parts, which are ſpreading and reflexed. STAMINA, ſix awl-ſhaped declinated filaments, and long incumbent antheræ. PISTILLUM, a roundiſh ſulcated germen, filiforme ſtyle, and three-cornered ſtigma. PERICARPIUM, an oval, trigonal, trilobous, trilocular capſule, and numerous roundiſh ſeeds.

The *Liliaſtrum*, or St. Bruno's Lily, formerly of this genus, is removed to the genus *Anthericum*, its character determining it a ſpecies of that genus, ſee ANTHERICUM *Liliaſtrum.*

The ſpecies, therefore, now of this genus are:

1 HEMEROCALLIS *Flava.*

*Yellow Day Lily.*] Hemerocallis, with ſtrong fibrous roots, furniſhed with oblong yellowiſh tubers; ſending up keel-ſhaped hollow leaves two feet long; upright leafleſs firm ſtalks two feet high, dividing at top into ſeveral foot-ſtalks, each terminated by one large liliaceous yellow flower, of an agreeable odour.

*Variety.*] Small yellow Day Lily. (*Hemerocallis minor.*)

2 HEMEROCALLIS *Fulva.*

*Reddiſh, or Copper-coloured Day Lily.*] Hath roots compoſed of ſtrong fleſhy fibres, and large oblong tubers; radical, keel-ſhaped, hollowed, pointed leaves, a yard long, reflexed at top; and upright thick leafleſs ſtalks, three or four feet high, dividing at top into branches, terminated by large copper-coloured liliaceous flowers, having large long ſtamina, charged with fulvous coloured farina, which being touched or ſmelled to, is diſcharged in great plenty over the hands or face.

Both theſe ſpecies are very hardy, ſucceed any where, and multiply at a great rate by their ſpreading roots; which are perennial, but annual in leaf and ſtalk: they derive the name, Day Lily, from the diurnal duration of their flowers, and by being ſucceeded by new ones daily on the ſame plants for a fortnight or three weeks.

The flowers are of the Lily form, each of one petal, deeply cut into ſix parts. See the *Characters.*

They both flower in June, and ripen ſeeds in Auguſt.

Both the ſorts are proper furniture for large borders, and other compartments of the pleaſure-garden, and may be planted in autumn, or any time in open weather, from September till March.

Their propagation is effected abundantly by parting the roots, for they increaſe greatly by off-ſets, which may be divided in autumn, or almoſt any time after flowering, or before they begin to ſhoot in ſpring; and each ſlip will flower at the proper ſeaſon.

They may alſo be raiſed from ſeed, ſown ſoon after they are ripe, in a bed of common earth, and raked in: the plants will come up in ſpring following; prick them out in nurſery beds in ſummer, and ſome of the ſtrongeſt will flower the ſecond year.

HEPATICA, Noble Liverwort, now a ſpecies of *Anemone.* See ANEMONE *Hepatica.*

HERBA, an Herb All vegetables which riſe with leaves and ſtalks annually from the root, without becoming woody and durable, are properly conſidered as Herbs; ſuch, for inſtance, are many of the kitchen-garden eſculents, and medical plants; and a vaſt train of the ornamental or flowery tribe may alſo come under that denomination. See HERBACEOUS PLANTS.

But many of the underſhrubby eſculent and medical plants are alſo ſometimes conſidered as Herbs; ſuch as ſage, thyme, rue, hyſſop, winter-ſavory, lavender, &c. but theſe having ligneous, durable ſtalks and branches, are more allied to the ſhrubby tribe, ſo are properly of the under-ſhrubby kind. See SUFFRUTICOSUS.

HERBACEA *Planta.* Herbaceous plants, or vegetables of an herb-like nature.

All vegetables that produce leaves and ſtalks annually from the root, and whoſe ſtalk or ſtems remain green and ſucculent, or ſoft, not becoming woody, nor durable, but die down to the root every year, ſoon after they have produced flowers, &c. are properly Herbaceous Plants; and of which there are annuals, biennials, and perennials. Annuals are ſuch which periſh, ſtem, root and all, at the end of the year; biennials ſubſiſt two years, generally periſhing as ſoon as they have flowered; perennials are perpetuated by their roots producing new ſtems every year for the purpoſe of producing flowers and ſeed.

So that Herbaceous vegetables are very diſtinguiſhable from the woody kinds, ſuch as trees, ſhrubs, and under-ſhrubs, whoſe ſtems and branches are woody or ligneous, and durable; and the ſtalks of the Herbaceous tribe periſh annually, or at leaſt as ſoon as they have flowered, and perfected their ſeeds, and the ſame individul ſtalk never lives to flower again, but dies in autumn; and in annuals, and biennials, root and all; but perennials ſurviving by the root, ſend up freſh ſtalks in ſpring.

Of the Herbaceous tribe are moſt of the eſculents of the kitchen-garden, except thoſe of the under-ſhrubby kinds, ſuch as ſage, thyme, hyſſop, &c. vaſt numbers of the medical plants are alſo Herbaceous; and of the flowery kinds for the pleaſure-garden, almoſt all the annuals and biennials are herbaceous; as alſo all the perennials, both the fibrous, bulbous, and tuberous-rooted kinds, whoſe ſtalks decay annually, are likewiſe Herbaceous Plants. Therefore Herbaceous Plants compoſe a very conſiderable part of the vegetable creation.

HERMANNIA, *Hermannia.*

This genus conſiſts of ſhrubby exotics for the green-houſe, growing from about half a yard to ſix or ſeven feet high, adorned principally with ſmalliſh ſimple foliage, and quinquepetalous flowers, in numerous ſpikes.

Claſs and order, *Monadelphia Pentandria.*

*Characters.*] CALIX, is monophyllous, five-parted at the brim, inflexed and permanent. COROLLA, five petals ſpirally twiſted contrary to the apparent motion of the ſun, broad and ſpreading above. STAMINA, five monadelphous filaments, and acuminated conniveut antheræ. PISTILLUM, a roundiſh pentangular germen, awl ſhaped ſtyle, and ſimple ſtigma. PERICARPIUM, a roundiſh five-cornered quinquelocular capſule, and many ſmall ſeeds.

The ſpecies that are principally cultivated are:

[1]HERMANIA *Lavendulifolia.*

*Lavender-leaved Hermannia* ] Hath a ſhrubby ſtalk and ſlender branches, very buſhy, about a foot and a half high; ſmall, ſpear ſhaped, obtuſe, hairy leaves, and cluſters of ſmall yellow flowers along the ſides of the branches, from June till autumn.

[2]HERMANNIA *Althæifolia.*

*Althæa-leaved Hermannia.*] Hath a ſhrubby ſtalk, and ſoft woolly branches, growing two feet high, ovaliſh, plaited, crenated, woolly leaves, and numerous yellow flowers, in looſe ſpikes at the ends of the branches, in June and July.

[3]HERMANNIA *Groſſularifolia.*

*Gooſeberry-leaved Hermannia* ] Hath a ſhrubby ſtalk and ſpreading branches, growing three or four feet high; ſpear ſhaped, pinnatifid, ſmall, cloſe-ſitting leaves, and bright yellow flowers, by twos on each foot-ſtalk, numerouſly at the ends of all the ſhoots and branches, in April or May.

[4]HERMANNIA *Alnifolia.*

*Alder-leaved Hermannia.*] Hath a ſhrubby ſtalk and branches, growing irregularly four or five feet high; wedge-ſhaped, plaited, crenated leaves; and pale yellow flowers in ſhort ſpikes from the ſides and ends of the branches, in April and May.

[5]HERMANNIA *Hyſſopifolia.*

*Hyſſop-leaved Hermannia* ] Hath a ſhrubby upright ſtalk branching, out laterally, ſix or ſeven feet high; ſmalliſh, ſpear-ſhaped, obtuſe, ſerrated leaves; and pale yellow flowers in cluſters from the ſides of the branches, in May and June.

All theſe five ſpecies are African ſhrubs, but ſucceed here with the protection of a green-houſe in winter, ſo muſt be potted in pots of rich garden mould, and managed as other green-houſe ſhrubs. See GREEN-HOUSE PLANTS.

They are ever green, and moſtly of buſhy growth, and produce a vaſt profuſion of flowers in April, May, and June.

The propagation of all the ſorts is by cuttings of their young ſhoots, any time from April till July, planted in pots of rich earth, which if plunged in a moderate hot bed, they will ſoon ſtrike; and thoſe planted in ſummer will alſo ſtrike without the aid of hot-beds, even in

in beds of common earth, watered and ſhaded occaſionally; and when rooted and begin to ſhoot, tranſplant them each into a ſmall pot.

They may alſo be raiſed from ſeeds; but this is ſeldom produced good here; it is procured from abroad, and muſt be ſowed in pots, and placed in a hot-bed.

HERMAPHRODITUS *Flos.* Hermaphrodite Flower. A flower furniſhed with both the male and female organs of generation, i e. the filaments and antheræ, the male organs; and the germen, ſtyle, and ſtigma, as the female; all of which being contained within the ſame calix and corolla, as in moſt, they are denominated Hermaphrodite Flowers.

Of this kind of flower, are thoſe of all the claſſes, except *Monoecia* and *Dioecia*; in the former of which, male and female flowers, having each its diſtinct parts, are produced ſeparate on the ſame plant; in the latter on diſtinct plants; and in the claſs *Polygamia*, there are always Hermaphrodites mixed with the males, or females, or both, either on the ſame, or ſeparate plants; and in the claſs *Syngeneſia*, which comprehends the numerous tribe of compound-flowers, and in which ſometimes the flower is compoſed entirely of Hermaphrodite florets, and ſometimes Hermaphrodite and females, and frequently Hermaphrodites and florets of no ſex or neuter. See CLASSIS.

So that the greateſt part of the vegetable creation produces Hermaphrodite flowers, either wholly, or mixed with males, or females, or both; whereby Hermaphrodites are as frequent in the vegetable, as they are rare and unuſual in the animal kingdom.

Therefore remarking, that all flowers, whether ſimple, or compoſed of many florets, having both male and female organs within the ſame corolla, either ſimple, as above ſaid, or in the corollula, or florets of a compound flower, are by botaniſts denominated Hermaphrodites, to diſtinguiſh them from males and females, which have each their parts diſtinct in their reſpective corolla.

And all plants producing Hermaphrodite Flowers only, are termed Hermaphrodite plants.

HERNANDIA, Jack-in-a-box Tree:

It compriſes two ever-green exotic trees of the Indies, ſometimes retained here in ſtoves for variety, adorned with very large beautiful ſimple foliage.

Claſs and order, *Monoecia Triandria.*

*Characters.*] CALIX, male and female flowers, having a partial involucrum of four oval leaves, and each of the females a bell-ſhaped cup. COROLLA, is of ſix petals in the males, and eight in the females. STAMINA, three filaments, and large oblong erect antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and large half-funnel-ſhaped ſtigma. PERICARPIUM, the calix becomes a large roundiſh, ſwollen, hollow fruit, incloſing a hard drupaceous juiceleſs nut.

The ſpecies are:

[1]HERNANDIA *Sonora.*

*Sonorous Hernandia, commonly called Jack-in-a-box.*] Grows twenty or thirty feet high, garniſhed with large broad peltated leaves, and monoecious flowers, ſucceeded by a large ſwollen, hollow fruit, formed of the calix, having a hole, or open at the end, and a hard nut within; and the wind blowing into the cavity of the fruit, makes a very ſonorous whiſtling and rattling noiſe: hence the tree derived the name, Jack-in-a-box.

[2]HERNANDIA *Ovigera.*

*Oriental oval-leaved Hernandia.*] Grows many feet high, garniſhed with large oval leaves, not peltated; and monoecious flowers, ſucceeded by ſwollen fruit, open at the end, and a nut within.

Both theſe exotics are of the tree kind, natives of the Eaſt and Weſt Indies, where they attain a large growth; but here, being kept in ſtoves, they rarely grow higher than common ſhrubs, and very few, if any, of them have flowered or fruited.

They requiring a hot-houſe here, muſt be potted in pots of rich light earth, and always retained in that conſervatory.

Their propagation is by ſeed, i. e. their nuts procured from the Weſt Indies; ſowing them in pots of rich earth, and plunge them in the bark hot-bed; and when the plants come up, prick them out into ſeparate pots, plunging them alſo in the bark-bed.

HESPERIS, Rocket, Dame's Violet, or Queen's Gilliflower.

The plants are hardy herbaceous biennials and perennials, cultivated as flowery plants, producing annual ſtalks, two feet high, ſimple leaves, and tetrapetalous cruciforme flowers, in large ſpikes at top, ſome of which are of great fragrance.

Claſs and order, *Tetradynamia Siliquoſa.*

*Characters.*] CALIX, is four leaved and deciduous. COROLLA, four oblong cruci-

forme.

forme petals. STAMINA, four long and two ſhort filaments, and narrow erect antheræ. PISTILLUM, a four-cornered germen, no ſtyle, but an oblong ſtigma ſitting on the germen. PERICARPIUM, a long compreſſed plane, bilocular pod, and many oval ſeeds.

The moſt material ſpecies are;

[1]HESPERIS *Matronalis.*

*Dame's Violet, or Common Sweet-ſcented Garden Rocket.*] Hath fibrous roots, crowned by a tuft of long ſpear-ſhaped rough leaves; upright, ſingle, hairy ſtalks, two feet high; garniſhed with oval, lanceolate, ſlightly indented, cloſe-ſitting leaves; and the ſtalk and branches terminated by large, long ſpikes of ſweet-ſcented flowers, of different colours and properties in the varieties.

*Varieties of this are;*] Garden Rocket, with ſingle white flowers—double white flowers—ſingle and double purple flowers—purple and white flowers—crimſon flowers. All of which are ſo remarkable for imparting a moſt fragrant odour, that the ladies were fond of having them in their apartments. Hence derived the name Dame's Violet, and bearing ſome reſemblance to a ſtock-gilliflower, were ſometimes alſo called Queen's-gilliflower; but are now moſt commonly called Rocket.

[2]HESPERIS *Inodora.*

*Scentleſs Rocket.*] Hath fibrous roots, upright round firm ſtalks, two feet high, garniſhed with ſpear-ſhaped, acute-pointed, ſharply indented, cloſe fitting leaves, and all the branches terminated by large ſpikes of ſcentleſs flowers, with obtuſe petals; of different colours and properties in the varieties.

*Varieties.*] Scentleſs Rocket, with ſingle white flowers—double white flowers—ſingle and double purple flowers. All of which are devoid of ſcent, but are ſhowy garden flowers.

[3]HESPERIS *Triſtis.*

*Dull-flowered Night-ſmelling Rocket.*] Hath fibrous roots; upright, branching ſpreading, briſtly ſtalks, two feet high; ſpear-ſhaped, pointed leaves; and ſpikes of pale purple flowers, of great fragrance in the evening.

They are all fibrous-rooted plants, the roots crowned with a large tuft of long leaves, and produce their flower-ſtalks annually in ſpring, flower in ſummer, ripen ſeeds in autumn, and die to the root ſoon after.

All the three ſpecies may be deemed both biennial and perennial; for, conſidered as biennials, they being raiſed one year from ſeed, flower the next, and then frequently periſh root and all, eſpecially the ſingles; but, with ſome care, both they and the doubles may be continued ſome years: and conſidered as perennials; for by cutting down ſome of their flower-ſtalks as ſoon as the flowers begin to fade, or rather before they attain a flowering ſtate, it often promotes their forming off-ſets at bottom the ſame ſeaſon for encreaſe, which being ſeparated early in autumn, each forms a plant for next year's bloom; and is worth practice for all the double kinds; by which means the plants may ſometimes be continued from year to year, otherwiſe they are rather naturally of the biennial kind; and it is, therefore, alſo proper to raiſe ſome annually from ſeeds, as directed in their propagation.

They are all hardy, more eſpecially the firſt and ſecond ſpecies, which proſper in any of the open borders, and in any common ſoil of a garden; but the third ſort being rather impatient of ſevere froſt, and much moiſture in winter, ſhould have a dry warm ſituation; and place a few in pots to move to the ſhelter of a frame in inclement weather.

The flowers of all the ſorts are formed ſeparately of four cruciforme petals, which being numerous, and collected into large ſpikes, make a fine appearance, but more particularly the double varieties, which being as large and full of petals as double ſtock-gilliflowers, are exceedingly beautiful garden flowers.

They all flower in June and July, and ripen abundance of ſeed in Auguſt.

Their ſtalks always decay in autumn, ſoon after the ſeed are ripe.

All the ſorts are very ornamental furniture for any of the open borders of the pleaſure-ground, and to interſperſe in aſſemblages with herbaceous plants, towards the fronts of the moſt conſpicuous ſhrubbery clumps, contiguous to lawns and grand walks.

They may be planted out in autumn, or early in ſpring, before they advance much for flowering; and with care they may be removed with balls to their roots, ſo as ſcarce to feel their removal

### *Propagation.*

Their propagation is performed three different ways: by ſeeds, by off-ſets of the roots, and by cutttings of the flower ſtalk.

By

By Seed.—This is ſold very cheap at all the nurſeries, and March and April is the ſeaſon for ſowing it; which ſow in a bed or border of light earth, and either rake it in lightly, or cover it a quarter of an inch deep with light mould; and when the plants are come up three or four inches high, plant them out in beds ſix inches apart, to remain till October or ſpring following; then tranſplant them where you deſign they ſhall flower, which they will all effect the enſuing ſummer.

Obſerve, moſt of theſe ſeedlings will come ſingle, that is, produce ſingle flowers, and many of theſe go off after they have flowered; but as they may be eaſily raiſed in any quantity from ſeed as above, it is proper to raiſe a freſh ſupply annually to diſperſe in the common borders.

But as to the doubles, they are propagated with certainty only by dividing the roots, or by cuttings, as directed below.

By Dividing the Roots.—This, and the cuttings of the flower-ſtalks, are the only methods to propagate the double kinds, for doubles of them are but very ſparingly obtained from ſeed; and as they are rather ſparing in forming off-ſets from the root for propagation, as before obſerved, unleſs aſſiſted by art, and being likewiſe often apt to decay entirely, root and all, after they have flowered, as being ſomewhat of a biennial nature, without practiſing a particular experiment to promote young off-ſets from the root; therefore let ſome good plants be ſet apart in any open bed or border for propagation, not ſuffering them to run up fully to flower; but when their flower-ſtalks have advanced about eight or ten inches high, cut them down cloſe to the ground, and according as they ſhoot again, cut them alſo off; and by thus ſtopping their upright growth, the roots will more readily throw out young off-ſets from their ſides all around, which will be well formed by Auguſt, or early in September, when the whole root ſhould be taken up, and the off-ſets divided ſeparately, and planted in a nurſery-bed, ſix inches diſtance, to remain till October, or ſpring following, then removed with balls to where they are to ſtand to flower; the flower-ſtalks which are occaſionally cut down to promote encreaſe of off-ſets at bottom, may be divided into lengths, and planted as hereunder directed; each cutting will root and form a plant for next year's bloom.

The above practice ſhould be purſued annually to keep up your ſtock of doubles, for thoſe which ſhoot up to full growth and bloom, rarely put out any off-ſets, unleſs the ſtalks are cut down as ſoon as the flowers begin to fade, when ſometimes they emit a few, but which will not be ſo many, nor ſo ſtrong as by the other method.

By Cuttings of the Flower ſtalks.—Having directed above to cut down the flower-ſtalks, when about half grown; each of theſe may be divided into two, ſo as to make two cuttings, though the lower half as being more hardened, will form the beſt cutting of the two; they may, however, both be planted to take their chance. Having procured a quantity of theſe kind of cuttings, from about three to five inches long, plant them in a ſhady border, putting them two parts out of three into the ground, about three inches aſunder, and give water; let the watering be frequently repeated, and many of the cuttings will be well rooted, and form ſhoots at top in ſix or eight weeks: but to promote their rooting more effectually, they may be covered cloſe with hand or bell-glaſſes, as ſoon as planted, whereby they will ſtrike much ſooner; obſerving when they begin to ſhoot at top, to raiſe the glaſſes to admit air, to which harden them fully by degrees.

Sometimes cuttings of the flower-ſtalks of thoſe which have flowered, cut down as ſoon as the flower begins to fade, and divided into lengths, and planted as above, will alſo grow, though they will not produce ſo good plants as thoſe formed of the young ſtalks early in the ſummer.

HIBISCUS, Syrian Mallow, or *Althæa Frutex*, &c.

This genus furniſhes a hardy, deciduous, flowering ſhrub, and flowery annual for the pleaſure ground, and ſome ſhrubby and herbaceous exotics for the hot-houſe, adorned moſtly with largiſh ſimple, lobated foliage, and large quinquepetalous mallow-ſhaped flowers.

Claſs and order, *Monadelphia Polyandria*.

*Characters.*] CALIX, is double, the outer ſeries is of many narrow permanent leaves, and the interior of one leaf five-parted at the brim. COROLLA, five heart-ſhaped petals united at their baſe. STAMINA, numerous filaments that coaleſce below, and form a column, and kidney-ſhaped antheræ. PISTILLUM, a roundiſh germen, and ſlender ſtyle, five-parted at top, each part having a capitated

capitated ſtigma. PERICARPIUM, a quinquevalvular, quinquelocular capſule, and kidney-ſhaped ſeeds.

There are many ſpecies of this genus, but not more than four or five commonly cultivated in the Engliſh gardens; of which ſome are hardy, and others ſo tender as to require a ſtove in this country.

*Hardy Kinds.*

[1]HIBISCUS *Syriaca.*

*Syrian Hibiſcus, commonly called Althæa Frutex.*] Hath a ſhrubby ſtem and branches, forming a buſhy head, five or ſix feet high; garniſhed with oval, wedge-ſhaped, alternate leaves, cut at top into three indented lobes; and from the ſides of all the young ſhoots, numerous, large, pentapetalous, ſpreading flowers, of different colours in the varieties, having all dark middles, darting out each way in radiant directions towards the extremity of each petal.

*Varieties of this are;*] *Althæa Frutex* with white flowers—with red flowers—pale purple flowers—deep purple flowers—with yellow flowers—and with variegated flowers, called Painted Lady *Althæa Frutex*—likewiſe with ſilver-ſtriped leaves—gold-bloached leaves.

All theſe varieties are ſhrubby, flower in Auguſt, producing ſuch great quantities of flowers in daily ſucceſſion for three or four weeks, that the ſhrubs appear covered therewith, making a moſt delightful appearance, and are the greateſt ornaments of the autumn ſeaſon, of almoſt any of the ſhrubby tribe.

[2]HIBISCUS *Trionum.*

*Trionum, Bladder Ketmia, Venice Mallow, or Flower of an Hour.*] Hath an herbaceous branchy ſtalk, growing a foot and a half high; garniſhed with three-lobed leaves, deeply jagged on the edges into oppoſite obtuſe ſegments; and from the joints of the ſtalks yellowiſh flowers with dark-purple bottoms, having the inner cup ſwollen like a bladder: hence the name, Bladder Ketmia.

This ſpecies is annual, ſometimes called Flower of an Hour, (*Flos Hora*) from the ſhort duration of its flowers, which in hot dry weather they but juſt open, and wither away in an hour or two; but theſe are ſucceeded by a plentiful daily ſucceſſion for a long time.

*Tender Kinds.*

[3]HIBISCUS *Mutabilis.*

*Changeable-flowered Hibiſcus, commonly called China Roſe.*] Hath a ſhrubby, ſoft, ſpongey ſtem, branching into a ſpreading head, riſing ten or twelve feet high; adorned with heart-ſhaped, five-angled, ſerrated, ſhining-green leaves, but pale underneath; and from the axillas of the ſtalk and branchs, large, pentapetalous, ſpreading flowers, appearing firſt white, gradually changing to a bluſh-red colour, and from that to a purple,

[4]HIBISCUS, *Roſa Sinenſis.*

*Roſe of China, or Double China Roſe.*] Hath a ſhrubby tree-like ſtem, dividing into a ſpreading head, riſing twelve or fourteen feet high; oval, acuminated, ſerrated leaves; and from the ſides of the branches, large red flowers, having many oblong roundiſh petals in ſeveral ſeries, like a large double roſe; and are exceedingly elegant, which, by way of pre-eminence, is by botaniſts called, the *Roſe of China* (*Roſa Sinenſis.*)

[5]HIBISCUS *Malvaviſcus.*

*Viſcous Mallow, with ſcarlet flowers.*] Hath a ſhrubby ſtalk, branching ten or twelve feet high; heart-ſhaped, angular, crenated leaves; and from the wings of the ſtalks ſcarlet flowers, with the petals twiſted together; ſucceeded by roundiſh beautiful ſcarlet berries of a viſcous, or clammy nature.

The flowers of all theſe ſpecies of Hibiſcus, conſiſt of five largiſh heart ſhaped petals, and numerous ſtamina, forming a column below (ſee the *Characters*); and in moſt of the ſorts the flowers are numerous and very ornamental.

Thoſe, of all the ſorts, are but of ſhort duration, but are ſucceeded in moſt by new ones daily.

The *Hibiſcus Syriacus*, commonly known by the name of Althæa Frutex, is originally of Syria, but ſo hardy that it will grow here almoſt any where in an open ſituation; and is ſo ornamental when in bloom, that all the varieties merit admittance into every ſhrubbery in the moſt conſpicuous point of view, where the different varieties will have a moſt beautiful effect.

Their propogation is by ſeed, by layers, and by cuttings.

By Seed.—This is procured from abroad by the ſeedſmen; and March and April is the ſeaſon for ſowing it, which may either be ſown in pots, and plunged into a ſlender hot-bed to forward them, or may ſow them in a bed of light earth in a warm ſituation, covering it half an inch deep; the plants will ſoon come up, giving water in ſummer, and a little ſhelter in ſevere froſts; and when two years old plant them out in nurſery rows.

By Layers.—Autumn is the proper time; give the ſhoots a little cut through the bark at one or two joints, and lay them in the

uſual way: they will be rooted in one year.

By Cuttings.—March and April is the time to plant them: chooſe young ſhoots, which if planted in pots and plunged into a hot bed, will more readily ſtrike; though if planted in a ſhady border, many of them will alſo put out roots.

The ſecond ſort, commonly called Bladder Ketmia, is a hardy annual of the flowery kind, and merits a place in the collection of hardy annuals in the open borders, &c.

Its propagation is by ſeed, which may be ſowed either in autumn or ſpring, in the place where you deſign the plants ſhall flower, in patches, ſeveral ſeeds in each; leaving, however, but two or three of the beſt plants in each patch.

The three tender ſpecies being all natives of China, require to be continued moſtly in a ſtove in this country; the firſt two of them produce flowers of the moſt ſingular beauty and elegance, equalling moſt of our fineſt roſes, and both of which flower in great perfection in our ſtoves; and in Aſia, their native ſoil, are ſome of their fineſt flowers: we often ſee them painted in many of the Chineſe pieces, as alſo on the porcelain ware, to embelliſh china bowls, and other china veſſels, particularly the flower of the *Hibiſcus Mutabilis*.

However, as all the three ſpecies will flower beautifully here, and ſometimes perfect ſeeds, they are worth the attention of thoſe accommodated with hot-houſes; keeping them always in pots of rich earth, and retaining them conſtantly in that department; for although they will ſucceed in the open air in the heat of ſummer, and in a good greenhouſe in winter, yet rarely flower well without the continual ſhelter of the ſtove.

The propagation of theſe three tender kinds are effected by ſeed, and ſometimes by cuttings.

By Seed.—March, April, or May, is the time to ſow it, and ſhould have the aid of a hot-bed: ſow it, therefore, in pots of rich earth, half an inch deep, and plunge them in any hot-bed under glaſſes, or in the bark-bed in the ſtove; and when the plants are two or three inches high, plant them out in ſeparate ſmall pots, give water, and plunge them alſo in the hot-bed.

By Cuttings.—Plant ſhort cuttings of the young ſhoots in pots, in ſpring or ſummer, and plunge them in the bark-bed.

HIERACIUM Hawkweed.

The plants are hardy herbaceous perennials; one of which is retained as a flowery plant, has oval leaves, and annual ſtalks a foot high, ſurmounted by compound-flowers in a corymbus.

Claſs and order, *Syngeneſia Polygamia Æqualis*.

*Characters.*] CALIX, many narrow unequal leaves. COROLLA, many hermaphrodite ligulated florets, in one general cup, each five parted at the top. STAMINA, five filaments and cylindric antheræ. PISTILLUM, an oval germen, ſlender ſtyle, and two recurved ſtigma. PERICARPIUM, none. SEMINA, a four cornered ſeed to each floret, crowned with down, ſitting in the calix.

There are many ſpecies, but not more than one uſually cultivated, viz.

HIERACIUM *Aurantiacum*.

*Orange coloured Garden Hieracium, ſometimes called Grim the Collier*] Hieracium with many oblong oval, entire leaves, crowning the root; an upright, ſingle, hairy, almoſt leafleſs ſtalk, a foot high, terminated by reddiſh orange-coloured flowers, in a corymbus, having dark coal-aſh-coloured calices, whence the cant name, Grim the Collier.

This is a hardy perennial, with fibrous durable roots, but annual ſtalks, which riſe in ſpring, flower in June, continuing in ſucceſſion two or three months, ripen ſeeds in autumn, and the ſtalks ſoon after decay.

It is proper furniture for the fronts of any of the compartments of the pleaſure garden.

Its propagation is by ſeed, and by parting the roots. Sow the ſeed in autumn or ſpring, in a bed or border, and rake them in; and in June, when the plants are two or three inches high, prick them out in beds to remain till autumn; then tranſplant them where they are to remain.

By parting the Roots.—In autumn or ſpring divide the roots into ſlips or off ſets, and plant them where they are to flower.

HIPPOPHAE, Sea Buckthorn.

Of this genus there are two hardy deciduous ſhrubs for the ſhrubbery, adorned with ſpear-ſhaped and oval entire leaves, and male and female apetalous flowers.

Claſs and order, *Dioecia Tetandria*.

*Characters*] CALIX, male and female flowers on different plants, having monophyllous two-parted cups. COROLLA, none. STAMINA, four ſhort filaments, and oblong

angular antheræ. PISTILLUM, a roundiſh germen, ſhort ſtyle, and thick erect ſtigma. PERICARPIUM, a globular unilocular berry, and one ſeed.

The ſpecies are;

[1]HIPPOPHAE *Rhamnoides.*

*Rhamnoides, or European Willow-leaved Sea-Buckthorn.*] Hippophae with a ſhrubby ſtem, branching irregularly eight or ten feet high, having a dark brown bark, and armed with a few thorns; ſpear-ſhaped, long, narrow, ſeſſil leaves, of a dark-green above, and hoary underneath; and male flowers in ſmall cluſters, and females on ſeparate plants, growing ſingly, ſucceeded by berries in autumn.

[2]HIPPOPHAE *Canadenſis.*

*Canada oval-leaved Sea Buckthorn.*] Hath a ſhrubby brown ſtem branching eight or ten feet high; oval leaves, and male and female flowers on ſeparate plants.

Both theſe ſhrubs are very hardy, the firſt grows wild on the ſea-ſhores in ſeveral parts of England, and the ſecond in America.

They are retained in gardens as furniture for the ſhrubbery to encreaſe the variety with their two-coloured leaves, being of a dark green above, and of a hoary white underneath; and in winter, when devoid of foliage, their young ſhoots being covered with turgid, irregular, ſcaly buds, exhibit alſo a ſingular variety.

They are cultivated in all the nurſeries for ſale; and may be tranſplanted any time in open weather from October till March.

Both ſorts are propagated abundantly by ſuckers from the root, by layers, and by cuttings of their young ſhoots. All of which may be performed in autumn, winter, or ſpring.

HOE, for hoeing ground, &c.

A Hoe is a moſt uſeful and well known garden inſtrument, of which there are two principal ſorts: a Drawing-hoe, and a Scuffling-hoe. The former of which is, however, of the moſt general uſe.

Drawing-hoe.—This is the moſt common and uſeful kind of Hoe for moſt ſorts of hoeing work: which being fixed with its edge inward, the workman in uſing it, always draws towards him, and is one of the moſt uſeful implements of gardening for many purpoſes: ſuch as drawing drills for ſowing many ſorts of ſeeds and roots; for looſening the earth about, and moulding up the ſhanks of plants; and hoeing down weeds between all ſorts of plants, that ſtand diſtant enough to admit it; and is the beſt adapted Hoe for thinning out eſculents to proper diſtances to acquire their proper growth, ſuch as onions, carrots, parſneps, turneps, ſpinach, &c. by cutting up all the ſuperfluous plants, or ſuch that grow too cloſe, and at the ſame time cuts up all weeds, as well as looſens the earth effectually about the remaining plants; which always proves very beneficial culture to all vegetables.

But of the Drawing-hoe kind, there ſhould be three or four different ſizes, from ſix or eight inches width, down to an inch and a half, as deſcribed below.

Firſt ſize.—This is a large Hoe for common uſe, about ſix or eight inches by four broad, fixed on a long handle for both hands, and is the proper ſort to uſe for all common hoeing-work; ſuch as drawing drills for ſowing peas, beans, kidney-beans, &c. (ſee DRILL SOWING) and is the moſt eligible ſized Hoe for hoeing between rows of all thoſe kinds of plants, and all others that ſtand diſtant enough either in rows, or otherwiſe, for the hoe to paſs between them, both to cut down all weeds and looſen the ground, and to earth up the ſtems of the plants. It is alſo the proper ſized Hoe for hoeing turneps, eſpecially the general crops of the larger kinds, to thin them out to proper diſtances, and cut down weeds; likewiſe for all other purpoſes of hoeing where the plants ſtand diſtant, both in the kitchen and pleaſure-garden: and this is the proper ſized Hoe for general uſe.

Second ſize.—This ſhould be about four inches broad, and is uſeful for hoeing among various plants, where the former ſort of Hoe cannot be commodiouſly employed, and to thin ſuch eſculent crops that require but moderate diſtances; ſuch as the ſmall early Dutch turneps for the firſt crop; alſo for the general crop of carrots, parſneps, ſpinach, &c. this is alſo a proper ſized Hoe for hoeing flower-beds and borders, where the plants ſtand cloſe.

Third Size.—This ſhould be two inches and a half, but not more than three inches broad, fixed on a ſhort handle to uſe with one hand; and is for the purpoſe of ſmall-hoeing onions, to cut them out the full diſtance they require to grow to their proper ſize. Likewiſe for early crops of carrots, ſpinach, &c. and is a very convenient ſized Hoe for hoeing between many other young

or ſmall plants where a larger Hoe cannot be readily admitted.

Fourth Size.—This ſhould be but an inch and a half broad, fixed on a ſmall ſhort handle for one hand, and is of a proper ſize for ſmall-hoeing onions the firſt time, where they ſtand pretty cloſe, and where it is not deſigned to thin them out at once to their full diſtance, but to leave them rather thickiſh for culling, &c. and will be found very convenient for occaſional uſe among many ſmall crops.

Each of the above ſizes of drawing-hoes will be found extremely uſeful in their turns; and every gardener ſhould furniſh himſelf with a proper ſet, as the expence is but trifling, and are ſold by moſt of the nurſerymen, and at all the ironmongers ſhops.

Always keep the edges of the Hoes ſharp by occaſional grinding on a grind-ſtone, that they may cut clean at every ſtroke, and the work will be both more eaſily, effectually, and expeditiouſly performed.

Scuffling-hoe.—This is commonly called a Dutch Hoe, as being much uſed in Holland for ſcuffling their ſand-walks, &c. it is fixed with the edge outward, on the end of a long handle, ſo as the perſon uſing it, puſhes it from him, and goes backward, never treading on the hoed ground, as with the drawing hoe; and as to ſize, is from about four to ſix or eight inches wide, open in the middle, for the mould and weeds to paſs through, ſo as not to be drawn in heaps; having a long ſocket at the back part, in which to fix the handle, which may be five or ſix feet long.

This Hoe is very proper for ſcuffling over any piece of ground to deſtroy weeds that is clear from crops, or between crops that ſtand wide, and in which a perſon may make conſiderably more expeditious work than with a Drawing-hoe, eſpecially when the weeds are not ſuffered to grow large; in which caſe one man can do as much as two. Obſerving, however, this Hoe is adapted principally for cutting down weeds, or ſtirring the ground between wide crops, as above noticed; but not proper for hoeing out crops of eſculents, nor for earthing up the ſhanks of plants, nor for hoeing where the plants ſtand cloſe.

This Hoe for cutting down weeds will alſo make great riddance in ſhrubberies and wilderneſs quarters, where the ſhrubs ſtand diſtant from one another.

It is alſo one of the beſt ſorts of Hoes for ſcuffling over ſand-walks, or others of looſe materials, to deſtroy weeds, moſs, &c.

This kind of hoe will alſo be found very uſeful to run over flower borders, to cut up ſtraggling weeds; which, being fixed on a long handle, may be effected by ſtanding in the walks, without treading on the borders.

It may be had at all the nurſeries, and at the ironmongers.

HOEING, a neceſſary garden culture performed by hoe, to deſtroy weeds, looſen the ſoil, and to mould up the ſhanks of plants.

Hoeing is the moſt expeditious method of deſtroying weeds between all plants that ſtand diſtant enough to admit the hoe between: obſerving, that all Hoeing deſigned principally to deſtroy weeds, ſhould always be performed in dry weather, and the more ſunny the better, eſpecially when the weeds are not to be raked off, that they may die as they are cut down, or at leaſt be ſo much flagged or withered by the ſun as not to grow again; cut deep enough to cut the weeds nearly up by the roots, which may be eaſily effected to all the annuals, or ſeed-weeds; for if they are only ſtumped off, they will ſoon ſhoot out again; obſerve alſo in the courſe of Hoeing, not to draw the earth and weeds in heaps, as often done, as the weeds, if not raked off, will often grow again; let, therefore, the work of Hoeing be always performed ſo evenly, that all the weeds be turned upon the ſurface clear out of the mould; and if any are unavoidably drawn in heaps, or the earth adhere much about the weeds ſo cut up, always diſperſe them by a ſtroke of the Hoe, that all the weeds may be turned fairly above the ground for the ſun and air to kill them.

The above work of Hoeing down weeds, is performed either by a Drawing or Scuffling-hoe, as may be convenient, according to the hints given under the article Hoe.

But Hoeing, beſides its uſe in expeditiouſly deſtroying the weeds, it at the ſame time, by looſening the ſurface, diſpoſes the ground to receive the greater benefit from the air, dews, rains, &c. to the great nouriſhment of all ſorts of plants, and by breaking up the ſurface, dividing the clods, and ſtirring the earth, keeps it freſh, it proves a very beneficial culture to all vegetables, as will be evident from practice and obſervation: in every ſoil; and in ſoils apt to bind

after much wet, which cauſes the plants to appear of a ſtinted growth, apply a Drawing-hoe, cutting deep enough to looſen the ground two or three inches down; it will encourage the plants to put out freſh fibres, add vigour, and greatly promote a free growth.

Likewiſe Hoeing up earth about the ſhanks of plants is a very eſſential piece of culture, ſuch as earthing up rows of peas, beans, kidney beans, cabbages, cauliflowers, &c. which is ever of great ſervice in promoting ſtrength and vigour in the plants.

HOT-BEDS. Beds formed either of horſe dung, or tanner's bark, raiſed two, three, or four feet high, and covered with garden frames, glaſſes, &c. deſigned to effect a certain degree of heat, for raiſing tender plants, and for forwarding others to early perfection.

By the aid of Hot beds we are able, in our northern climate, to imitate that of diſtant warm countries, ſo far as to exhibit their plants, flowers, and fruits often in very great perfection, which without ſuch artificial aids of heat, could not poſſibly be raiſed, nor continued in theſe parts of the world; for by the aſſiſtance of Hot beds, vaſt numbers of ſeeds, which would otherwiſe remain years in the earth, and ſome never grow at all, are made to germinate, form plants, continue their growth, and produce their flowers and fruits, as in their native ſoil. By Hot-beds, alſo, cuttings and ſlips of many ſorts of trees and ſhrubs, which would otherwiſe remain inactive and periſh, are made ſoon to emit fibres at bottom, and ſhoots at top, and become each a new vegetable.

Likewiſe by Hot-beds many of our valuable eſculents of the kitchen-garden, that ſucceed in the full ground at one time of the year or other, are brought to perfection a month or two ſooner than they would naturally attain in the open air, and ſome a quarter of a year or more ſooner than they could otherwiſe be obtained, exemplified in the cucumber, which by no art can be made to grow in the full air before May or June, nor be brought to produce fruit in the open ground before July; but by the aid of Hot-beds, are obtained often in the middle of winter, or early in ſpring: again, aſparagus, which grows all the year in the open ground, yet its natural produce never arrives to perfection before May or June; but by hot-beds we obtain it all the winter in any weather, from November until the arrival of the natural crops: peas, beans, kidney beans, raddiſhes, carrots, ſtrawberries, and various ſallad herbs and other plants, which grow in the open ground, are by Hot-beds forwarded to perfection a month, and ſometimes two or three, ſooner than they otherwiſe could be procured.

We alſo by Hot-beds forward many of our hardy fruits, as cherries, plums, apricots, peaches, grapes, figs, &c. ſix weeks or two months ſooner than they naturally would in the open ground.

By Hot-beds many beautiful and curious annual flowers are raiſed to perfection, that could ſcarcely attain to a flowering ſtate here in the full ground, See ANNUAL PLANTS.

And by Hot-beds many hardy flowers, both of the herbaceous and ſhrubby plants, are brought to flower in winter, and early in ſpring, which do not naturally appear before May and June, ſuch as pinks, carnations, ſweet-williams, narciſſus, jonquils, hyacinths, tulips, roſes, honeyſuckles, and various other plants of moderate growth, which you may incline to forward into an early bloom.

Hot-beds, therefore, are of the greateſt utility in gardening: they are, as before mentioned, compoſed of two principal materials, horſe-dung and tanners bark; the former of which is the moſt common ſort of Hot-beds for general uſe, have been already treated of under the articles BARK-BED, and DUNGS: it will, however, alſo be proper to give ſome hints reſpecting each in this place, under two ſeparate heads, viz. horſe-dung Hot-beds, and tanners-bark Hot-beds.

### *Horſe-dung Hot-beds.*

As horſe-dung Hot-beds are of general utility in gardening, I propoſe to handle this article at ſome length, for the benefit of thoſe unacquainted with their nature.

Horſe-dung Hot-beds are the moſt commonly uſed for all forcing-work in the kitchen-garden, for raiſing tender or early eſculents; alſo for working forcing-frames, to have early fruits and flowers; for this material, horſe-dung, being not only the moſt eaſily obtained in all places, but cheaper than Tanners-bark, the other Hot-bed material; beſides, that after having performed its office as a Hot-bed, it becomes rotten and buttery, and the moſt excellent manure that can be for the garden;

garden; ſo that horſe-dung Hot-beds are preferable for general uſe in the kitchen-garden. See DUNG.

The ſort of horſe-dung to be underſtood for the purpoſe of Hot-beds, is the dung and wet litter together, daily cleaned out of ſtables where horſes always ſtand, and are littered down with plenty of ſtraw every night, which being rendered wet by the urine and dung of thoſe animals, compoſes the principal material for a dung Hot-bed; for the dung alone without litter would do nothing, but the litter being thus moiſtened, and cleared out along with the dung, are both mixed together, and collected in any conſiderable quantity in a heap, or formed into a bed, its moiſture, by the urine and dung of the horſes, which is naturally of a ſtrong hot quality, quickly promotes a fermentation and ſtrong heat, often ſo violent as not to be able to bear one's hand therein, and even to burn the roots of plants, if any were planted while the vehement heat continues; but by a proper preparation is brought to a moderate degree of warmth, ſuitable to the growth of vegetables.

Obſerve alſo that the dung muſt be freſh; that is, ſuch as has been but a few weeks in collecting from the ſtables, or at leaſt that hath not lain ſo long in the dunghill as to exhauſt itſelf, and greatly loſe its heat, and beginning to rot; for the newer the dung the better, its heat proving always the moſt effectual and durable, provided it is properly prepared, as hereafter directed, previous to its formation into a bed. And although older dung may, by ſhaking up and mixing coal-aſhes therewith, be brought to heat a little again, yet it will be ineffectual, and of ſhort duration, and deceive you; nor ſhould you, if poſſible, uſe that very dry ſtuff, often to be met with, eſpecially that which has heated greatly, burned, and exhauſted its fermenting property in the dung-hill, appearing very dry, and of a whitiſh mouldy colour, for this will never acquire a proper heat; therefore always chuſe the freſh, or new-made ſteamy dung, full of moiſt litter, which, although ever ſo long or ſtrawey, if of a moiſt temperature, by mixing well together in a heap, the whole will acquire a proper fermentation for a Hot-bed; and the freſh dung will be of double the duration of ſuch that have lain long and exhauſted its firſt fermenting property, as above obſerved, in the dunghill.

Sometimes coal-aſhes are mixed with dung to promote a more quick and durable heat; which, however, is more neceſſary for dung that has ſomewhat exhauſted itſelf by being long in the dunghill, when by mixing a buſhel or two of aſhes to a cart-load of dung, will have ſome effect in contributing to the ſtrength and duration of the heat; but as to freſh dung full of heat, it requires no ſuch aid, and although it may help to continue the heat longer, yet is apt at firſt to promote a too fierce burning heat, therefore I would adviſe it to be uſed but ſparingly in freſh dung.

The dung, previous to its formation into a Hot-bed, ſhould be moved from the dung-hill, well mixed, and caſt up in a heap, or, if a large quantity, in a long high ridge, to lie a week or two to prepare it to a proper temperature for making the bed; therefore, with a dung-fork, take the long and ſhort ſtuff as it comes to hand, ſhaking it up, and mixing it all well together, in a pretty high heap, or ridge; to lie ten, twelve, or fifteen days, or more, as you ſhall judge proper, according to its quality, for all the parts to be equally moiſtened and meliorated, and for the ſtrong rank ſtench and ſteam to evaporate; and if in ſix, eight, or ten days, according to the quantity, the whole is turned over, caſting it up in a heap again, it will give greater vent to the noxious vapour and burning heat to paſs off, and by mixing the parts again, the whole maſs will be every way better prepared for the purpoſe of a Hot-bed: obſerving that without the above previous preparation of ſhaking the dung up in a heap, it is apt to heat violently when formed into a bed, ſo as to burn the earth thereof, as well as the roots of the plants, and ſend up a ſtrong rank ſteam, pernicious to all vegetables; and a Hot-bed of this burning quality, is apt to loſe its heat ſuddenly; for all which reaſons never omit preparing the dung as above for all kinds of dung Hot-beds.

With reſpect to the expoſure and ſituation wherein to make the Hot beds; all Hot beds ſhould be made principally in the kitchen-garden, in a ſunny ſheltered ſituation; and where the ground is rather dry, and free from ſtanding water at all ſeaſons; and it is of much importance to contrive to have the place in a part of the garden neareſt the dung, to have as ſhort wheeling as poſſible, which is an article of great attention where there is a conſiderable quantity of framing.

As to the preparation of the place for making the Hot-bed; dung Hot-beds are ſometimes made entirely on level ground, but moſt commonly in trenches, a foot or two deep; but for early work, in winter or ſpring, I ſhould adviſe to make the bed moſtly above ground; that when the heat declines, both ſides of the bed may be lined with hot dung quite to the bottom, ſo as the whole bed, from thence to the top, may have an equal benefit of the lining to revive its decaying heat; which lining is eſſentially neceſſary during winter, and in ſpring until the middle or latter end of May, when the heat of the ſeaſon renders them unneceſſary; whereas when the Hot bed is made in a trench, at an early ſeaſon, when linings muſt be added to ſupport a conſtant regular heat, all that part of the bed within the ground, is conſequently deprived of the advantage thereof, unleſs you ſhall dig the earth away all round, to the depth of the bed, wide enough to admit of a lining, for as all dung Hot-beds generally begin to decline their heat in three or four weeks, the heat muſt at any rate be revived or renewed accordingly, during the continuance of cold weather, by an augmentation of freſh hot dung, piled up againſt the ſides, which in practice is called lining the beds; and by applying theſe linings occaſionally, the heat of a dung Hot-bed may be continued four or five months, provided the whole bed from bottom to top can be thus lined: this, therefore, ſhews the neceſſity of making theſe Hot-beds for early work entirely on the ſurface of the ground; beſides, when Hot-beds are made in deep trenches in winter, water is apt to gather in the bottom, and chill the lower part of the beds; I would, therefore, alſo adviſe, that in low, or very moiſt ground, the place where the Hot-bed is to ſtand, to be rather a little the higheſt, particularly for early beds, that all moiſture from the dung, rains, ſnow, &c. may drain off. Some, however, are of opinion, that making Hot-beds in a deep trench, preſerves the heat longer; this in particular caſes as mentioned below, may have ſome effect, but is not proper at all where lining is neceſſary; therefore for early work, be perſuaded always to make the beds moſtly on level ground.

If it is, however, intended to adhere to the old method of making the Hot-bed in a trench, make the trench five feet wide, if for frames and lights; if for hand-glaſſes, or paper frames, three or four; and if in winter, not more than a foot deep; and if wet ground, half that depth is full enough, for the reaſons before aſſigned: but if towards ſummer, the trench may be made a foot and a half deep, that is, for Hot-beds in May, when the ground will be dry, the weather becoming ſettled, and no danger to be apprehended from copious ſtanding moiſture, and the warm ſeaſon nearly arrived, when but little aid of lining will be requiſite, may then with propriety be made in trenches, eighteen or twenty inches deep, as directed for the hand and bell-glaſs cucumbers and melons: and the whole bed thus made may be earthed all over ſo cloſely, as to cover every part of the dung, to confine the heat, that it may retain a due temperature without lining at all, till the middle or latter end of June, when the warm ſettled weather will be arrived, and the natural temperature of the ſeaſon will enable the plants commonly raiſed in theſe kind of Hot-beds, to ſucceed without any farther aid of artificial heat, the remainder of the ſummer.

As to the dimenſions of dung Hot-beds they ſhould generally be a parallelogram, or long ſquare, ranging nearly eaſt and weſt to any length convenient; about four feet and a half or five feet broad, if to be covered with common garden-frames; and three and a half or four feet, if for hand-glaſſes; raiſing them, if in winter, or early in ſpring, three or four feet high, allowing for ſettling, as they will ſettle a foot or more in a fortnight's time after making: and the early beds ought to be ſubſtantial, otherwiſe they will not ſupport a due uniform temperature of heat for the growth of plants at an early ſeaſon, which by aid of linings muſt be effected till the arrival of warm weather; obſerving however that Hot-beds made in winter ſhould be three feet and a half high at leaſt when firſt made, or if four the better. Thoſe made in March need not not be above a yard high, in April two feet and a half, and in May two feet may be a ſufficient thickneſs, and even eighteen inches about the latter end of that month; remarking as above-ſaid, that all Hot-beds are to be ranged lengthwiſe eaſt and weſt, or nearly ſo; but more eſpecially thoſe intended to be covered with frames, that they may exactly front the ſouth for receiving all poſſible benefit of the ſun. And as to the method of making the beds, ſee *Making the Hot-bed.*

Obſerve

Obſerve alſo, that all dung Hot-beds muſt be moulded or earthed at top, for the reception of ſeed and plants, covering every part of the dung at top that no ſteam may riſe therefrom without firſt paſſing through a body of earth, which otherwiſe, being of a rank pernicious nature, would prove deſtructive to moſt vegetables. Likewiſe, if the ſeed or plants are to be in pots, the bed muſt alſo be earthed at top, of due thickneſs in which to plunge the pots to their rims; remarking, that the proper depth of mould neceſſary to lay upon theſe Hot-beds is from about five or ſix to ten or fifteen inches, according to the uſe or nature of the plants to be raiſed therein, which is generally noticed in the reſpective articles; though from about five to eight or ten inches is the moſt common neceſſary depths of earth for dung Hot-beds. See *Earthing the bed*, below.

A Hot-bed may be made either for a one-light, two-light, or three-light frame, or for two, three, or more three-light frames in a range; the three-light frames being the moſt common ſorts for general uſe, eſpecially to receive plants from the ſmaller frames, to remain to grow to perfection, or to any conſiderable ſize. See FRAMES. But a Hot-bed deſigned chiefly as a ſeed-bed for raiſing a few plants for tranſplantation, as cucumbers, melons, tender annuals, &c. a bed for a ſingle frame, either a one-light or a two-light box, may be ſufficient, eſpecially for private uſe, or for early work, or may be for a three-light frame, according to the quantity of plants required. And as the tender plants raiſed in either of theſe frames advance in ſize, freſh Hot-beds of greater extent for two or three-light frames muſt be made for their reception, according to the directions given under the reſpective articles requiring the aid of Hot-beds: obſerving that all dung Hot-beds made in winter, or any time in ſpring, before the middle of April or beginning of May, ſhould generally be covered with frames and lights, eſpecially for tender plants. But Hot-beds made late, i. e. from about the the middle or latter end of April until the end of May, will ſucceed for ſeveral ſorts of plants, to be covered with hand or bell-glaſſes, alſo with oiled paper frames, as cucumbers and melons for latter crops, and for raiſing many ſorts of annual flower-plants that require forwarding in moderate Hot-beds. And late Hot-beds, for forwarding any of the more hardier ſorts of ſeeds, plants, and cuttings, in default of frames, or hand-glaſſes, &c. may be arched over with hoops, and covered occaſionally in bad weather and every night with mats until June; or you may contrive very cheap and eligible covers with oiled paper for theſe late Hot-beds, which are greatly preferable to mats, but under either of which may be raiſed many of the hardier annuals, as African and French marigolds, chryſanthemum, China aſter, ten-week ſtocks, &c. alſo ſtrike cuttings of many ſorts of plants; but for ſtriking many ſorts of the hardier cuttings that require aid of Hot-beds, oiled paper frames are the beſt covers that can be uſed for that purpoſe in May, June, and July; as they at the ſame time afford both ſhelter from cold, and ſhade from the ſun, yet admit its influence both as to light and heat in a proper degree for the work of vegetation.

According therefore to the above hints of dimenſions, &c. ſtake out on the ground the width and length of the intended Hot-bed, allowing, if for frames, for it to be two or three inches wider on each ſide than the frame; and according to that ſtandard may either make the bed entirely on the ſurface, or in a trench agreeable to the rules before laid down.

*Making the Hot-bed.*

To make the Hot-bed, ſhake ſome of the longeſt, or moſt ſtrawey dung along the bottom, to lay the firſt formation of the bed; then take it long and ſhort together as it comes to hand, and ſhake it evenly on every part, raiſing the ſides perfectly upright, ſtreight, and as firm as poſſible, forming the corners alſo always full and very firm, keeping the middle well filled with the beſt dung; and as you go on, beat each layer of dung evenly and firmly down with the dung-fork; or, if very long dung, it may be trodden, to ſettle every part equally. In this manner proceed till the bed is arrived to its deſigned, or neceſſary height, according to the ſeaſon, as before obſerved, or uſe it is intended for, as is always hinted in the reſpective articles, making proper allowance of a foot, or thereabouts, for ſettling; raiſing that intended for frames, two or three inches higher in the back or north ſide than in front, to give the greater ſlope of the glaſſes to the ſun, finiſhing the top even in every part; and when the bed is thus raiſed to the height intended, trim up all the ſhort dung remaining at laſt round the bed, laying it on the top ridgeways along the middle, which may either

then,

then, or rather, if a ſtrong bed, in a few days after, when the bed has ſettled a little, be levelled to make good all inequalities, and ſmooth the ſurface; then ſet on the frames, &c. and earth the bed agreeable to the rules hereafter laid down.

The proper frames and glaſſes in general uſe for theſe Hot-beds, are deſcribed under the article FRAMES. The common ſorts are one-light, two-light, and three-light frames; the two former generally for ſmaller purpoſes, as ſeed beds, or nurſery beds, for raiſing and forwarding plants for final tranſplantation into three-light frames; ſo that one or two of each of theſe ſizes may be ſufficient, and have a proper ſupply of the three-light frames for general uſe, as before obſerved. See FRAMES.

Hand-glaſſes for covering late Hot-beds are of two ſorts; ſquares, or leaded hand-glaſſes, and bell glaſſes. The ſquare glaſſes being four-ſquare, framed with lead, and many panes of glaſs, the glaſs being worked into the lead-work, are made by the glaziers, at from two to three ſhillings and ſix pence each, according to their ſize, ſtrength, and goodneſs of the glaſs. The bell-glaſſes are ſhaped like a bell, all of one piece, are blown at the glaſs-houſes, where they are ſold, from ten to fifteen pounds a hundred, or two or three ſhillings a-piece, and are rather preferable to the ſquare glaſſes for the growth and preſervation of plants, only there is this advantage in the ſquares, that if broke they can be readily mended; but the bells, when broken, are generally rendered uſeleſs, though if not broke into pieces, they may ſometimes be joined by a cement of white-lead colour; and the London gardeners, ſome of which work two or three thouſand hand-glaſſes in a ſeaſon, generally prefer the bells to the other ſorts. Either of theſe ſorts of glaſſes are proper to uſe for Hot-beds any time from about the middle or latter end of April to the beginning or middle of June.

Paper frames being light open frame-work, conſtructed like the roof of a houſe, or top of a covered waggon, and covered with oiled paper, are moſt excellent for ſummer Hot-bed work, i. e. Hot-beds made in May and beginning of June. See CUCUMBER and PAPER FRAMES.

Having, however, formed the Hot-bed for either of the above covers, if it is pretty ſubſtantial, particularly thoſe for frames, it will not be proper neither to frame it for good, nor earth it, for ſeveral days, until a little ſettled, and the firſt violent heat ſubſided; for the heat will be very ſtrong and frequently of a burning quality for the firſt week or two after it is made: it may, however, be proper to ſet the frames and glaſſes on both, to defend the bed from exceſſive rains or ſnow, and to draw up the heat ſooner, to forward the bed to a proper temperature for the reception of the mould and ſeeds, or plants, obſerving to tilt the upper ends of the lights a hand's breadth high, or ſhove them ſo much down in dry weather, that the great ſteam always ariſing in Dung Hot-beds may paſs freely off; for in ſtrong Hot-beds neither the earth, ſeed, or plants ſhould be put in till the fierce heat and violent ſteam has a little abated, which may be in ſix, eight, or ten days, or a fortnight, according to the ſubſtance of the Hot-bed, for that for one frame only, will ſooner work itſelf to a proper degree of heat for the purpoſe of vegetation, than a range for two or more frames, though a Hot bed of ſlender ſubſtance may be framed, &c. earthed and all, as ſoon as it is made, as no great danger is to be apprehended from burning, and more particularly thoſe for ſmall frames, hand-glaſſes, &c. but to Hot-beds of any conſiderable ſubſtance, either for one or more large frames, always uſe the above precaution previous to earthing, ſowing, or planting, eſpecially if you intend to ſow or plant in the earth of the bed; or even if you ſow or plant in pots, plunging them in the earth, that although they may be raiſed up, if there is danger of burning at bottom, yet but few plants thrive well when there is a very great ſteam and vehement heat.

Where there are a conſiderable range of ſubſtantial Hot-beds for many frames, the placing the frames thereon before they are to be fixed for good, may not be convenient; in which caſe it is proper, in default of the frames, to have mats, or dry long litter ready to cover the top, in caſe of exceſſive rains, or ſnow falling, which might chill and retard the bed greatly from becoming of a due temperature for the reception of the earth, &c. and ſometimes occaſions a bed to become of a burning quality, which otherwiſe would be of a regular temperature.

In ſtrong Hot-beds deſigned for ſtrength and duration of heat, it will, as ſoon as they are made, be proper to provide ſome ſharp-pointed ſticks, two feet long, to thruſt down into the middle of the bed in different parts, that

that by pulling out the ſticks daily, and feeling their lower parts, will enable you to judge of the working and temperature of the bed, to know more readily when of a proper ſtate for the reception of the mould and plants, which in ſtrong beds muſt not be truſted therein till the burning heat is paſt.

If the Hot-bed is, therefore, of good ſubſtance, and for the large frames, it is proper to let it remain ſome days to ſettle, before it is framed for good, becauſe, notwithſtanding all the care in making, it will often ſettle unequally, and ſhould be levelled before it is earthed; in from about three to five, ſix, or eight days, according to the nature of the dung, or ſubſtance of the bed, it will have ſo far ſettled as to diſcover the inequalities, if any; when, if the frames and glaſſes were placed thereon, for the purpoſes above mentioned, they muſt be taken off, and all the inequalities made even by levelling the top as you ſhall ſee neceſſary, making the ſurface firm, and ſmooth it off neatly with the back of the ſpade, and directly put on the frame, &c. for good; then, as a preſervative againſt burning the earth by the violent heat of the bed, ſome freſh neat's dung, if it can be conveniently procured, may be ſpread upon the top of the bed, particularly along the middle part, an inch thick or more, eſpecially in ſtrong Hot-beds, under frames for ridging-out cucumbers and melons, plaiſtering it under the middle of each light, where each hill of plants is to ſtand, in circular patches, about eighteen inches or two feet diameter, as directed in the article CUCUMIS, for cucumber and melon Hot-beds: this done, put on the lights, tilting them at top to give vent to the ſteam, as before obſerved; and as ſoon as the bed is become of a moderate temperature, and there is no danger from too violent a heat, put on the earth, to receive the ſeed or plants.

With reſpect to earthing the bed; obſerve that ſubſtantial dung Hot-beds for frames, after being covered with the frames, &c. they ſometimes heat violently the firſt week or fortnight; and that if the earth was put in during the fierce heat, it, by confining the heat and ſteam ſtill more cloſely, will be in danger of being burnt to a whitiſh mouldy colour; and burn alſo the roots of the plants, if any were ſown or planted; and when the earth is thus burnt by the heat of the dung, no ſeeds nor plants can vegetate or thrive in it; ſo that when this happens to be the caſe, all the earth muſt be taken out, and replaced with the like quantity of freſh compoſt. Therefore, in Hot-beds of any conſiderable ſubſtance, either for one or more frames, examine, previous to moulding it, its ſtate of heat daily with good attention, both by the ſticks, and by thruſting your hand down into the dung: thus you will judge regularly of the working of the bed from its firſt formation, to its greateſt heat; and thence till the vehemence of it begins to abate, and become proper for vegetation; then prepare to put in the mould. It is an obſervation worth notice, that when a ſort of *fungi*, or ſpawn of the muſhroom tribe, which often riſe in dung Hot-beds, begins firſt to appear, is a certain ſign that the Hot-bed, if ever ſo ſtrong, is in a proper temperature both for the reception of earth, and plants.

But, as we formerly noticed, ſlender Hot-beds, made but about eighteen or twenty inches depth in dung, ſeldom require ſo much precaution as above, which is directed chiefly for ſtrong beds, made from about two to three or four feet high, for large frames, to ſhew what is often abſolutely neceſſary to be done, for the benefit of the plants to be cultivated in them: therefore as to ſlender Hot-beds, as their heat is never ſo violent nor durable, may, according to their ſubſtance, either be earthed as ſoon as made, or in two, three, or four days after, as you ſhall judge proper by the above rules, which is moſt commonly mentioned in the different articles.

Obſerve, however, even in the ſtrongeſt Hot-beds, to watch the opportunity of its proper temperature; not to loſe any time, for it to waſte its heat ineffectually, without being earthed, ſowed, or planted.

The earth for all ſorts of Hot-beds, ſhould be rich and light, and of a dry temperament; but more particularly for early work in winter and ſpring, eſpecially for tender plants, ſuch as cucumbers, melons, tender annuals, &c. for very moiſt earth rots ſuch tender plants while young, binds too cloſe, and by its compactneſs confines the heat and ſteam, ſo as to burn at bottom, and ſcorch the roots of the plants; let, therefore, ſome mould be always ready, drying in ſome airy ſhed, two or three weeks before-hand, for early work. See COMPOSTS.

The depth of earth neceſſary to be laid on theſe Hot-beds, is according to the purpoſes for which the Hot-bed is deſigned, whether principally for ſowing ſeed, or for the reception of plants, and according to the nature of the

plants, or whether deſigned chiefly for plunging pots; but generally from about five or ſix, to ten or twelve inches, is the common depth; obſerving if for ſowing ſeeds to raiſe plants for tranſplantation, the depth of mould to be from about four to ſix inches, and if the plants are to remain where raiſed, to acquire their full growth, not leſs than from about ſix or eight to ten or twelve inches depth of earth, will be requiſite; and if for the immediate reception of plants, to remain, or for ſtriking cuttings of any ſort, &c. from about ſix to eight, ten, or twelve inches of mould will alſo be neceſſary, according to the ſize or growth of the plants; for thoſe which naturally have large tops, either ſpreading like cucumbers, &c.or upright growers, muſt have depth enough of mould for their fibres to draw proper nouriſhment to ſupport their ſtalks and branches; as for example, cucumbers and melons being very branchy ſpreading plants, producing large fruit, conſequently require more ſubſtance of earth than ſmall ſallad herbs, and ſo in proportion to other plants that are to grow to perfection in the Hot-bed: and if for plunging pots, containing either ſeed or plants, ſeveral inches of earth is neceſſary, according to the ſize of the pots, in which to plunge them, without going into the dung of the bed; therefore, according to theſe hints, you will readily judge of the proper depth of the earth generally neceſſary upon dung Hot-beds; other particulars are exhibited under the reſpective articles.

In earthing the beds, be careful to cover every part of the dung within the frame therewith, eſpecially after the plants are come up, or any planted, that no ſteam may riſe immediately from the dung upon them, for the ſteam of horſe-dung being of a very rank cutting nature, as is evident by its effect upon one's eyes, that if it attacked the plants, without firſt paſſing through a body of earth, would deſtroy moſt ſorts it encounters in its paſſage from the dung; which is called ſteaming the plants.

With regard to ſowing or planting ſeeds or plants in the above Hot-beds, obſerve as directed for moulding the bed, that if the bed is of ſtrong ſubſtance, and under frames, be careful neither to ſow nor plant till the danger of burning is over, eſpecially not unleſs the ſowing or planting is performed in pots, that may be moved up as occaſion requires; but at any rate it is always better to wait a day or two, than to endanger burning good plants: do not, however, loſe time when the bed is ready, for it is neceſſary always to have a lively heat at firſt to promote a quick germination in the ſeeds, or to ſtrike and ſet the plants a-going, ſo as to aſſume a free growth at firſt ſetting off; ſo that in ſlender or very moderate Hot-beds, the ſeeds and plants may be committed to the earth as ſoon almoſt as it has acquired a little heat.

And as to the method of ſowing the various ſeeds and plants commonly raiſed in theſe Hot-beds, it being different according to the ſorts, ſo is generally exhibited under each reſpective article.

In reſpect to the management of the Hot-beds after being ſowed or planted with ſeeds or plants, it is often different, according as the different plants may require, but take the following general hints: the ſeed or plants being put in, the glaſſes are to be continued conſtantly on until June or July, when the weather is become ſettled and warm, particularly to all the tender kinds of plants; freſh air, however, muſt be admitted daily, at all opportunities in mild weather, by tilting the upper ends of the lights, or, if hand glaſſes, by propping up one ſide, from about half an inch to three or four high, according to the heat and ſteam in the bed, and temperature of the outward air; ſhutting all cloſe in due time towards evening, and muſt be kept cloſe every night during the cold weather; cover alſo the glaſſes every night with mats until June, eſpecially for the more tender ſorts of plants; one or two mats thick may be ſufficient covering while the bed is in full heat; but when it decreaſes, you may augment the covering by the addition of another mat; never ſuffering the mats to hang down low over the ſides of the frame and bed as is often practiſed intentionally to keep out the cold more effectually; but this not only excludes the free air too much, to the great detriment of the plants, by drawing them up weak, and of a ſickly yellow colour; it alſo promotes a rank ſteam, pernicious alſo to the health of all vegetables, and often proves the death of many of the more tender herbaceous tribe.

When the firſt great heat of the bed is abated, which may be in a week or fortnight after it is made, if in winter or early in ſpring, when cutting winds, or driving cold rains and ſnow may be expected, it is good culture to lay a quantity of dry long litter, either ſtraw, waſte hay, or fern, round the ſides of the bed, quite from the

the bottom, half a foot or more thick, and as high up the frame as the earth withinſide reaches: it will greatly preſerve the heat in a proper temperature, and the bed will not require to be lined ſo ſoon as it otherwiſe would do.

But when the heat of the bed naturally declines, or becomes of a weakly temperature, it muſt be renewed by adding freſh hot dung around the ſides, which is called lining the bed, and is particularly neceſſary for all dung Hot-beds, made any time in winter or ſpring, until the beginning or middle of May, that are deſigned to continue plants any conſiderable time; but thoſe Hot-beds made in May generally ſupport a due degree of heat without lining, until the arrival of warm ſettled weather, as before obſerved. With reſpect, however, to linings to early beds, they may ſometimes require a repetition of new linings three or four times, eſpecially thoſe made in winter, to continue them in a uniform heat; theſe linings ſhould be of the hotteſt dung, and applied quite from the bottom to the top of the bed, and about eighteen inches wide at bottom, drawing it in to about a foot wide at top, raiſing it four or five inches up the frame, to allow for ſettling, but not more, for the top of the linings, when ſettled, ſhould be but very little above the bottom of the frame, leſt its heat burn the earth adjoining to the frame withinſide: and to prevent ſteam from riſing too copiouſly from the linings, lay a ſtratum of earth on the top, two inches thick, continuing it cloſe up to the bottom of the frame, that no ſteam may ariſe that way, for the rank ſteam immediately from dung, without firſt paſſing through a body of earth, is deſtructive to moſt plants; according as the lining ſettles down lower than the top of the bed, add more freſh dung, obſerving the precautions as above; and when the heat of the lining is exhauſted, it muſt be renewed with a freſh quantity of dung, or ſome of the beſt of the former lining may be ſhaken up and mixed with a good quantity of new, and worked up in a lining, as before directed; in this manner we muſt continue to ſupport the heat of dung Hot-beds as long as the aid of artificial heat is requiſite for the growth of plants contained therein. See LINING.

For Tanner's-bark Hot-bed, ſee BARK-BED, where it is fully explained.

HURA, Sand-box tree.

It is an exotic tree of South-America, kept here in our hot-houſes for variety, and for the beauty of its ample cordated foliage; producing monoecious flowers, ſucceeded by large ſwollen capſules in America, where the natives uſe them for ſand-boxes, for writing deſks: whence it derived the appellation Sand-box tree.

Claſs and order, *Monoecia Monadelphia.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant, the males in an oval amentum, each floret having a ſmall two-leaved cup, which in the female is monophyllous and ſwelling. COROLLA, none. STAMINA, one filament, and a double ſeries of antheræ. PISTILLUM, a roundiſh germen in the bottom of the calix, a very long cylandrical ſtyle, and large funnel-ſhaped ſtigma, divided into ten equal ſegments. PERICARPIUM, a globular, ligneous, twelve-furrowed fruit, of twelve cells, and ſo many ſeeds, burſting open at top with an elaſtic force and great noiſe.

The ſpecies is;

HURA *Crepitans.*

*Exploſion-tree, or American Hura, commonly called Sand box-tree.*] Hath an upright, ſoft, ligneous ſtem, dividing into a branchy head, riſing twenty feet high, adorned with large heart-ſhaped leaves, eight or ten inches long, and near as broad, on long foot-ſtalks; and monoecious, apetalous flowers, the males in oval amentums, the females ſeparate, having each a very long ſtyle, and large funnel-ſhaped ſtigma, divided at the brim into ten ſegments, appearing like petals, ſucceeded by a large round, compreſſed, woody capſule, with twelve deep furrows, and ſo many internal cells, and the like number of ſeeds, which when ripe, the capſules burſt with an elaſtic force and exploſion, ſometimes equal to that of a piſtol, diſcharging the ſeeds to a conſiderable diſtance.

The whole plant abounds with a milky juice, and the ſtalk and branches are ſomewhat ſucculent.

This beautiful and curious exotic being a native of the hotteſt regions, in this country muſt always be kept in the hot-houſe; potting it, therefore, in pots of rich light earth, and plunge them into the bark-bed, where the plants will attain twelve or fifteen feet ſtature, and frequently produce flowers; watering it ſparingly in winter.

Its propagation is by ſeed; theſe are procured from abroad by the importers of ſeeds, generally arriving in the ſpring, which ſhould be ſowed as ſoon as poſſible in pots of rich earth, and plunged in a bark hot-bed; when

the plants are come up about three or four inches high, plant them out into ſeparate ſmall pots, giving water, and plunge them alſo into the tan-bed, or into that in the ſtove, retaining them always there, ſhifting them into larger pots occaſionally. See STOVE PLANTS.

HUMULUS, the Hop-plant.

One ſpecies only conſtitute this genus; a hardy climbing perennial, producing annual ſtalks, twining round any ſupport to a great height, terminated by ſcaly cluſters of flowers and fruit, of admirable value to the brewers, in procuring an agreeable bitter to beer, rendering it more wholeſome, and keeping it from ſouring.

Claſs and order, *Dioecia Pentandria.*

*Characters.*] CALIX, male and female flowers on different plants; the males having a five-leaved cup, and the females a quadrifid, acute, general involucrum, and the partial one four-leaved, and contains eight florets, each furniſhed with a monophyllous perianthium. COROLLA, no petals. STAMINA, five capillary filaments in the males, and oblong antheræ. PISTILLUM, a ſmall germen, two awl-ſhaped, reflexed, ſpreading ſtyles, and acute ſtigmas. PERICARPIUM, none. SEMEN, a roundiſh ſeed ſucceeds each female floret, lodged in the baſe of the calix.

There is but one ſpecies, which admits of two varieties; the male hop—and female hop.

The ſpecies is;

HUMULUS *Lupulus.*

*Humulus, or Hop-plant, formerly, Lupulus.*] Hath a long, ſlender, fibrey, perennial root, ſending up annually ſeveral climbing, long, ſlender, rough, tough, purpliſh ſtalks, twining round any ſupport fifteen or twenty feet high; adorned with large palmated rough leaves, on long foot-ſtalks, and whitiſh-yellow, apetalous, ſcaly flowers, in pendulous cluſters from the ſides and ends of the ſtalks; appearing in July, and the ſeed, and ſcaly covers, which are the Hops, ripen in Auguſt and September.

*Varieties.*] Male Hop-plant, bearing male flowers only, growing in long cluſters—female Hop-plant, bearing female flowers only, produced in roundiſh, ſcaly, leafy cluſters.

The male Hop grows wild in hedges and bank ſides, and is never cultivated: its young ſhoots, however, in ſpring, prepared like aſparagus, affords a palatable food.

The female Hop is the only ſort that is cultivated, and admits of ſome varieties, by the Hop-planters termed: early white Hop—long white Hop—oval Hop—ſquare garlick Hop, &c. and theſe varieties of female Hop-plants are the ſorts cultivated, to produce that valuable commodity called Hop, well known to all for its excellent properties in improving all ſorts of beer and ale.

Theſe plants are rarely cultivated in gardens, except a few, by way of climbers, for variety; for they will twiſt round poles, or any ſimilar ſupport, twenty feet high or more.

They are very hardy, and will grow any where; obſerving, however, thoſe intended for uſe, ſhould have an open ſunny expoſure, and as good ground as poſſible; in any open field that produces good graſs or corn, prepared for their reception by digging or ploughing; though when large quantities are cultivated for ſale, ploughing is the moſt expeditious and cheapeſt tillage; and the ſets, i. e. cuttings of ſuckers from the root are planted in rows, ſix or eight feet aſunder in ſpring, which ſhoot up the ſame year into ſtalk, and produce ripe Hops in autumn; and the roots abiding for years, ſend up a freſh crop annually.

*Propagation and Culture.*

Their propagation is by cuttings of the ſuckers ariſing immediately from the roots within the ground, every part of which will grow, cutting them ſix or ſeven inches long, each having three or four buds, or eyes, for emitting ſhoots, and are taken from the roots of the plants, of any old plantation in full perfection of bearing; being particular to chuſe good ſorts, and ſuch that are good bearers, trimming each ſet from all old vine, and any hollow, or bad part: the ſpring of the year, at Hop-dreſſing time, is the proper ſeaſon for procuring the ſets; that is February, March, and beginning of April; they may alſo be propagated by layers of the young ſhoots in ſummer; cutting off their tops at the time of laying, they will root and form ſets for next ſpring.

It is of conſequence to be choice in the ſort of Hop to plant; they ſhould be all of a a ſort, not early, middle, and late kinds planted together, which by ripening at different times, would occaſion great trouble in gathering.

The early white Hop comes firſt, is a fine Hop, but an indifferent bearer. The long white Hop is next, is a good bearer, and valuable

luable ſort. The ſquare garlick-hop is lateſt, is a plentiful bearer, but a coarſer Hop than the former.

March and April is the proper time for planting them.

The ground ſhould be well digged, or elſe deeply ploughed, and well rough-harrowed, to break all clods, and render the ſurface fine and ſmooth; and if the ground is rather poor, ſome well-rotted dung, or a compoſt of dung and earth together, may be laid in heaps to mix in each hole.

Then having the ſets ready, proceed to plant them by line, in ſtraight rows, ſix or eight feet diſtance, and the ſame diſtance in each row, in the quincunx order. Be provided with a long line, to reach quite acroſs the ground, and in which, at every ſix or eight feet, tye a knot, or ſmall bit of rag; then ſtretching the line, and having a quantity of ſmall ſharp-pointed ſticks, place one down at each of the marks, and in each place a hole is to be digged, a foot and a half wide, and filled up again with the earth and rotten dung, for the reception of the plants, four or five in each, as directed below; having thus marked out one line, remove it ſix or eight feet farther, placing it ſo as the marks thereon may be oppoſite the middle of the ſpaces or intervals of the firſt row, that the plants may ſtand in the quincunx form, and place the ſticks as before; ſo on to a third, and every row to the end. But the way to have them in an exact quincunx order, is to have a triangular gage, made with three pieces of pan tile lath, &c. eight feet long, joined together in form of a triangle, making the ends croſs each other, about an inch or two in a forked manner; then having placed one row of ſticks by line, as above, apply two ends of the triangle to two of the ſticks, one ſtick between each fork, and then plant a ſtick in the fork of the other end of the gage, to form the next row; thus moving the triangle along, place it to two more ſticks in the firſt row, as before, plant another ſtick in the fork of the other end, and ſo proceed to the end of the row, and in the ſame manner ſet out every row till the whole is completed; thus you form an exact quincunx, and the plants will alſo range exactly every way, and appear very beautiful when they are poled.

Then, where each ſtick ſtands, dig a round hole about eighteen inches wide, and a moderate ſpade deep, breaking the earth well, caſting ſome out, and add to the reſt ſome of the rotten dung or compoſt from the heaps laid for that purpoſe, mixing it well with the earth of the holes, forming it in a ſort of hillock in each hole; tho' where the ſoil is freſh and naturally good, there will be no abſolute neceſſity for dung; ſo may only dig the holes to looſen the earth well, at the ſame time drawing ſome of the top mould on each ſide round the hole in a ſmall hillock, the width of the hole, and two or three inches high, levelling the top, and hollow it a little; the places thus prepared in either of the above methods, are ready for the plants.

The plants, or ſets, are then to be planted four or five in each hill, with a dibble, one in the middle, and the reſt round it, at four inches diſtance, and all nearly even with the general ſurface, preſſing the earth cloſe about them, and cover them over with finely-broken mould as you go on, and this finiſhes the work.

The plantation being thus formed, the next care is to keep it clean from weeds by hoeing: the firſt hoeing will be requiſite in May, chuſing dry weather, and, as you proceed, draw a little mould round about each hill to form a greater body of earth immediately about the plants, continuing the hoeing during the ſummer as there ſhall be occaſion.

The plants will ſhoot forth into vine tolerably ſtrong, early the ſame year; ſo that in May ſmall poles may be placed to each hill, for them to run upon, as hereafter directed, and they will produce a few hops the ſame year, though ſome do not pole them at all the firſt ſeaſon, only twiſt the vine into a bunch in June, at the top of each hill, regardleſs of any crop, as it is apt to weaken the young plants.

The next neceſſary work is in ſpring following to dreſs or prune the Hops, and February and March is the proper ſeaſon, when the ground is to be dug or ploughed, and the earth about the hills of plants, be removed away near to the ſtocks or roots, clearing it quite away from the tops of the principal roots with an iron picker, for the convenience of pruning cloſe to the head of the ſtock; then with a ſharp knife trim off all ſhoots of laſt year, or the remaining part of them, cloſe to the head of the ſtocks or ſets; clearing away alſo all young ſuckers, and directly trim in the earth around each hill, and cover the top of the ſtocks with mould two or three inches thick; and this is to be every year repeated.

After

After this the plants will ſoon ſhoot forth into vine, or bind, when long poles about fifteen or twenty feet in length, muſt be placed for them to run upon: April or the beginning of May, when the ſhoots are a foot long, is the ſeaſon for this work, three poles muſt be ſet to each hill, around the outſide, let deep into the ground, by making holes for them with an iron crow, ſo as to place them with their top inclining a little outward from each other, to keep the plants from entangling, and a ſpace between two of them be left open toward the ſouth, to admit the ſun more freely.

The Hops being thus poled, they will for the general part naturally twine themſelves about the poles, obſerving to direct ſuch with the hand as do not readily catch hold of themſelves, turning them the way of the ſun's motion, and tie them looſely with dried ruſhes or other ſoft bandage, training two or three vines to each pole, and all above that ſhould be plucked up, if the plantation be old; but if young, wrap them up together in the middle of the hills.

The next work is ſummer-digging, in the beginning of June, which is digging about the hills, and caſting up ſome fine earth around, and upon each, which is ſometimes repeated again the beginning of July, to make all the hills of a proper ſubſtance, for the better nouriſhing of the plants.

After the plants are grown up, if you find any of them under-poled, taller poles muſt be placed near thoſe that are too ſhort, to receive the vines from them; for unleſs they have due length of pole, they will not yield a full crop; and if the vines are very ſtrong, and over-top the poles, it is common to ſtrike off the heads of the ſhoots with a ſwitch, whereby they throw out many lateral branches, well charged with cluſters of fruit.

In July the Hops will blow, and towards the end of Auguſt will begin to ripen; the tokens of which are the bunches of fruit imparting a ſtrong Hop-like ſcent, dry and hard to the touch, and browniſh colour of the ſeed.

At theſe tokens of maturity the Hops are fit for gathering, when they ſhould be picked with all poſſible expedition, for a ſudden ſtorm of wind, or great rains would do conſiderable damage, by breaking down the vine and diſcolouring the Hop.

This work of picking Hops muſt be performed in dry weather if poſſible.

A certain number of hills in a ſquare ſpace is to be cleared at a time, generally about eleven, and a large ſquare bin, or wooden frame eight feet long, by three broad, having a cloth within hanging on tenter-hooks, is to be placed in the centre to receive the Hops; then proceeding to the work of picking, cut up the vine of the above number of hills, and pull up the poles, uſing a wooden inſtrument like a lever, having at one end a forked piece of iron with teeth on the inſide, which will readily raiſe them out of the ground; then laying two poles at a time acroſs the bin, and two or three perſons may ſtand on each ſide to pick the Hops therein, picking them very clean without leaves and ſtalks; and as the bin is filled, it muſt be emptied two or three times a day, as there may be occaſion, into a hop-bag, and carried to the kiln to dry.

The kiln for drying Hops is the ſame as a malt-kiln, covered with a hair cloth, on which they ſpread the hops, which ſhould be ſpread ten or twelve inches thick; and a charcoal fire is commonly uſed, continuing an even ſteady fire, not fierce, but rather increaſe it by degrees, and in about nine hours let the Hops be turned, and in two or three hours more, they may be taken off, by that time the brittleneſs of their ſtalks, and eaſy falling of the leaves determine them to be ſufficiently dried.

They are then to be carried into dry upper rooms, to lie three or four weeks to toughen, otherwiſe they would become powder in bagging.

The bagging is performed in large bags made of about four ells and a half of ell-wide coarſe cloth; about a handful of hops is firſt tied into each corner at bottom, to ſerve as handles; the bag is then faſtened to a hole of due width in the floor, made for that purpoſe, having a hoop faſtened to the mouth of the bag, on which it reſts on the edges of the hole; then a perſon puts the hops into the bag, while another is continually treading them down, till the bag is full; the bag is then unfaſtened from the hoop, and let down, and cloſe up the mouth, tying a handful of Hops alſo in each corner, as in the bottom part, they are then ready for market.

The moſt conſiderable plantations of Hops in England, are in Kent and Surry, and ſome parts of Suſſex and Hampſhire, but more particularly Kent, where the Hop gardens exhibit a delightful appearance in ſummer, and from

from which county it is amazing to ſee the numbers of great waggon loads daily brought to London in September and October, principally to the Borough of Southwark, where are the great magazines of them for the ſupply of the brewery; great quantities are alſo brought by water, and depoſited in warehouſes in Thames-ſtreet, belonging to the hop factors.

A plantation of Hops will continue in good bearing ſeveral years, provided the ground is properly manured.

The proper manure is well-rotted dung, or a compoſt of dung and earth together, prepared ſome time for that purpoſe; and of either from about twenty to forty cart load, is the common allowance for an acre; the former quantity is generally allowed when dung is ſcarce, laying it only along the hills of plants to be dug in, in winter or ſpring, but the beſt way is to allow about forty load, and dig or plough it in any time from October till March; and ſuch a dreſſing need not be repeated but once in two or three years.

Every year after the ground is cleared from the Hops, care ſhould be taken of the poles, which if they could be laid under any covered place, would greatly preſerve them; but for want of ſuch convenience, they are placed in parcels upright in the open air, firſt fixing three or ſix poles firmly in the ground, in a triangle manner, wide at bottom, and tied together at top; then ſet as many of the reſt of the poles about them as ſhall ſeem convenient in each parcel.

As the poles decay, they muſt be recruited with new ones.

The poles may be of any wood, but the ſorts commonly uſed are aſh, birch, maple, ſycamore, willow, poplar, and cheſtnut, the latter of which is the moſt durable of all.

It requires about three thouſand poles to an acre, allowing three to each hill.

HYACINTHUS, Hyacinth, and the *Muſcari*, or Muſk Hyacinth.

The plants are low, herbaceous, bulbous-rooted, flowery perennials, for the flower-garden and open borders; ſending up annually from the root, long narrow leaves, and upright flower-ſtalks, from about half a foot to twelve or fifteen inches high, terminated by many bell-ſhaped ſix-parted flowers, in a large erect ſpike; ſome of which are of admirable beauty and elegance, and the floriſts pride, particularly that celebrated ſpecies the *Hyacinthus Orientalis*, which comprehends ſome hundreds of delightful varieties, all beautiful ornaments of the ſpring.

Claſs and order, *Hexandria Monogynia*.

*Characters.*] CALIX, none. COROLLA, is monopetalous, bell-ſhaped, ſix-parted, and reflexed at top, and three ſmall nectariums like pores, placed on the point of the germen. STAMINA, ſix ſhort ſubulate filaments and connivent antheræ. PISTILLUM, a roundiſh, trigonous, three-furrowed germen, ſhort ſtyle, and obtuſe ſtigma. PERICARPIUM, a roundiſh, trigonous, trilocular capſule, and roundiſh ſeeds.

To this genus the botaniſts have joined the *Muſcari*, or Muſk and Grape Hyacinth, which before was always conſidered as a diſtinct genera. There are in the whole about thirteen ſpecies of *Hyacinthus*, and of which the following are thoſe principally retained in the Engliſh gardens.

1 HYACINTHUS *Orientalis*.

*Oriental, or Eaſtern Hyacinth.*] Hyacinthus, with a large, purpliſh, bulbous root, ſending up ſeveral narrow erect leaves, eight or ten inches long, amidſt them; an upright, robuſt, ſucculent flower-ſtalk, from about ten to fifteen inches high, adorned upward with many large funnel or bell-ſhaped flowers, ſwelling at the baſe, and cut half way into ſix parts; collected into a large pyramidal ſpike, of different colours in the varieties; flowering in April and May.

*Varieties are.*] Oriental Hyacinth, with ſingle white flowers—double white flowers——red ſingle and double flowers—fleſh-coloured ſingle and double flowers——blue ſingle and double flowers—purple-blue ſingle and double flowers.

Of each of the above ſorts, there are many intermediate varieties, amounting in the whole to ſome hundreds, differing from one another in ſome reſpect or other, as in the ſhades or teints of each reſpective colour; the ſize and poſition of the pips or florets, their number and mode of arrangement in each ſpike, the form and ſize of the ſpikes, and ſome other variations; all of which varieties have been obtained from ſeed, and by which many new ones of the above principal ſorts are annually gained; each variety is, by the floriſts, diſtinguiſhed either by the name of the place where firſt raiſed, or perſon who raiſed them, or that of illuſtrious perſonages, as the greateſt kings, the braveſt generals, famous poets, and celebrated

brated ancient hiſtorians, the gods, goddeſſes, and the like; often beſtowing ſuch names on them as denote their value: ſo that in this prodigious multitude now of many hundreds, and new ones annually acquired, to which names are given, according to the fancy of the different propagators, it would be impoſſible to exhibit any accurate liſt here of any thing ſo variable, but the names of the capital varieties moſt in vogue, are always to be found in moſt of the eminent ſeedſmen's catalogues; who alter or make additions according as new ſorts occur.

This ſpecies of Hyacinthus and its varieties poſſeſſing a degree of pre-eminence above all the other ſpecies of this genus, are the ſorts commonly eſteemed and cultivated by the floriſts, and the ſorts generally meant and underſtood, when we ſpeak ſimply of the Hyacinth.

[2]HYACINTHUS *Non-ſcriptus*

*Wood Hyacinth, or Hare-bells.*] Hath a ſmall bulbous root; narrow leaves, five or ſix inches long; upright flower-ſtalks, ſix or ſeven inches high; and bell-ſhaped, ſix parted blue flowers, revolute at top, ranged all on one ſide of the ſtalk, appearing in March and April.

*Variety.*] With white flowers.

Both the varieties grow wild in our woods and hedges; and are cultivated in many gardens as furniture for wood-walks, wilderneſſes, &c.

[3]HYACINTHUS *Cernuus.*

*Nodding-flowered Spaniſh Hyacinth.*] Hath a ſmall bulbous root; narrow erect leaves, five or ſix inches long; an upright flower ſtalk, ſix or ſeven inches high; bell-ſhaped red flowers, ranged on one ſide of the ſtalk, and the top of the ſpike nodding or bowing downward; flowering in April.

[4]HYACINTHUS *Amethyſtinum.*

*Amethyſtine-coloured Hyacinth.*] Hath a ſmalliſh bulbous root; upright robuſt flower-ſtalk, a foot high, terminated by many ſmall bell-ſhaped flowers, cylindric at the baſe, and cut at top half into ſix parts, of a deep amethyſtine-blue colour; flowering in February and March.

The following are the Muſcari Hyacinths, diſtinguiſhed by their corolla being more globular and ſwollen than the former ſorts.

[5]HYACYNTHUS *Muſcari.*

*Muſcari, or Muſk Hyacinth.*] Hath a large oval bulbous root, ſending up ſeveral narrow, furrowed, thickiſh leaves, eight or nine inches long, ending in obtuſe points; an upright flower-ſtalk, half a foot high, adorned with oval, reflexed, faded purple flowers, imparting a ſtrong muſky adour.

*Varieties*] With purpliſh flowers below, and yellow at top—and with large yellow flowers.

[6]HYACYNTHUS *Comoſus.*

*Tufted Hyacinthus, commonly called Fair-haired Hyacinth*] Hath a large bulbous root; narrow, ſword-ſhaped leaves, a foot long, diminiſhing to a ſharp point; an upright flower-ſtalk, about a foot high, adorned with angular cylindric flowers, terminated by a tufted cluſter of oval florets, deſtitute of the generative organs; of different colours in the varieties; flowering in April and May.

*Varieties.*] Tufted Hyacinth, with purple flowers—with blue flowers—and with white flowers.

[7]HYACINTHUS *Monſtroſus.*

*Feathered Hyacinth.*] Hyacinthus, with a large bulbous root, ſending up ſeveral narrow, plane, ſmooth leaves, a foot long, ending in obtuſe points; upright flower-ſtalks, a foot and a half high, the upper half garniſhed with many oval blue flowers, in tufted panicles, having finely cut feathered-like petals, moſtly deſtitute of the parts of fructification, ſo never produce ſeeds; appearing in April and May.

[8]HYACINTHUS *Botryoides.*

*Grape Hyacinth.*] Hath a ſmalliſh bulbous root; many narrow, cylindric, canaliculated, erect leaves, half a foot long; an upright ſtalk, ſix or eight inches high, adorned with many ſmall globular, cloſely-placed flowers, in a cluſtered ſpike in the manner of a bunch of grapes; of different colours in the varieties; appearing in April.

*Varieties.*] Grape Hyacinth, with blue flowers—white flowers——and with aſh-coloured flowers.

[9]HYACINTHUS *Racemoſus.*

*Racemous Grape Hyacinth.*] Hath a middle-ſized bulbous root; ſword-ſhaped looſe leaves, ſix or eight inches long; a flower-ſtalk ſix inches high, terminated by many ſmall oval blue-flowers, in a racemoſe-cluſter, cloſely placed at top; flowering in April.

The flowers of all the ſorts, in their characteriſtical, or ſingle ſtate, conſiſt of one hollow, ſomewhat bell-ſhaped petal, cut more or leſs into ſix parts at top; but in the double flowers, the petals are multiplied in ſeveral ſeries, one within another, as in the double

Oriental

Oriental Hyacinth, the flowers of which are conſiderably the largeſt and moſt beautiful of all the ſpecies.

All theſe ſpecies of Hyacinthus, and their reſpective varieties, are hardy bulbous rooted perennials, of great duration in root, but annual in leaf and ſtalk; the leaves ariſing from the root in ſpring, and amidſt them the flower-ſtalk; but one generally from each bulb, is naked, or without leaves, and the upper part is terminated by the flowers, commonly in a ſort of ſpike; in ſome extended wide at bottom, upon their pedicles, diminiſhing gradually to the top, in a pyramidal form, as obtains in moſt of the varieties of the Oriental Hyacinth; flowering principally in April and May, ſucceeded by plenty of ripe ſeed in June and July; then the leaves and ſtalks decay, and the roots loſe their fibres, and become inactive for a month or ſix weeks; during which period is the time to liſt the roots, as may be neceſſary in ſome ſorts annually, eſpecially the Oriental kinds, and in others every two or three years, to ſeparate the increaſed off-ſets from the main bulbs, and to tranſplant them into freſh prepared beds, &c. and being taken up at the above period of reſt, may be kept out of ground till autumn, or even until ſpring on particular occaſions; though they flower ſtrongeſt when planted again the October or November following.

All the nine ſpecies and reſpective varieties are ſo hardy, as to grow freely in any of the open beds or borders in the full ground; flower and produce ſeed annually, and moſt of them increaſe exceedingly by off-ſets of the root.

With reſpect to their uſe in gardens, all the ſpecies and varieties are proper to be employed as furniture to adorn the open borders and flower-beds; the fine varieties of the Oriental Hyacinth is commonly cultivated in beds by themſelves: the common kinds of them, however, along with the other ſpecies, may alſo be planted in aſſemblage with other hardy bulbous ſpring flowers, in the common borders; diſpoſing all of them towards the front in patches, three or four roots together in each patch, placing them three or four inches deep; in which mode of diſpoſition they will effect a conſpicuous variety in April and May.

*Of the Oriental Kinds.*

But the Oriental Hyacinth, the chief of the Hyacinth tribe for beauty, elegance, and variety, is by floriſts commonly depoſited in beds by themſelves, both for the convenience of viewing them more commodiouſly, and to have occaſional ſhelter from the rigours of winter, and during the time of their bloom; for although they are hardy enough to ſucceed without any protection, yet they being rather of a delicate temperature, by allowing them ſhelter on particular occaſions, they are made to blow much larger and fairer, and the bloom continued longer in beauty; and as the fine varieties poſſeſs a degree of pre-eminence, and often purchaſed at a great price, it is certainly moſt neceſſary to allow them all poſſible aſſiſtance to blow them in perfection.

They are ſold in great variety by all the ſeed dealers. The prices are from three pence per root, up to five or ten pounds, or more; and ſome varieties are in ſuch high eſteem among floriſts, that twenty or thirty pounds is ſometimes given for a ſingle bulb.

The Dutch ſorts are in moſt eſteem; that is, thoſe that are imported annually from Holland, for thoſe people excel all Europe in raiſing the greateſt variety from ſeed, and alſo in blowing them in the greateſt perfection; owing either to ſome ſecret in their mode of culture, or that the nature of their ſoil is peculiarly adapted to the growth of the bulbs; but let that be as it may, great quantities are annually imported from that country by the dealers, and ſold by moſt of the eminent ſeedſmen, who have catalogues of the names of the varieties, and their prices annexed, which are various according to their ſorts.

As many perſons may not have inclination for cultivating the high-rated varieties, there are many of the inferior ſorts that produce very pretty flowers, which may be had at moderate prices, and may be cultivated either in beds, or in the open borders, in common with other hardy bulbous-rooted flowers without any protection, and will blow freely, tho' probably not ſo large and elegant as thoſe fine varieties indulged with the nice management of a profeſſed floriſt, as hereafter mentioned; yet will exhibit a very beautiful bloom, and make ſome of the prettieſt ornaments of the flower-borders.

Having once obtained ſome roots of any of the varieties, you may increaſe your ſtock annually by off-ſets, which they, however, do not yield ſo freely as ſome other bulbs, ſo muſt make the moſt of every one that offers; and they all furniſh plenty of ſeed

every year, by which new varieties may be raiſed, for all the new ſorts are always firſt obtained by that mode of propagation; and each reſpective variety ſo obtained, is afterwards increaſed by off-ſets of the root. The raiſing them, however, from ſeed, is tedious in practice, for the ſeedling bulbs are hardly brought to flower in leſs than four or five years; but as by this means the ſtock may be greatly increaſed, and many new good flowers acquired, it rewards for the toil, in enjoying the pleaſure of ſeeing flowers of one's own raiſing, and the ſtock greatly multiplied either for pleaſure or profit.

The principal properties that conſtitute a good Hyacinth of the Oriental kind, is, the ſtem perfectly upright, of moderate length, and ſo ſtrong and well proportioned, as to ſuſtain the weight of the florets without bending. The florets ſhould be large, ſwelling below, expanded above, and numerous, ten or fifteen at leaſt, but are often twenty or thirty in number, and ſhould be placed equally round the ſtem, the pedicles on which they grow, longer below than above, diminiſhing gradually in length upward, ſo as to repreſent a pyramid, each pedicle ſo robuſt as to ſupport the florets without drooping.

*Propagation and Culture.*

The propagation of all the varieties is by off-ſets from the root, like other bulbous-rooted perennials; ſee BULBUS; and by ſeed, to obtain new varieties, both of which methods of propagation as hereafter directed. We will firſt exhibit their general culture.

With reſpect to the culture of this celebrated ſpecies of Hyacinth and varieties; let it be remarked, that they ſucceed beſt in a light ſoil, and will proſper in any common earth of a garden of that temperature, but delight more particularly in ſandy ground; allow them, however, as light a ſoil as your garden poſſibly affords, in a dry, open, ſunny ſituation, diſtant from the drip of trees, for theſe bulbs, if planted in ſtrong, or very moiſt land are apt to rot in winter, or become diſeaſed; if, therefore, the ſoil of your flower-borders or beds are of a ſtrong heavy quality, that part deſigned principally for Hyacinths, may be meliorated by adding light materials, ſuch as any light ſandy earth, from the ſurface of ſome field, common, or other place, (not out of deep pits) or driſt or ſea-ſand, or any upper ſandy ſoil, or light earthy compoſt; and ſhould the ſoil of the borders, &c. be of a very light, ſharp, ſandy nature, a portion of light, pliable, loamy earth, and neats dung, or well-rotted dung of old hot-beds, will make a fine compoſt for the Hyacinth, being previouſly added long enough for the dung to be converted into mould. After all, if the common earth of the borders is of a moderately light pliable nature, as above obſerved, and has been occaſionally manured with rotten dung, it will ſuit the common ſorts very well without any other preparation than good digging, &c. obſerving, in either caſe, to work the ground well one ſpade deep at leaſt, if the depth of ſoil admits, raiſing the bed or border a little above the general level to avoid copious moiſture, and rake the ſurface ſmooth.

But the floriſts generally prepare a favourite compoſt for their rare kinds of Hyacinths, which is principally this: light ſandy loam, or any ſandy earth from a paſtured field or common, the top ſpit not more than ten or twelve inches deep, of which about one third to one of driſt or ſea-ſand, from the ſurface, and the ſame quantity of rotten neats dung; mixing and caſting the whole in a heap ridge-ways, in ſome dry ſunny expoſure, to lie a year at leaſt, or if two the better. See COMPOSTS. But to the above materials, ſome add alſo a quantity of rotten leaves of trees, thoroughly rotten, tanner's bark, or any perfectly rotten earthy wood, or rotten ſaw-duſt; all of which together greatly improves the compoſition: though as theſe are not always readily obtained, the other compoſt is frequently uſed with great ſucceſs. With either of theſe compoſts a bed is prepared in September, or early in October, four feet wide, and two deep, ſo that a cavity muſt be digged that width and depth, and filled up entirely with the compoſition, ſix inches above the common level to allow for ſettling, leaving it a fortnight or a month to ſettle, and is then ready for the reception of the Hyacinths.

The virtuoſi in theſe plants are careful never to plant the fine ſorts two years together in the ſame bed or earth, for by planting them every year in a freſh bed, or freſh-prepared compoſt, it greatly improves the ſize and beauty of the flowers.

The proper ſeaſon for planting them, is either in October, or firſt fortnight in November, and thoſe then planted, ſhoot early in ſpring, and flower ſtrong at their uſual ſeaſon, April and

and May; but those planted later in autumn, or are continued out of ground till January and February, for a late bloom, will flower weaker and with inferior beauty; so that the principal part should always be planted at the time first mentioned.

If it is designed to plant any of the common, or more ordinary kinds, to adorn the open borders contiguous to principal walks, or lawns near the habitation, to increase the variety in assemblage with other bulbous-rooted spring-flowers, as early tulips, narcissuses, anemonies, ranunculus, &c. they should be disposed towards the front, at about fifteen inches from the edge, in patches of three roots in each, placed four inches deep; and the patches may be from about one yard to three or four distance: here let them stand to take their chance, without any further care, and they will flower in their usual season; and in this mode of disposition will strike the eye most agreeably among the other flowers then in bloom.

But the fine doubles and other valuable varieties are commonly deposited in beds by themselves, as we before observed, for the convenience of affording them occasional protection from inclement weather, these beds should be four feet wide, and well wrought to the depth before mentioned; and if there is any danger of water standing, or much moisture in winter, raise them five or six inches above the general level; but if dry ground two or three inches is sufficient, finishing them gradually rounding in the middle, allowing two-feet-wide alleys between bed and bed. In each bed you may plant four or five rows, lengthways, about nine inches distant in each row, and four or five inches deep: as to the mode of planting, it may either be in drills drawn the above depth, see DRILL-SOWING, &c. or by dibble, or by bedding them in, i. e. with the spade or rake, trimming the earth evenly from off the top of the bed, five inches deep, into the alleys; then draw lines along the surface the above distance, place the roots upon the lines, bottom downwards, nine inches asunder; which being done, cover the roots over with the earth, which was drawn off the bed for that purpose, as evenly as possible, to the proper depth; and as soon as they are planted, in either method, let the surface of the bed be raked smooth, and the work is done.

The bulbs being planted, the next care is to protect the choicest sorts in the beds occasionally, during winter, from severe frost, to ensure the greater success; for although the bulb itself is hardy enough, yet very intense frost is sometimes apt to affect the young new-shot fibres of the root, also the summit of the young advancing flower-bud, and occasion it to blow weaker than it otherwise would; therefore when severe frost sets in, it is easy to guard those in beds; but those disposed about the borders in patches, is not so readily sheltered: but, indeed, they will all blow tolerably well without that precaution. Those in beds, however, may be readily protected by a covering of straw, or any kind of dry strawey litter, three or four inches thick, or may previously arch the beds with hoops, or rods, or with moveable arched frames of open-work, and covered with mats; observing in either mode of covering, to practise it only in severe frosts, for there will be but little danger of moderate frosts penetrating deep enough to do any hurt; nor ever permit the covering to remain a day longer than the severity of the frost continues, the free air being an important article for the welfare of the plants.

Towards spring, when the flower-buds are beginning to appear above ground, the beds of the fine sorts, if intended to allow them all possible protection from inclement weather, should, if not done in winter, be arched over, to be covered every night with mats, particularly at the appearance of sharp frosts, or when there is cold cutting winds, being careful to take them off every morning in mild weather.

In March the flower-stems will advance fast in stature: according as those of the best sorts arrive nearly at their full height, it is proper to support them, by placing a small stick, fifteen or eighteen inches long, down to each plant, being careful not to thrust it into the bulb, and so tye the stems neatly to each stick, whereby the spikes of flowers, which being heavy, would otherwise be borne down by wind or wet, will be preserved in an upright position.

When they arrive to bloom, the curious sorts that are in beds, may be preserved much longer in beauty, by being screened occasionally from the sun and rain, by a sort of awning or umbrella of mats or canvass; observing they should be shaded only from the mid-day sun from about ten to three or four o'clock, and only from excessive rains and boisterous winds, for they should enjoy the morning

and evening ſun, and the benefit of moderate ſhowers; theſe covers are ſometimes contrived like a tent, of width and height enough for company to walk under them to view the flowers, and that the plants may enjoy the benefit of free air; having the ſides to let down and up at pleaſure, like curtains; as alſo the top to draw off occaſionally to admit moderate warm ſhowers; thus may theſe flowers be continued in their fulleſt beauty three or four weeks, and exhibit a fairer bloom than thoſe that are fully expoſed.

After the flowers, however, begin naturally to fade, remove all covering entirely away, that the bulbs and increaſing off-ſets may receive all poſſible benefit from the free air.

After the ſeaſon of flowering is over, the next care is to take up the bulbs, in the floriſts language called, lifting the roots; for the fine ſorts ſhould be taken up at this period, both to ſeparate any off-ſets for encreaſe, and for the benefit of the main bulbs, which will always flower ſtronger than ſuch that are ſuffered to remain two or more years unremoved; ſo always take up the large blowing-roots annually after flowering.

The proper time for this work of lifting the bulbs, is in ſummer, ſoon after they have done flowering, when their leaves begin to turn yellow, as then the bulbs have had nearly their full growth for that ſeaſon; and ſhould by no means remain longer in the ground, as they would be apt to imbibe moiſture, and become ſpongey, and have tendency to rot after removal. Dry weather muſt be choſen, and a trowel, or ſmall ſpade is proper for lifting them, taking them up one and one; and break off the ſtem within an inch or two of its origin, which being thick and very ſucculent, the moiſture thereof might return again into the bulb, to its detriment; then lay them in an airy room, out of the mid-day ſun, to dry off the groſs moiſture gradually, and to ripen the bulbs to a due hardneſs, appearing of a purpliſh tinge, otherwiſe they are apt to rot, being more impatient of humidity than almoſt any other kind of hardy bulbs: but the floriſts generally ripen the choicer kinds of theſe bulbs, after lifting, in a ridge of dry earth in the full air, to promote a more perfect ripeneſs in the whole bulb, as the groſs humidity will be more effectually drawn off by the heat of the ſun, without being expoſed immediately thereto; to do this, part of the earth of the bed where they grew, is directly formed into a low ridge lengthways, roundiſh at top, and both ſides ſloping to caſt off the water; in this ridge place the bulbs, as ſoon as poſſible, bottom downward beſide each other, and cover them with earth an inch or two deep; being thus placed, let them remain about three weeks, during which time, if heavy rains fall, cover the ridge with mats, to keep the earth and roots as dry as poſſible; and thus the ſun's heat through the earth, will evaporate the watery parts of the bulb, and harden it ſo effectually, that no danger of rotting is much to be feared, neither before nor after they are planted again; obſerving, that when the bulbs, by either of the above modes of ripening them, aſſume a bright purple colour, it is notice of maturenes, this colour being peculiar to theſe bulbs, but the more ſtrong and lively the purple tinge appears, denotes the greater perfection.

When the bulbs are, however, properly ripened in either of the above methods, let them be taken up and ſeparated from any off-ſets, well cleared from earth, looſe ſkins, and fibres at bottom; then, after expoſing them an hour or two in the ſun, put them up in boxes ſingly, or upon dry ſhelves out of the ſun, to remain till the ſeaſon for planting them again, obſerving the ſame method as before directed.

Propagation by Off-ſets.—All off-ſets appearing about the main bulbs at the lifting ſeaſon, are to be careſully ſeparated from them, either as ſoon as they are taken up, or after the bulbs have lain to ripen, kept ſeparate, and planted in September or October, in beds by themſelves, in rows ſix inches aſunder, and two or three deep, where let them remain a year or two; then take them up at the proper lifting-ſeaſon in ſummer, and manage as directed for the large blowing roots.

Raiſing them from Seed.—The raiſing theſe bulbs from ſeed, is practiſed by the curious to obtain new varieties, as well as increaſe their ſtock; obſerving, that from the time of ſowing, it will be four or five years before the bulbs will produce flowers; the ſeed ripens in June or July, which may eaſily be ſaved from your own plants, ſuffering ſome of the fineſt ſingles, and half doubles to ſtand to ripen it in perfection.

The proper ſeaſon for ſowing it is September and October; and will come up in ſpring following.

It grows freely in the open ground, in a bed or border of light earth, or if no great quantity is to be ſown, it may be ſowed in pots or boxes, which will be convenient to move occaſionally to different ſituations at different ſeaſons. In either method chuſe light rich earth, make the ſurface ſmooth, ſow the ſeeds evenly, and cover them an inch or an inch and a half deep; if they are ſowed in pots or boxes, let thoſe be plunged to their rims in a dry place, and in November remove them either under a hot-bed frame to have occaſional ſhelter in winter, or cover them at the approach of hard froſt with ſome light dry litter, uſing the ſame precaution alſo to thoſe ſowed in beds, but let them be fully expoſed in all mild weather.

The plants will come up in the ſpring, appearing firſt with very ſmall leaves; keep them very clean from weeds all ſummer, ſift a little earth over the bed in autumn, and in winter uſe the ſame precaution as before; and in the ſecond ſummer, in June, when their leaves begin to decay, take up the young bulbs, to be planted out in nurſery beds, which may be done in Auguſt or September, planting them in ſmall drills two inches deep, having the drills three or four inches aſunder: here let them ſtand two years, ſifting half an inch of earth over the ſurface in autumn, and give occaſional covering in winter: after this they are to be taken up at the uſual lifting-ſeaſon, managed as the other bulbs, and planted in autumn where you deſign they ſhall flower.

*Of the other eight Species.*

The other eight ſpecies and varieties of this genus, Hyacinthus, tho' inferior to the oriental kind, yet conſidered as flowery perennials for embelliſhing the common borders, &c. they effect an agreeable variety, when diſpoſed in little cluſters, in aſſemblage with other low ſpring-flowers: planting them in autumn, any time before Chriſtmas, towards the front, three, four, or five roots in a patch, about three inches deep, and they will all flower in ſpring following. They may be ſuffered to remain unremoved two or three years, when they will be increaſed by off-ſets into large bunches, and ſhould then be taken up at the decay of the flowers and leaves in ſummer, to ſeparate the off-ſets, planting the large roots again in the borders, as before, in autumn; and the very beſt of the off-ſets that you may have occaſion for, may be planted in nurſery-beds for a year or two.

Their propagation is effected plentifully by the off-ſets, as above-mentioned, which all the ſorts produce in great plenty, and which may be taken up every ſecond or third year, when the leaves decay, and the off-ſets ſeparated and managed as above directed.

HYDRANGEA, *Hydrangea.*

There is but one ſpecies, a ſhrubby deciduous plant, three or four feet high, for the ſhrubbery, having merit for the variety of its large ſimple foliage, and bunches of quinquepetalous flowers.

Claſs and order, *Decandria Digynia.*

*Characters.*] CALIX, is monophyllous, and five-parted at top. COROLLA, five roundiſh petals. STAMINA, ten filaments, alternately longer than each other, and roundiſh didymous antheræ. PISTILLUM, a roundiſh germen under the corolla, two ſhort ſtyles, and obtuſe ſtigmas. PERICARPIUM, a roundiſh didymous bilocular capſule, crowned by the permanent ſtyles, like two horns, and contains numerous ſmall angular ſeeds.

The ſpecies is;

*Hydrangea Arboreſcens.*] Hath a fibrous very ſpreading root; ſending up ſeveral ſhrubby, thick, pithy, perennial ſtalks, three or four feet high; garniſhed at each joint with largiſh, heart ſhaped, ſerrated, oppoſite leaves, on long foot-ſtalks; and large cymoſe bunches of white flowers at the top of the ſtalks.

It is a native of North America, is very hardy, and flowers here in July and Auguſt, but rarely produces good ſeeds in England.

The propagation of this ſpecies is very eaſy, for its ſpreading roots ſending up many ſtalks, they may be ſlipped off with great facility in autumn or ſpring, with roots to each, and may be planted in the ſhrubbery to remain, or in nurſery rows as may be convenient.

HYPERICUM, St. John's-Wort.

This genera furniſhes ſeveral hardy deciduous ſhrubs and underſhrubby plants for the ſhrubbery; and ſome tender ſhrubby exotics for the green houſe; all of them adorned with oblong and oval ſimple foliage, and pentapetalous yellow flowers in cluſters.

Claſs and order, *Polyadelphia Polyandria.*

*Characters.*] CALIX, is divided into five oval, permanent ſegments. COROLLA, five oblong oval ſpreading petals. STAMINA, numerous

numerous filaments, joined in ſeveral bodies and ſmall antheræ. PISTILLUM, a roundiſh germen, from one to three or five ſtyles, but moſt commonly three, and ſimple ſtigmas. PERICARPIUM, a roundiſh capſule, of as many cells as there are ſtyles, and numerous oblong ſeeds.

There are about ſix or ſeven ſpecies commonly retained in the Engliſh gardens as plants of ornament, four of them hardy, and three tender.

*Hardy Kinds.*

[1]HYPERICUM *Hircinum.*

*Stinking St. John's-Wort.*] Hypericum with ſeveral ſhrubby, two-edged ſtalks from the root, three or four feet high, branching by pairs oppoſite at every joint; oblong-oval, cloſe-ſitting, oppoſite leaves; and at the ends of all the young ſhoots, cluſters of yellow flowers, having the ſtamina longer than the petals, and three ſtyles.

The whole plant has a ſtrong diſagreeable odour.

*Varieties.*] Stinking St. John's wort, with ſtrong ſtalks, ſix or eight feet high, broad leaves, and large flowers——inodorous St. John's-wort, with ſtrong ſtalks, broad leaves, and without any diſagreeable odour——with variegated leaves.

All theſe varieties are ſhrubby, flower in June and July, in ſuch numerous cluſters, that the ſhrubs appear covered with them, and produce abundance of ſeed in autumn.

[2]HYPERICUM *Canarienſis.*

*Canary St. John's-Wort.*] Hath ſhrubby ſtalks, dividing and branching ſix or ſeven feet high, oblong, cloſe-ſitting leaves, by pairs; and at the ends of the branches, cluſters of yellow flowers, having the ſtamina longer than the corolla, and three ſtyles; flowering in June and July.

[3]HYPERICUM *Aſcyron.*

*Aſcyron, or Dwarf American St. John's-Wort.*] Hath very ſpreading roots, ſending up numerous, ſlender, four-ſquare ſtalks, a foot long; oval, ſpear-ſhaped, cloſe-ſitting, ſmooth leaves, by pairs oppoſite; and at the ends of the ſtalks, large yellow flowers, having five ſtyles.

[4]HYPERICUM *Androſæmum.*

*Androſæmum, commonly called Tutſan, or Park-leaves.*] Hath an upright under-ſhrubby ſtalk, two feet high, branching by pairs oppoſite; oval, heart-ſhaped, cloſe-ſitting leaves, by pairs; and from the tops of the ſtalks, cluſters of ſmall yellow flowers, having three ſtyles; and roundiſh berry-like black capſules; flowers in the end of July and Auguſt.

It grows naturally in woods in many parts of England, &c.

*Tender Green-houſe Kinds.*

[5]HYPERICUM *Balearicum.*

*Balearic warted-leaved Hypericum.*] Hath a ſhrubby ſtalk, branching two feet high, with reddiſh ſcarrified branches; ſmall, oval, waved, cloſe-ſitting, ſemi-amplexicaule leaves, warted underneath, and large yellow flowers, having five ſtyles; flowering great part of the year. Is a native of Majorca.

[6]HYPERICUM *Monogynum.*

*Monogynous, or One-ſtyled China Hypericum.*] Hath ſhrubby purpliſh ſtalks, about two feet high; oblong, ſtiff, ſmooth, cloſe-ſitting leaves, of a ſhining green above, and white underneath, and cluſters of ſmall yellow flowers, with coloured cups, and only one ſtyle; flowering moſt part of the year.

[7]HYPERICUM *Laſianthus.*

*Laſianthus, or Surinam Hypericum.*] Hath ſhrubby ſtalks, branching a yard high; ſpear-ſhaped ſerrated leaves, hoary underneath; and from the axillas of the ſtalks, yellow flowers, having five ſtyles. Is a native of Surinam and Carolina.

The flowers of all theſe ſpecies of Hypericum conſiſt each of five oblong oval petals, numerous ſtamina, and from one to five ſtyles (ſee the *Characters*); appearing principally in June, July, and Auguſt, and ſome moſt part of the year, in numerous cluſters, moſtly from the ends of the branches and young ſhoots, ſucceeded by oval capſules, containing plenty of ſeeds in autumn, eſpecially in the hardy kinds.

All the ſpecies demand attention as plants of ornament, having great merit in their flowers, appearing very conſpicuous in long ſucceſſion.

The hardy kinds are good furniture for all the ſhrubbery compartments, and will grow in any ſituation and expoſure, and in any common ſoil of a garden, will endure the ſevereſt cold, and greatly ornament the ſhrubbery in ſummer; more particularly the firſt and ſecond ſorts and varieties, which are more of a ſhrubby durable growth, than the other two hardy kinds; but all the ſorts merit culture to increaſe the variety. All of which are ſold cheap enough at the nurſeries, and may

may be eaſily increaſed by ſuckers, by ſlips of the root, and by ſeed. See their *Propation.*

The three tender ſpecies being natives of warm countries, muſt be potted to have ſhelter in winter in the green-houſe, and will effect a pretty variety among the other tender exotics.

*Propagation, &c. of all the Sorts.*

The firſt two hardy ſorts propagate very faſt by ſuckers, from the root, which are ſent up plentifully every year; and in autumn or ſpring may be readily ſlipped off from the old plants, with roots to each, or the whole plant may be taken up and divided into as many parts as there are ſuckers and ſlips with roots, planting the ſtrongeſt where they are to remain, and the weakeſt in nurſery rows for a year to acquire ſtrength.

They may alſo be propagated by ſeeds, ſowed in autumn in a bed of common earth, in drills an inch deep; the plants will riſe plentifully in ſpring, and be fit to tranſplant the ſpring following.

The other hardy ſorts are alſo eaſily propagated by ſlipping the roots in autumn, or early in ſpring; and may likewiſe be raiſed in great plenty by ſeeds as directed for the two former.

The three tender ſpecies are propagated by layers, and by cuttings. The laying is performed in ſpring on the young ſhoots, which will be well rooted by the end of ſummer; then plant each in ſeparate pots. And cuttings of the young ſhoots may be planted any time from March till June, in pots, and plunged in a hot-bed; they will readily emit roots and form plants.

The Monogynous Hypericum may likewiſe be propagated by ſlipping the roots in ſpring.

Theſe ſorts may alſo be raiſed from ſeed ſowed in ſpring, in pots, and plunged in a hot-bed, juſt to bring up the plants.

HYPERICUM *Frutex.* See SPIRÆA, it being a ſpecies of that genus.

HYSSOPUS, Hyſſop.

The Hyſſop of our gardens is a low undershrubby perennial, a fine aromatic, and medical plant.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, is monophyllous, oblong, five-parted, and permanent. COROLLA, is monopetalous and ringent, having the upper lip plane, roundiſh, emarginated and erect; the under one trifid, with the middle ſegment long and acute, and the ſide ones ſhort and obtuſe. STAMINA, two long and two ſhort filaments, and ſimple antheræ. PISTILLUM, a four-parted germen, ſlender ſtyle, and bifid ſtigma. PERICARPIUM, none, four oval ſeeds lodged in the calix.

There are three diſtinct ſpecies, but not more than one commonly cultivated, viz.

HYSSOPUS *Officinalis.*

*Officinal, or Common Hyſſop.*] Hath undershrubby, low, buſhy ſtalks, growing a foot and a half high; ſmall ſpear-ſhaped, cloſe-ſitting, oppoſite leaves, having ſeveral ſmaller riſing from the ſame joint; and all the ſtalks and branches terminated by erect, whorled ſpikes of flowers, of different colours in the varieties.

*Varieties.*] Common blue-flowered—white-flowered—red-flowered—long ſpiked with deep blue flowers—curled-leaved—ſtriped-leaved.

All theſe varieties are undershrubby, having ligneous durable ſtalks and branches, and all produce numerous ſmall flowers in whorls round the upper part of the ſtalks for a great length: each flower is of one petal, of the ringent or grinning kind.

They are very hardy plants, of great eſtimation as aromatics for medical purpoſes, and the common blue-flowered kind is the ſort chiefly uſed; and which is generally cultivated in the kitchen garden, ſometimes in cloſe rows, by way of edgings to beds or borders, clipping them annually to keep them regular and within due compaſs; ſee EDGINGS: and ſometimes are diſpoſed in beds, &c. in rows fifteen or eighteen inches aſunder, and the ſame diſtance between the plants in each row. The young ſhoots are the parts proper for uſe, and may be cut any time when wanted: obſerving, however, their ſeaſon of perfection for any general uſe, is in ſummer, when they are in flower; at which time the flower-ſtalks ſhould be cut down for uſe, and tied in bunches.

But all the varieties may alſo be employed to adorn the borders, and other parts of the pleaſure-garden, diſpoſing them here and there ſingly to form buſhy plants.

Their propagation is by ſeed, by ſlips, and by cuttings.

By Seed.—In March or April ſow the ſeed in a bed or border of light earth, and rake it

it in; and when the plants are come up, thin them, if too close, and when about three or four inches high, plant them out where they are to remain; or when it is designed to form an edging of them, the seed may be sown at once where the plants are to remain, in small drills, and covered half an inch deep.

By Slips and Cuttings.—In March, April, or May, slip or cut off a quantity of the robust side-shoots, plant them in a shady border, five or six inches apart; give water as soon as planted, repeat it occasionally, and they will soon strike root, and in autumn may be planted out where they are always to stand.

---

# J.

JASMINUM, Jasmine, or Jessamine-tree.

The plants are of the shrub kind, mostly of somewhat trailing growth, consisting of three hardy deciduous flowering-shrubs for the open ground, and three tender ever-green flowering-shrubs for the green-house, adorned with pinnated and trifoliate leaves, and numerous monopetalous, tubular, five-parted flowers, which, in most of the species, are of admirable fragrance.

Class and order, *Diandria Monogynia*.

*Characters.*] CALIX, is monophyllous, tubulous, five-parted at the brim, and permanent. COROLLA, is monopetalous, with a long cylindric tube, and with the limb or upper part divided into five segments. STAMINA, two short filaments, and small antheræ. PISTILLUM, a roundish germen, slender style, and bifid stigma. PERICARPIUM, an oval bilocular berry, and two large oval seeds.

*Hardy Deciduous Kinds.*

[1]JASMINUM *Officinale.*

*Common White Jasmine.*] Jasminum, with shrubby, long, slender stalks and branches, rising upon support fifteen or twenty feet high; pinnated opposite leaves, of about three pair of sharp-pointed folioles, terminated by an odd one, running out to a long point, and numerous white flowers from the joints and ends of the branches; of a very fragrant odour.

*Varieties.*] With white striped leaves—yellow striped leaves.

All three varieties flower in great profusion most part of the summer; the flowers are universally white, and remarkable for their great fragrance; but are never succeeded by fruit in England.

[2]JASMINUM *Fruticans.*

*Shrubby Yellow Jasmine.*] Hath shrubby, angular, trailing stalks and branches, rising upon support eight or ten feet high; trifoliate and simple alternate leaves; and yellow flowers from the sides and ends of the young branches, appearing in June; frequently producing berries of a black colour.

This species is remarkable for sending up many suckers from its roots, often so plentifully as to over-spread the ground, if not taken up annually.

[3]JASMINUM *Humile.*

*Dwarf Yellow Jasmine.*] Hath shrubby firm stalks, and angular branches, of low, somewhat robust, bushy growth; broad trifoliate and pinnated leaves; and large yellow flowers in July, sometimes succeeded by berries.

The above three species are natives originally of distant countries; the first of India, the others of the southern parts of Europe, but are all hardy enough to grow here in the open ground, and have been many years inhabitants of our gardens.

*Tender Green-house Kinds.*

The following three species are natives of different parts of India, but succeed here with only protection from frost, and will sometimes live in the open air all the year, against

againſt a warm wall; it is, however, proper always to keep the principal part in pots to move to a green-houſe in winter.

[4]JASMINUM *Grandiflorum*

*Great-flowered Catalonian Jaſmine.*] Hath a ſhrubby, firm, upright ſtem, branching out into a ſpreading head, from about three to ſix or eight feet high; pinnated ever-green leaves, of three pair of pointed lobes, terminated by an odd one; and large flowers, of a bluſh red without, and white within; flowering from July till November.

*Variety.*] With ſemi-double flowers, having two ſeries of petals.

[5]JASMINUM *Azoricum.*

*Azorian White Jaſmine.*] Hath ſhrubby, long, ſlender ſtalks and branches, riſing upon ſupport fifteen or twenty feet high; trifoliate, oppoſite, ever-green leaves; and largiſh pure white flowers, in looſe bunches from the ends of the branches, appearing moſt part of ſummer and autumn.

[6]JASMINUM *Odoratiſſimum.*

*Odoriferous, or moſt Sweet-ſcented Yellow Indian Jaſmine.*] Hath a ſhrubby upright ſtalk, branching erectly without ſupport ſix or eight feet high, large trifoliate, ſhining, alternate, ever-green leaves, having oval lobes, and the middle lobe the largeſt; and bright yellow flowers in bunches from the ends of the branches; flowering from July till October, and emits a moſt fragrant odour.

Moſt of the above ſpecies of Jaſminum have long, ſlender, declinated branches, producing many very long, weak, green, pithy ſhoots annually, and from which the flowers are commonly produced.

The flowers of all the ſorts conſiſts of one petal, long and tubular below, and divided at top into five ſpreading ſegments. See the *Characters.*

*Culture of the Hardy Kinds.*

The three hardy kinds are proper furniture to adorn the pleaſure-garden; but their branches being moſtly long, ſlender, and of declinated growth, require ſupport, eſpecially the *Jaſminum Officinalis*, which is moſt commonly planted againſt walls and other fences, both for the convenience of training them, and to ornament the places, with their profuſion of flowers in ſummer. But this and the other two hardy kinds, may alſo be ſtationed in ſhrubberies, training them with upright ſingle ſtems, half a yard or a yard high, to ſtakes; and as they will branch out each way, by trimming the long ſtraggling ſhoots occaſionally every ſpring and ſummer, they may be made to form buſhy heads: thoſe planted againſt fences, ſhould be pruned down low at firſt, to force out lower lateral ſhoots, ſo as to furniſh every part from the bottom upward, and every year a due quantity of the ſtrongeſt ſhoots in every part are to be trained in, cloſe to the wall, &c. previouſly ſhortening them, more or leſs according to their ſtrength; but always cut low enough to take off the weak ſtraggling ſoft parts, and nail them in ſtraight, about four inches apart; and as, in ſummer, numerous ſhoots are ſent forth from all the branches, and that from the upper parts of the ſmaller ſhoots, the flowers generally ariſe; ſo that at this ſeaſon the rudeſt growing ſhoots may be reduced to a regularity, either by knife or garden-ſhears; obſerving, however, not to clip too cloſe, to cut off the parts that produce the flowers; but knife pruning is moſt eligible, by which you may train the whole always regular at the above diſtance, like a wall-tree; in ſummer, cutting out all the moſt irregular rambling ſhoots, and train a due quantity of the principal ones cloſe to the wall, to remain till winter or ſpring pruning; then ſelecting ſome of the ſtrongeſt in different parts to be trained as above hinted; at the ſame time cutting out all the ſuperabundant and weak ſhoots, cloſe to the old wood, ſo as to preſerve all the branches diſtinct at regular diſtances, in the manner of a wall-tree; being careful always to leave every year ſome of the ſtrongeſt young ſhoots at proper intervals, quite from the bottom to the top, to furniſh flowers in every part, and to ſupply the place of any decayed, or old naked wood, which ſhould be cut away occaſionally in the winter or ſpring pruning, and its place ſupplied with young ſhoots.

*Culture of the Tender Kinds.*

The three tender ſpecies requiring ſhelter of a green-houſe in winter, muſt always be kept in pots, to move them in and out occaſionally; let them be potted in rich light earth, frequently watered in ſummer, and about once a week in winter, but always moderately during that ſeaſon; prune off all decayed wood, at any time when it appears; and ſhorten, or retrench the rambling ſhoots as you ſhall ſee occaſion, to preſerve the heads ſomewhat regular, managing them in other reſpects as directed for other green-houſe ſhrubs. See GREEN-HOUSE PLANTS.

A plant or two of each of theſe tender ſpecies may alſo be planted againſt a warm wall, trained thereto, and left to take their chance, with only occaſional ſhelter of mats in froſty weather.

*Propagation of all the Sorts.*

The three hardy ſorts are eaſily propagated in great plenty by layers and cuttings. Lay a quantity of the ſtrong young ſhoots in autumn, winter, or ſpring, trimming their tops, and they will be well rooted by autumn following: at the ſame ſeaſons cuttings of the ſtrong ſhoots, in lengths of ten or twelve inches, planted in a ſhady border, will be rooted and fit to tranſplant by next autumn. The *Jaſminum Fruticum* may alſo be propagated by ſuckers, which it ſends up in great plenty, and theſe being taken off will make good plants.

The ſtriped varieties of the firſt ſpecies are alſo propagated by grafting or budding in ſtocks of the common kind.

The three tender ſpecies may alſo be encreaſed by layers in March: chuſing the young wood, make a ſlit at a joint in each layer, where they are to be layed, and lay them in the uſual way; give plenty of water all ſummer: they will be properly rooted by autumn, when each layer is to be ſeparated from the parent, and planted ſingly in pots, and placed among the other green-houſe exotics.

Theſe three kinds are alſo very commonly propagated by grafting, and budding them upon the common white, and ſhrubby yellow Jaſmine.

They are alſo raiſed from ſeeds, more particularly the Azorian Jaſmine, and *Jaſminum Odoratiſſimum*. Sow the ſeed in March or April, in pots of light rich earth, an inch deep, and plunge the pots in the earth of a moderate hot-bed under frame and glaſſes; refreſh them with frequent ſprinklings of water, and the plants will riſe in five or ſix weeks, or in a little more or leſs time, when freſh air muſt be admitted daily, by tilting the lights, giving alſo frequent waterings; and towards the middle or latter end of May, begin to inure them to the full air, and remove them into it fully in June, to remain till October, then moved into the green-houſe for the winter; and in March or April following, tranſplant them into ſeparate ſmall pots, and managed as other green-houſe ſhrubs.

JATROPHA, Caſſada, or Caſſava-plant, &c.

This genus furniſhes ſhrubby, elegant, flowery perennials, natives of the warm parts of America, and retained here in hot-houſes for variety; growing with durable ſtems and branches, erect, from about a yard to eight or ten feet high; adorned with divided palmated leaves; and monoecious, monopetalous hypocrateriforme males, and quinquepetalous female flowers.

Claſs and order, *Monoecia Monadelphia.*

*Characters.*] CALIX, monoecious flowers, having a very ſmall cup to the males, and none to the females. COROLLA, is, in the males, monopetalous, hypocrateriforme, five-parted and ſpreading; and, in the females, conſiſts of five roſe-like petals. STAMINA, in the males, ten erect united filaments, five of them alternately ſhorter, and roundiſh verſatile antheræ. PISTILLUM, a roundiſh triſulcated germen, three forked ſtyles, and ſimple ſtigmas. PERICARPIUM, a roundiſh, trilocular, tricoecous capſule, and three roundiſh ſeeds.

There are ſeveral ſpecies, of which the following are thoſe generally retained here in our hot-houſes.

1 JATROPHA *Manihot.*

*Manihot, or eſculent Jatropha, commonly called Caſſada, or Caſſava.*] Jatropha, with a thick fleſhy root; an upright, thick, woody, pithy ſtalk, riſing ſix or ſeven feet high; palmated leaves, of ſeven ſpear-ſhaped, ſmooth, entire lobes, five or ſix inches long, all uniting at their baſe, and ſpread out like an expanded hand; and male and female yellow flowers in umbels at the top of the ſtalk and branches, ſucceeded by three-furrowed capſules containing the ſeeds.

The root of this ſhrub, though of a poiſonous quality, ſerves for bread to moſt of the inhabitants of the Weſt-Indies, being firſt diveſted of its poiſonous juice by expreſſion; it is prepared by rubbing the root forcibly upon a ſtrong copper grater, till reduced to a rough ſaw-duſt-like powder, or meal, is then put into a preſs, to ſqueeze out the poiſonous juice; and being ſufficiently preſſed and ſifted, is made into bread, by ſpreading it two or three inches thick, upon an iron plate heated over a fire, and thus the parts join, incorporate, and become cake bread, which is accounted very nouriſhing; and if the meal is put into ſoup, it ſwells up conſider-

ably,

ably, which ſeems to prove its great abundance in ſubſtance.

Great quantities of this ſort are cultivated in all the Weſt-India iſlands for the above purpoſes.

[2]JATROPHA *Urens.*

*Stinging Jatropha*] Jatropha with a thick fleſhy root; an upright, ligneous, prickly, pithy ſtalk and branches, riſing five or ſix feet high; palmated leaves, of five ſinuated lobes, armed with ſtinging ſpines; and white flowers in umbels from the ends of branches.

[3]JATROPHA *Goſſypifolia.*

*Goſſypium-leaved Jatropha.*] Hath a woody, branchy ſtalk, riſing four or five feet high, ſet with cluſters of briſtly hairs; leaves divided into oval, entire lobes; and dark purple flowers growing in umbels at the ends of the branches.

JATROPHA *Multifida.*

*Multifid Jatropha.*] Hath a thick, woody, pithy ſtalk, branching eight or ten feet high; large many-lobed leaves, having the lobes multifid or jagged into many points; and bright ſcarlet flowers, growing in umbels at the ends of the branches.

All theſe ſpecies of Jatropha are durable in root, ſtalk, and branches; the ſtalks are woody, generally very thick, ſomewhat ſucculent, and full of a white pith and milky juice; the leaves very large and elegant; and the flowers produced in large umbels, having male and female in the ſame umbel; the males are of one ſalver-ſhaped petal, and the females are of five petals, expanding in form of a ſingle roſe; they flower here annually in ſummer, and are frequently ſucceeded by ripe ſeeds, which are contained in roundiſh three-lobed capſules of three cells, having one ſeed in each cell.

As all the ſorts are natives of the warmeſt parts of the world, they require a hot-houſe to preſerve them in this country, ſo muſt be potted in pots of good light-earth, and always continued in the ſtove, where they will exhibit a fine variety with their large elegant foliage, and umbellate flowers.

They ſhould be always but moderately watered, eſpecially in winter, for being moſtly replete with a milky juice, much moiſture might rot them.

Their propagation may be performed by ſeed, and cuttings.

By Seed.—The ſeed frequently ripens here, and is alſo imported annually from America, which ſhould be ſowed in ſpring, in pots of rich light earth, and plunged in the bark-bed, where the plants will ſoon come up; and when a few inches high, prick them in ſeparate ſmall pots, give a little water, and plunge them alſo in the bark-bed.

By Cuttings.—In ſpring or ſummer, cuttings of the ſtalks and branches, ſix or eight inches long, planted in pots, and plunged in the bark-bed, will put out roots, and become proper plants. This is the common method of propagating the firſt ſort in America for food.

IBERIS, Candy-tuft, or Sciatica Creſs.

This genus comprehends hardy, herbaceous, low, flowery annuals for the borders, and under-ſhrubby perennials for the green-houſe; all of them of branchy buſhy growth, from about ſix or eight inches to a foot and a half high; garniſhed with narrow entire leaves, and terminated by umbels of tetrapetalous flowers.

Claſs and order, *Tetradynamia Siliculoſa.*

*Characters.*] CALIX, four ſmall oval deciduous leaves. COROLLA, four oval, ſpreading, unequal petals, the two outer ones longeſt. STAMINA, four long and two ſhort filaments, and roundiſh antheræ. PISTILLUM, a roundiſh compreſſed germen, ſhort ſtyle, and obtuſe ſtigma. PERICARPIUM, a roundiſh compreſſed bilocular capſule, and two oval ſeeds.

The ſpecies cultivated in our gardens are, two hardy herbaceous annuals, and two or three tender ſhrubby perennials.

*Hardy Herbaceous Annual Kinds.*

[1]IBERIS *Umbellata.*

*Umbellated Iberis, or Common Candy-Tuft.*] Iberis, with herbaceous, ſhort, round, very branchy ſtalks, of tufty growth, from about ſix to eight or ten inches high; ſmall ſpear-ſhaped leaves, the lower ones ſerrated, the upper entire; and all the ſtalks and branches terminated by umbellate cluſters of flowers of different colours in the varieties.

*Varieties.*] With white flowers—with red flowers—and with purple flowers.

All the varieties flower in June, and by different ſowings may be made to flower to the end of ſummer; they were introduced to our gardens from Candia.

[2]IBERIS *amara.*

*Bitter Candy-Tuft.*] Hath herbaceous, ſhort, round, very branchy ſtalks, of buſhy growth, from about eight to ten or

twelve inches high; ſmall, ſpear-ſhaped, ſlightly-indented leaves; and all the branches terminated by racemoſe bunches of white flowers in June and July, &c.

Both theſe ſpecies and varieties are very hardy annual flowers, riſe freely in the open ground, ſhould generally be ſowed in patches, and by different ſowings from March till Midſummer, they will afford a ſucceſſion of bloom from June till September, and produce great plenty of ſeeds.

*Shrubby Perennial Kinds for the Green-houſe.*

The two following low under-ſhrubby ſpecies being natives of Candia, and other warm parts, require ſhelter of a green-houſe here in winter.

3 IBERIS *Sempervirens.*

*Ever-green Shrubby Iberis, commonly called Tree Candy-Tuft.*] Hath low under-ſhrubby ſtalks, very branchy and buſhy, growing but ten or twelve inches high; very narrow acute entire leaves, remaining all the year; and white flowers in umbels at the ends of the branches, appearing great part of the ſummer.

* IBERIS *Semperflorens.*

*Ever-flowering Shrubby Iberis.*] Hath low under ſhrubby ſtalks, very branchy, ſpreading and buſhy, growing a foot and a half high; wedge-ſhaped, obtuſe, entire, ever-green leaves; and white flowers in umbels, at the ends of the branches, appearing at all times of the year.

*Variety.*] With white ſtriped leaves.

The flowers of all theſe plants conſiſt each of four ſmall petals, are very numerous, terminating all the branches in umbellate cluſters, ſo conſpicuouſly, that the plants appear covered therewith; ſucceeded by abundance of ſeed in the annual ſorts; but the ſhrubby kinds rarely produce any here.

The two annual ſpecies make a pretty appearance when diſpoſed in patches in the flower-borders, ſowed in ſpring where they are finally to remain; but as they continue only two or three weeks in beauty, it is proper to perform three or four different ſowings from Feb. or March until June, to have a ſucceſſion of bloom to the end of ſummer. Sow about half a thimbleful of ſeed in each patch of about five or ſix inches diameter, covering them with fine earth, near half an inch deep; and when the plants are an inch high, thin them to about ſix in each patch, that they may have room to branch and ſpread, where by they will flower ſtronger, and continue longer in bloom, than if left thick.

The two ſhrubby perennial kinds, are naturally of low buſhy growth, durable in root, ſtem, and branches, ever-green, and very floriferous, and merit admittance in every green-houſe collection, both as ever-greens, and for the beauty of their flowers almoſt throughout the year. They being impatient of froſt, muſt be potted to move to ſhelter in winter; potting them in any good light earth, and place them in a green-houſe or garden-frame in winter. A few plants of each may alſo be planted in the full ground, in a dry ſheltered ſunny ſituation to take their chance, and will frequently ſtand tolerably well the year round, with only a light covering of long ſtrawey litter in hard froſts.

The propagation of theſe two ſhrubby kinds and variety, is eaſily effected by ſlips and cuttings, from three to five or ſix inches long, planted any time from March till July, either in a hot bed or natural earth, affording them ſhade and water, and they will readily put out roots, and be fit for potting towards the end of ſummer.

ICE-HOUSE, a building ſunk in the ground, ſerving as a repoſitory to preſerve Ice till ſummer, for various family-uſes; the management of which generally belongs to the gardener.

This building is conſtructed like a well, moſtly ſunk in the ground as above obſerved, eight, ten, or twelve feet deep, walled with brick or ſtone, arched over at top, having a ſmall door on the north-ſide, and over all a ſlated or thatched roof. The place for this building ſhould be generally in ſome bye part of the garden, or ſome convenient place contiguous thereto: chuſing a dry elevated ſituation, both that the Ice may not be liable to be melted by copious moiſture, and that all moiſture running from the Ice may readily drain off. It would be of much advantage if it could be contrived on or near the ſide of ſome hill, or ſloping ground, where the baſe of the ſlope is lower than the bottom of the well of the building, for the more effectually draining off the moiſture; let it, however, be contrived in as dry a place as poſſible, and ſo much elevated as the water may be eaſily carried off by drains to ſome lower ground; and ſhould be in a part either within, or contiguous to the garden, where carts can readily bring in the Ice in winter.

The

The place being fixed on, a well muſt be digged, eight or ten feet diameter, and as much in depth, or more; obſerving, if the ſituation fixed on is ſomewhat elevated, and the ground of a dry gravelly, or ſandy nature, not retentive of moiſture, the pit or well may be wholly ſunk below the general ſurface; but if rather low, or moiſt ground, it is adviſable to have the well raiſed as much above the ſurface as the moiſture may eaſily drain away. Having formed the cavity or pit of the well, then at bottom ſhould be formed a hollow ſpace for a drain, two feet deep, the ſides walled with brick or ſtone, having at top a grate framed with ſtrong wooden bars; from the bottom of this drain muſt be a ſmall under-ground drain, to conduct the moiſture quite away from the building. The ſides of the main well muſt be walled round with brick or ſtone, two feet thick at leaſt, and carried up to a proper height, leaving, near the top, on the north ſide, a ſpace two feet and a half diameter, for the admiſſion of the Ice, &c. and terminate the wall all round with a ſtrong thick arch of the ſame materials carried over the top; and there ſhould be another wall proceeding from within three feet below the top of the other, raiſing it alſo with an arch over the top of the firſt, leaving likewiſe a place for entrance; or, if this outer wall is not arched, raiſe upon it a wooden roof ſlated, tyled, or thickly thatched; obſerving if ſlated or tyled, a foot thickneſs of reeds or ſtraw under it is proper, the better to exclude all air and heat of the ſun; and from the door or mouth of the well, ſhould be a porch continued a yard and a half outward, and one or two wide, walled on the ſides, and arched at top, and a door at the outer end; and both the inner and outer doors made to ſhut perfectly cloſe. The building thus far advanced, may then bank up earth around the out-ſide wall, the better to defend the Ice from all external cauſes, and finiſh with a coat of turf laid neatly all over the banking.

If the building is finiſhed betimes in the ſummer, it will be dried enough for the reception of the Ice the following winter.

Therefore in winter take the opportunity of the firſt Ice, when about an inch or two thick; load it in carts, and bring it to the Ice houſe, ſhooting it down at the outer door; then, after having laid ſome clean ſtraw, reeds or faggots of bruſh wood at the bottom of the well upon the wooden grate, caſt in the Ice, breaking it ſmall, and ramming it cloſe from time to time, that it may cement into one ſolid maſs; obſerving, as you proceed, to lay ſome clean ſtraw all round next the wall if poſſible, to preſerve a vacancy to give paſſage to any moiſture that may proceed from the top of the Ice.

As ſoon as the well is thus filled with Ice, ſhut the inner door, which ſhould be thick, cloſe, and made to fit exactly; then let all the vacant ſpace between that and the outer door be cloſely filled with ſtraw, and then ſhut the outer door as cloſe as poſſible.

Thus the Ice will be preſerved till ſummer; and if the houſe is perfectly air and moiſture tight, will keep two or three years.

When the ice is to be taken out for uſe, be careful, in going in, always to ſhut the outer door before the inner one is opened; and as the ice will be all incorporated to a ſolid lump, you muſt have an iron inſtrument always in readineſs to break it up, taking out no more at a time than is wanted.

ILEX, (formerly *Aquifolium*) the Holly-tree.

This genus furniſhes hardy ever-green trees of great beauty and value, being proper both for uſeful and ornamental plantations; obtain twenty or thirty feet ſtature, adorned with long ſpinous, and ſerrated ever-green leaves, and ſhort cluſters of monopetalous four-parted flowers, ſucceeded by bunches of beautiful red berries in autumn and winter.

Claſs and order, *Tetrandia Tetragynia.*

*Characters.*] CALIX, is ſmall, indented in four parts, and permanent. COROLLA, is monopetalous, and deeply divided into four roundiſh ſegments. STAMINA, four ſhort filaments, and ſmall antheræ. PISTILLUM, a roundiſh germen, no ſtyle, but four obtuſe ſtigmas. PERICARPIUM, a roundiſh quadrilocular berry, and four oblong hard ſeeds.

There are but two ſpecies of *Ilex* common to the Engliſh gardens:—the common Holly—and Dahoon Holly; but of the former are many fine varieties.

The ſpecies are;

1 ILEX *Aquifolium.*

*Aquifolium, or Common Holly-tree.*] Hath an upright trunk, branching all around, twenty or thirty feet high, in a conic form; oval, waved, ſtiff, alternate leaves, having the edges and extremity terminated by ſharp ſpines, pointing ſome upward, and ſome downward; and from the ſides of the branches

branches, ſmall whitiſh flowers in ſhort cluſters, appearing in May; ſucceeded by bunches of roundiſh berries, ripening to a beautiful red colour in autumn and winter. Is a native of woods and foreſts in England.

Of this ſpecies are many curious varieties, both with entire green leaves, and with variegated, but the variegated kinds are the moſt extenſive.

*Green-leaved Varieties.*] Common green-leaved, prickly Holly—ſmooth green Holly, the leaves being deſtitute of ſpines—narrow, ſerrated-leaved green Holly—green-leaved, yellow-berried Holly—box-leaved green Holly—hedge-hog green Holly, having the ſurface of the leaves cloſely ſet with ſmall prickles, reſembling thoſe of a hedge-hog; hence it derived the name, (*Ilex Echinata.*)

*Variegated ſorts.*] Common prickly Holly, with ſilver-ſtriped leaves——with gold-ſtriped leaves—with bloatched leaves—ſmooth Holly with white-ſtriped leaves——yellow-ſtriped leaves—with bloatched leaves—narrow ſtriped-leaved Holly—bloatched-leaved, yellow-berried Holly—cream-coloured Holly—copper-coloured Holly—white-leaved Holly—mottled Holly—hedge-hog ſilver-edged Holly—gold-edged hedge-hog Holly—white bloatched hedge-hog Holly—yellow bloatched hedge-hog Holly—painted lady variegated Holly.

There are many other varieties of the variegated Holly, differing a little in the ſize, form, and variegation of the leaves, and are retained in moſt of the nurſeries, and named in their catalogues, often by that of the perſons who raiſed them, or any name according to their fancy; but the ſorts above mentioned being the principal varieties, moſt of the others belong to one or other of them.

All the varieties, both green and variegated kinds, are hardy ever-greens, of the tree and ſhrub kind, branching out every way from the bottom upward, and are finely adapted for all ornamental plantations; the common green ſort alſo as a foreſt tree.

[2]ILEX *Caſſine.*

*Caſſinoide Ilex, commonly called Dahoon Holly, ſuppoſed allied to the Caſſine.*] Hath an upright branching ſtem, riſing fifteen or twenty feet high; oval lanceolate, ſerrated leaves, placed alternate; and ſmall white flowers, in ſhort thick cluſters from the ſides of the branches; ſucceeded by red berries, but rarely any in England. Is a native of Carolina.

Both theſe ſpecies of *Ilex*, together with all the varieties, are of the tree and ſhrub kind, and ever-green, being cloſely garniſhed with leaves all the year; and all the varieties of the *Ilex Aquifolium*, or common Holly, are extremely hardy, as well as very beautiful ever-greens, will proſper in any common ſoil and expoſure; but the Dahoon Holly is rather tender, being ſubject to injury from ſevere froſt, eſpecially when young; after, however, having occaſional ſhelter two or three years, of a frame, &c. in winter from hard froſt, and being gradually hardened, it will bear our ordinary winter very well, in a dry ſoil and ſheltered ſituation.

All the ſorts are fine furniture for every ornamental plantation: nothing can make a finer appearance than a collection of the ſeveral varieties of the firſt ſpecies, ſuffered to take their own natural growth; they being beautiful all the year, but appear rather with greater elegance in winter than ſummer; and the variegated kinds being interſperſed in the ſhrubbery, clumps, and other ornamental plantations, in aſſemblage with other hardy ever-greens, their beautiful variegations, with others of different hues, will greatly heighten the contraſt; and their numerous cluſters of red berries will add conſiderably to their luſtre in the autumn and winter ſeaſons. The Dahoon Holly is alſo a very fine plant, and worthy of admittance in every collection of ever-greens.

The firſt ſpecies was alſo in univerſal eſtimation for forming garden-hedges, both for ornament, and as fences, and makes the moſt beautiful hedge in the world. See HEDGES.

It was likewiſe greatly uſed to plant as detached or ſingle objects to train into regular figures, as globes, hemiſpheres, pyramids, &c.

And is likewiſe conſidered as a foreſt-tree, as its trunk will acquire a conſiderable bulk, where the trees are ſuffered to grow up, as in the places of their natural growth, in many of our foreſts and woods. The wood of it being very white and hard, is valuable for many purpoſes in the turnery and cabinet work; for as it takes a fine poliſh, is very proper for ſeveral kinds of houſhold furniture, inlayings, &c. hones for razors are made of this wood, and is fit for many other ſmall hard uſes.

Of the bark of this tree is made the compoſition called bird-lime. The bark being peeled

peeled about Midſummer, and put into a veſſel of ſpring-water, and boiled about twelve hours, when the white bark will ſeparate from the green; then lay the green bark on the floor of ſome cool cellar, covering it with any freſh rank weeds, and when lain a fortnight, pound it in a mortar till it becomes a tough paſte; this done, waſh it well in ſeveral waters till quite clean; put it then into an earthen veſſel, to ferment and purge four or five days, ſcumming off all filth that ariſes; then change it into a freſh veſſel for uſe; taking any quantity required, adding thereto a third part of well clarified gooſe or capon greaſe, mixing them well over a moderate fire, by conſtant ſtirring till cold, and the compoſition is prepared.

*Propagation, &c.*

The propagation of theſe trees is by ſeed, and by grafting and budding.

The common green Holly is raiſed plentifully from ſeed in the open ground; and all its varieties by grafting and budding upon ſtocks of that ſort, raiſed as above from the berries: for ſow the berries of any of the varieties, and they rarely produce any but plants of the common green kinds; ſo that there is no other certain method of continuing the variegated ſorts, in particular, than grafting or inoculating ſhoots, or buds of them into common Holly ſtocks. The hedge-hog-Holly berries, however, very commonly produce plants of the ſame ſort, with green leaves; but the variegated kinds thereof are continued by grafting or budding, &c. as obſerved for the other variegated kinds, &c.

By Seed.—The berries ripen in October and November, when a due quantity is to be gathered from any of the varieties; then obſerving, that as thoſe ſeeds generally lie two years before they germinate, they may either be buried in a heap in a hole or pit for a year, to be preparing for vegetation, then taken up and ſowed; or may be ſowed at once as ſoon as gathered, as hereafter directed, and they will come up the ſpring-twelvemonth following. But as theſe ſeeds, like the haws of the hawthorn, &c. never grow till the ſecond ſecond ſpring, as juſt obſerved, it is common to bury them a year; that is, in ſome dry part of the garden, dig a hole or trench a ſpade deep, or a little more, and one or two wide, or in proportion to the quantity of berries; which directly put into the hole or trench, and cover them over with ſome of the earth, five or ſix inches deep; or they may be buried in a large pot or tub, plunged over the top in the ground: in either method let them remain till next October; then having ground dug, and divided into four-feet-wide beds, with alleys between, trim with the rake or ſpade, an inch depth of earth evenly off the top of the bed; this done, take up the berries, and ſow them evenly on the bed, beat them down gently with the back of the ſpade, and cover them with the earth an inch deep, and lightly ſmooth the ſurface: or the berries may be ſowed in drills the above depth, making the drills ſix inches aſunder: the berries thus ſowed after being buried in the ground one year, will moſtly come up the ſpring following.

I, however, have obſerved, that the berries ſowed at once in the beds, as above, an inch deep, keeping the beds well weeded the following ſummer, that the berries all lying near the ſurface an equal depth, will all along enjoy an equal benefit of the air, ſun, and ſhowers, ſo as in the ſecond ſpring they generally riſe rather more regular and ſtrong than thoſe that were buried.

When the plants come up, keep them well hand-weeded, and if very dry weather, ſome water once a week will be of much ſervice.

Two years let them remain in the ſeed-bed, then in ſpring plant them out in nurſery-rows, two feet aſunder, and a foot diſtance in each row, there to remain until they are of proper ſize to be finally tranſplanted; and the proper ſeaſon for this is any time from the middle of September till that of March.

By Grafting and Budding.—All the varieties are, as above mentioned, continued by grafting or budding; and by either of which modes of propagation they may be multiplied at pleaſure, upon ſtocks of the common Holly, raiſed from ſeed, as above directed, which after being planted out in nurſery-rows, one or two years, they will be of proper ſize to graft or bud upon. The grafting is performed in March, by whip-grafting in the uſual way; and the budding to be performed in July or Auguſt, according alſo to the uſual method. See GRAFTING and INOCULATION.

The Dahoon Holly is alſo raiſed from ſeeds like the common kinds. The ſeeds are brought

brought annually from America, which, as ſoon as they arrive, ſhould be either buried in the ground like the common Holly for a year, or may be ſowed at once in pots of light ſandy earth, and plunged to their rims in dry earth about a twelvemonth: then, in ſpring following, if plunged in a hot-bed will greatly facilitate their growth, being careful to inure the plants to the full air; afterwards plunge the pots in a ſhady border till October, then remove them under a hot-bed frame for the winter; in ſpring thin them out, and plant them in ſeparate pots, to have occaſional ſhelter of a frame for two or three winters, then tranſplanted in ſpring into the full ground.

IMPATIENS, Touch-me-not, and Balſamine, or Balſam.

This genus furniſhes beautiful flowery annuals, of upright growth, branching a foot and a half, or two feet high; adorned with oval and ſpear-ſhaped leaves; and quinquepetalous irregular flowers.

Claſs and order, *Syngeneſia Monogamia.*

*Characters.*] CALIX, is two-leaved, coloured, and placed on the ſide of the corolla. COROLLA, is ringent, of five roundiſh unequal petals, and a one-leaved, hood-ſhaped nectarium at bottom, terminating at the baſe in a ſpur or tail. STAMINA, five ſhort incurved filaments, having the tops of the antheræ joined. PISTILLUM, an oval germen, no ſtyle, but a ſhort ſimple ſtigma. PERICARPIUM, an unilocular capſule, opening with elaſticity in five twiſted, ſpiral valves, and roundiſh ſeeds, fixed to the columnar receptacle.

This genus derives the name *Impatiens* from the elaſtic property of its ſeed-veſſel, which, when ripe, is ſo impatient of the touch, as to burſt open with elaſticity, and dart its ſeeds from their department with great velocity, eſpecially the firſt ſpecies. There are only two ſpecies of this genera uſually cultivated in the Engliſh gardens, both annuals; one is the *Noli me tangere*, or Touch-me-not, eſteemed more for the ſingularity of it's elaſtic capſules than beauty of its flowers: the other is that noted annual, Balſamine, or Balſam, comprehending, on ſeveral elegant varieties, producing numerous fine large flowers of ſingular beauty.

The ſpecies are;

[1]IMPATIENS, *Noli me tangere.*

*Noli me tangere, Touch-me-not, or Common Yellow Balſamine.*] Hath fibrey roots; an upright, jointed, ſucculent ſtalk, a foot and a half high; oval alternate leaves; and from the axillas of the ſtalks, long, ſlender, branching foot-ſtalks, each ſuſtaining many yellow flowers; ſucceeded by taper capſules, that burſts open, and dart out their ſeeds with elaſtic force.

It grows wild in England, but is cultivated in many gardens for curioſity.

[2]IMPATIENS *Balſamina.*

*Balſamina, or Balſamine, commonly called Balſam.*] Hath a fibrey root; an upright, thick, ſucculent ſtalk, branching all around, a foot and a half or two feet high; long, ſpear-ſhaped ſawed leaves, the upper ones alternate; and from the joints of the ſtalk and branches cluſters of ſhort foot-ſtalks, each ſuſtaining one large irregular flower, of different colours in the varieties; flowering from June or July till September.

*Varieties of this are.*] Balſamine with ſingle and double red flowers—ſingle and double white flowers—ſingle and double purple flowers—variegated ſingle and double flowers—large, double, variegated, ſcarlet and white flowers—large, double, variegated, purple and white flowers, &c. all of which are moſt beautiful annuals, but being originally of Indian growth, are ſomewhat tender, requiring moſtly to be raiſed and forwarded in hot-beds, &c.

Both the ſpecies and reſpective varieties are proper to be employed as plants of ornament to adorn the pleaſure-garden; but the ſecond ſort, *Balſamina*, and varieties, are conſiderably the moſt beautiful, excelling alſo moſt others of the annual tribe. The flowers of both the ſpecies are moderately large, and conſiſt each of five roundiſh unequal petals, and a monopetalous, hood-ſhaped nectarium, ending in a tail; the whole corolla is irregular, and ſomewhat reſembling the ringent, or grinning flowers (ſee COROLLA *Ringens*); and are ſucceeded by plenty of ſeed in autumn, by which all the ſorts are raiſed annually; the firſt ſort in the common ground in autumn or ſpring; and the ſecond chiefly in hot-beds in March and April. See their *Propagation*, &c.

The firſt ſpecies, *Impatiens noli me tangere*, being an indigenous plant of England, is very hardy; and is worth cultivation in gardens, both for the variety of its flowers, and the curioſity of its elaſtic ſeed-veſſels, &c. will grow freely in the open borders, by ſeed in autumn or ſpring, ſowed either where the plants are to remain, or for tranſplantation.

The

The *Impatiens Balſamina*, or Balſamine, is one of the fineſt annual flowers of our gardens; but being a native of India, is tender, not able to bear the open air here before May or June, and requires to be raiſed principally in a hot-bed in ſpring, under frames, &c. until June, as aforeſaid; remarking, however, that the ſeeds will alſo grow in the natural ground in May, rarely before, and more freely then, if covered with a hand-glaſs, &c. but the plants ſo raiſed will not begin to flower ſo ſoon by five or ſix weeks, as thoſe forwarded by artificial heat, under frames and glaſſes. All the varieties are of ſomewhat luxuriant growth, they frequently having ſtems thicker than good walking-canes, branching out into large heads, and every branch productive of abundance of flowers; and as the branches advance in length, furniſh a ſucceſſion of bloom for two or three months; obſerving that the variegated doubles have the greateſt merit, which are ſometimes as large as middling roſes, and the petals multiplied in many ſeries; and all the varieties produce ſeed plentifully in autumn.

The fine varieties of this elegant ſpecies, are commonly planted in pots to decorate fore-courts, and other conſpicuous departments; and the more inferior varieties are generally diſpoſed in the common borders, as all the varieties, after being raiſed as above hinted, until June, will grow freely in the open ground, the remainder of the ſummer.

*Propagation and Culture, &c.*

The propagation of both the ſpecies, and varieties in general, is by ſeed; remarking, that the plants being but of one ſummer's duration, the ſowings muſt be performed annually.

The *Noli me tangere* may be ſowed in autumn, i. e. September, October, or November, or early in ſpring, February or March, in any bed or border, either in patches where the plants are to remain, or for tranſplantation, half an inch deep; and when the plants are come up an inch or two high, thin them to three in each patch; obſerving the ſame if they are to be tranſplanted. From the ſcattered or ſelf-ſown ſeeds of this ſpecies in autumn, many young plants will riſe naturally the following ſpring.

The *Balſamine* is always ſowed in the ſpring, in March or April, and ſhould be performed principally in a hot-bed, as before obſerved; and the plants continued therein till June, and if under deep frames may be drawn up two or three feet high by the latter end of that month.

Particular attention is requiſite to procure ſeeds of the fine variegated doubles, eſpecially if intended to exhibit a grand ſhew of them in pots, or principal borders and flower-beds. Sow the ſeed either in pots of light rich earth, half an inch deep, plunging the pots in a hot-bed; or it may be ſowed immediately in the earth of the bed in ſmall drills the above depth: the plants will ſoon appear, which are to be managed as other annuals of ſimilar temperature, with reſpect to giving air daily, and frequent moderate waterings. When they are two or three inches high, it it is proper to prick them out, either in the ſame, or in a freſh hot-bed, under a proper frame; raiſing them up with the roots entire, and either plant ſome of the beſt in pots (thirty-twos), one plant in each, up to their ſeed leaves, and plunge the pots in the hot-bed, as obſerved for the ſeed, or plant them into the earth of the bed, four or five inches aſunder: in either method give a moderate watering directly, and occaſional ſhade from the mid-day ſun till they are freſh rooted; repeating the watering frequently. After having grown here about a month, they will be ſo much advanced in growth as to interfere with each other, when thoſe in pots may be turned out with the earth about their roots into larger pots (twenty-fours), to remain; which if plunged alſo in the hot-bed will greatly forward the plants. Thoſe planted in the earth of the hot-bed, if any of them are deſigned for pots, ſhould alſo be then taken up with balls and potted, and treated as above, giving water and occaſional ſhade as before. As they all advance in growth, raiſe the frame, if neceſſary, that they may grow to their full height; for it is a principal property to have theſe plants of ſome conſiderable ſtature. See ANNUAL PLANTS.

They muſt remain conſtantly in the frame till June, then harden them gradually to the full air, ſo as they may be removed into it fully towards the middle or latter end of that month, according to their ſize, and temperature of the ſeaſon; at which time alſo thoſe deſigned for the borders ſhould be tranſplanted therein with balls of earth about their roots, giving water at planting, repeating it daily, or as there ſhall ſeem occaſion, till they have taken good root.

As ſoon as they are removed into the open air, both thoſe in pots and in the full ground ſhould have a tall ſtick placed to each for ſupport, to which tie their ſtems neatly.

Let thoſe in pots be often watered in dry weather; once or twice a day in very hot weather will be neceſſary.

All the varieties of Balſamine may be raiſed to a great perfection in a ſtove, with little trouble, at almoſt any time of the year; ſowing the ſeeds in pots, and plunge them in the bark-bed, and when the plants are two inches high, plant them in ſeparate pots, which plunge alſo into the bark-bed, to remain until the plants are grown up.

But in default of hot-beds, &c. theſe plants may alſo be raiſed in the common ground for an autumnal bloom: the ſeeds will not, however, ſucceed in the natural earth before May, and even then muſt be ſowed in a warm dry border, or in pots placed in a warm ſituation, and if covered with hand glaſſes occaſionally will be an advantage, though they will often come up without any ſhelter at all, and flower abundantly in Auguſt and September; ſometimes too, ſeeds having ſcattered or ſowed themſelves the year before in the borders, will remain ſound, and come up the following year in May or June without art, and flower all autumn, until killed by the cold.

I would, however, obſerve, that plants raiſed and forwarded in a hot-bed, arrive not only much ſooner to perfection, ſo as to have the pleaſure of their bloom ſix weeks ſooner; but by being thus forwarded into bloom betimes in ſummer, they always produce the beſt ſeeds.

To ſave ſeeds of the fine variegated doubles, ſome pots of them ſhould be placed when in full bloom, either in an airy glaſs-caſe, having the windows in front to open, or in ſome deep frame to be ſheltered with the glaſſes occaſionally from great autumnal rains, and cold nights; you will thereby have a much greater chance of having plenty of ſeed perfectly ripened.

INARCHING. See GRAFTING.

INFLORESCENTIA, *Inflorescence*, or manner of flowering of all kinds of plants.

The term Inflorescence, ſignifies the mode or manner in which flowers are produced upon the plants, which is various, though in all the known plants and trees in the world, there is but ſeven or eight different modes of flowering, which are expreſſed by the following terms.

*Capitulum*, *Corymbus*, *Panicula*, *Racemus*, *Spica*, *Thyrſus*, *Verticillus*, and *Umbella*; for an explanation of each of which, ſee each under its proper head.

INOCULATION, or budding, a method of propagation, practiſed occaſionally for various trees, but more particularly the fruit-tree kind.

The work of Inoculation, or budding, is the inſerting an eye or bud of one tree into the ſide of another, and the bud uniting therewith, ſhoots out into branches, becomes a tree, producing flowers and fruit the ſame in all reſpects as thoſe of the tree from whence it was taken; thus any ſort of tree may be multiplied at pleaſure, ſince every bud will form a tree exactly of the ſame ſort, though upon a different ſtock and root; as for example, inſert buds of peach, nectarine, and apricot trees into plum-ſtocks, which being headed the ſpring after, the bud ſhoots and becomes the tree; which, though the root, and the bottom of the ſtem is a plum-tree, the upper branchy part being produced from the inſerted bud, is a peach or nectarine, &c. and produces fruit exactly the ſame as that from which you took the buds. It is, therefore, as obſerved of grafting, &c. the only method by which we can with certainty continue and multiply the different approved varieties of many kinds of fruit and other trees; for although their ſeeds will readily grow and become trees, yet, as we formerly obſerved, ſow the ſeed, or kernels of the fineſt varieties of fruit, not one tree out of a hundred, ſo raiſed, will produce any like the original, and but very few that are good, ſo variable are ſeedling fruit-trees, and many others; but the trees or ſtocks, ſo raiſed, being budded with the proper approved ſorts, the buds produce invariably the ſame kind of tree, fruit, flowers, &c. continuing unalterably the ſame.

The work of budding is performed in ſummer, principally in July and Auguſt; by inſerting buds into the ſides of the ſtocks, leaving their heads entire, and the buds remaining dormant till next ſpring, when the ſtock being headed, they ſhoot forth with vigour.

This mode of propagation is particularly uſed for peaches, nectarines, and apricots, which ſucceed better by budding than graſting, and are uſually worked upon plum-ſtocks raiſed from ſeed, and ſometimes by ſuckers, layers, and cuttings, upon particular occaſions,

ſions, as noticed in their reſpective articles. Peach, nectarines, and apricots are alſo often budded upon their own ſtocks, i. e. ſtocks raiſed from the kernels of theſe kinds of fruit; they, however, are commonly more ſtrong and durable upon plum ſtocks.

Plums and cherries are alſo very often propagated by Inoculation as well as by grafting; the cherry, however, is generally the moſt proſperous by the latter method, as being more apt to gum and go off by budding. Both theſe ſorts being of the ſame genus, will grow upon ſtocks of each other, but much the beſt upon their own ſtocks, that is, plum upon plum, and cherry upon cherry ſtocks.

Apples and pears may likewiſe be propagated by Inoculation as well as by grafting, though as they grow freely by grafting, which being the moſt eaſy and expeditious, they are commonly propagated by that method.

In ſhort moſt kinds of fruit-trees, and others that are propagated by grafting, will alſo ſucceed by Inoculation; grafting, however, is more particularly adopted for ſome ſorts, and budding for others, as is always explained under their reſpective articles.

Many ſorts of foreſt-trees, and flowering-trees, &c. both deciduous and ever-greens, may alſo be propagated by Inoculation, and is a certain method of propagation, to continue particular varieties, ſuch as many of the variegated-leaved kinds, as the variegated hollies, &c. and many other ſorts, which is always mentioned in their propagation and culture, under the proper genera.

The Inoculation for all ſorts is commonly performed upon young trees, raiſed from ſeed, ſuckers, layers, &c. which, when raiſed purpoſely for budding and grafting upon, are called ſtocks, and which, when about half an inch thick in the bottom of the ſtem, or a little more or leſs, are of proper ſize for budding; though it may be performed upon ſtocks from the ſize of a gooſe-quill, to an inch or more big: remarking that all Inoculation muſt be performed principally upon ſtocks or trees of the ſame genus, for it is but few trees that will ſucceed upon ſtocks of a different genera. Peaches, however, and nectarines, being of the genus *Amygdalus*, grow freely upon the *prunus*, or plum-tree, as being very near related, and is the moſt common ſtock on which theſe ſorts are uſually budded. But in moſt other kinds of fruit-trees, and others, the ſtocks of the ſame genus or fraternity, muſt be ſtrictly adhered to, both for budding and grafting. See GENUS.

For inſtance, peaches, nectarines, and almonds, may be inoculated either upon their own, or plum-ſtocks, but principally upon the latter to have durable trees. Apricots being of the genus *Prunus*, muſt be budded chiefly on plum-ſtocks, or elſe upon their own. Cherries upon cherry-ſtocks; apples upon apples; pears upon pears, or upon quince-ſtocks, to have dwarfs. Obſerving alſo the ſame of all other kinds of trees and ſhrubs, that are propagated by Inoculating and grafting.

The ſtocks are very commonly raiſed from ſeed, i. e. the kernels or ſtones of the above ſorts of fruit, &c. ſowed in autumn or ſpring, in beds in the nurſery, an inch or two deep; they will come up in April or May following, which when a year or two old, tranſplant them in nurſery-rows, two feet aſunder, and fifteen or eighteen inches diſtant in the rows; here to ſtand for budding, keeping them to one ſtem, and ſuffer their top to run up entire; and having two or three years growth, when about the ſize of your little finger at bottom, or a little more or leſs, they are of due ſize for budding; ſtocks are alſo often raiſed from ſuckers ariſing from the roots of the trees of the reſpective ſorts; likewiſe by layers and cuttings. See STOCKS.

Note, Budding may alſo be performed occaſionally upon trees that already bear fruit, when intended to change the ſorts, or have different ſorts on the ſame tree, or to renew any particular branches of a tree, performing the operation in the young ſhoots of the year, or of one or two years growth.

*Of performing the Operation.*

The Inoculation is always performed in ſummer, when the rind of the ſtock, and that of the cuttings for the buds, will readily ſeparate from the wood; for the buds being cut off from the ſhoots an inch or more long, the woody part adhering thereto is ſtripped off, are then inſerted into the ſide of the ſtock, between the rind and wood thereof, the head remaining entire at preſent; and is done by ſlitting the bark of the ſtock croſs ways, and perpendicularly, as directed below; and the rind and wood being then divided, the bud is inſerted between them; which remaining dormant till ſpring following, when the ſtocks are headed down to the place of inſertion, the bud ſhoots forth, and forms the

new tree, which in ſome ſorts will bear fruit in two or three years.

The proper ſeaſon for performing the operation of budding is from about the middle of July until the middle or latter end of Auguſt: ſome however begin to bud in June, but the buds inſerted ſo early, are apt many of them to ſhoot the ſame year, and the ſhoots not having time to harden, are very liable to be killed in winter; determine therefore upon the end of July, or firſt fortnight in Auguſt to perform the operation, and your buds will all remain dormant till ſpring when they will ſhoot with vigour.

The buds are to be taken only from the young ſhoots of the year, i. e. ſhoots of the ſame ſummer's growth, which muſt be cut from the trees of the ſorts you intend to propagate. Chuſe them from healthful thriving trees; and if fruit-trees, from ſuch that bear the fineſt fruit of their reſpective kinds and varieties: from which cut a quantity of the beſt moderately ſtrong young ſhoots, each day as they are wanted, and as they are gathered cut off all the leaves, not quite cloſe, reſerving about a quarter of an inch of their foot-ſtalks, trimming off alſo the ſoft unripened top-end of each cutting, then cover them from the ſun and air, and take them out as you want them; obſerving as each cutting furniſh many buds, they are to be cut off about an inch and a half long, one at a time, as they are inſerted in the ſtock; remarking that thoſe in the middle-part of the cutting are preferable to thoſe towards each end, though in caſes of ſcarcity of cuttings, every one of them may be uſed; one bud only is commonly inſerted in each ſtock; ſome, however, place two, one on each ſide oppoſite.

The proper height to bud the ſtocks is various, and may be within from about three or four inches of the ground, to ſix feet or more; that is, to have dwarf-trees, they muſt be budded from within about three to ſix inches of the bottom, that they may firſt furniſh branches near the ground. If for half-ſtandards, bud at the height of three or four feet; and if for full ſtandards, at from about five to ſix or ſeven feet height; ſo that you muſt train your ſtocks accordingly, ſome for dwarfs, ſome for half ſtandards, and others for full ſtandards, as is more fully particularized under the ſeveral articles. I would remark, however, that for half and full ſtandards, the budding may, if you pleaſe, be performed as low in the ſtock as for dwarfs, and the firſt ſhoot from the bud trained up to a proper height for a ſtem.

The proper implements and materials for budding, is a ſmall budding-knife, having a flat thin haft, to open the bark of the ſtock, to admit the buds, and a quantity of new baſs ſtrings to tie them.

To proceed to the operation.—Obſerve in the operation of budding, the head of the ſtock is not to be cut off, as in graſting, but the bud is inſerted into the ſide, and the head to remain entire till ſpring after, and then cut down; therefore fix on a ſmooth part on the ſide of the ſtock, at the proper height, rather on the northward ſide, away from the ſun, and with your budding-knife make a horizontal cut acroſs the rind of the ſtock, quite through to the firm wood, then, from the middle of this tranſverſe cut, make a ſlit downward perpendicularly an inch or more long, going alſo quite through to the wood. This done, proceed with all expedition to take off the bud, holding the cutting in one hand with the thickeſt end outward, and with the knife in the other hand, enter it about half an inch, or more, below a bud, cutting near half way into the wood of the ſhoot, continuing it with one clean ſlanting cut, about half an inch or more above the bud, ſo deep as to take off part of the wood along with it, the whole about an inch and a half long; then directly with the thumb and finger, or point of the knife, ſlip off the woody part remaining to the bud; which done, obſerve whether the eye or gem of the bud remains perfect; if not, and a little hole appears in that part, it is improper, and another muſt be prepared; this done, placing the back part of the bud between your lips, expeditiouſly with the back of the knife, or rather the flat haft thereof, ſeparate the bark of the ſtock on each ſide of the perpendicular cut, clear to the wood for the admiſſion of the bud, which directly ſlip down cloſe between the wood and bark to the bottom of the ſlit; and then cutting off, if neceſſary, the top-part of the bud even with the horizontal cut, to let it completely into its proper ſocket; let the parts then be immediately bound round with a ligature of freſh baſs, previouſly ſoaked in water to render it pliable and tough, beginning a little below the bottom of the perpendicular ſlit, proceeding upward cloſely round every part, except juſt over the eye of the bud, and continue it a little above the horizontal cut, not too ſtrait, but juſt ſufficient

cient to keep the whole close, exclude the air, sun, and wet, and promote the junction of the stock and bud. In this manner proceed with the Inoculation of every stock till the whole is finished. The junction of the stocks and buds will be effected in three weeks; and next spring, the head of the stock being cut off, the buds will push out, each producing one shoot, sometimes a yard or more long by the end of summer.

This operation of budding may to those unacquainted, appear a tedious work; but an expert hand will bud several hundred in a day.

In a fortnight at farthest after budding, you will be able to judge which buds have taken, by their fresh appearance.

Three weeks, or thereabouts, after the operation, all those buds that have succeeded, will be firmly united with the stock, and the parts be swelled, and require the bandage to be loosened: let, therefore, the tyings be then taken wholly away, that the buds may have full liberty of growth, in common with the other parts of the stock; which is all that is necessary to be further done until spring, when the stocks must be headed down to the bud.

In spring, about February or March, just before the trees begin to shoot, cut off the head of the stock sloping, exactly above the bud, not three or four inches higher as is commonly done; after this, the whole effort of the stocks being directed to the buds, they will soon push forth strong, one shoot from each bud; many shoots will also arise from the stock, but these must be constantly rubbed off as often as they appear, that all the powers of the stock be collected for the vigour of the bud-shoot, which now commences the tree, and by the end of summer will, in some sorts, be advanced three or four feet high; and in the autumn or spring following, the young trees may be transplanted into the places where they are to remain, or may remain longer in the nursery as shall be convenient, according to the purposes for which they are designed.

Observe, however, that whersoever the trees are, if designed to be dwarfs, the first shoot from the bud, should in the spring after it is produced, be shortened or headed down to four or five eyes, to force out first some lower shoots near the bottom, as directed for dwarf-trees, espaliers, &c. but if designed for half or full standards, and if they were budded at proper height at first in tall stocks, and designed for detached standards in the open ground, the first shoot of the bud may either be shortened as above, to four or five eyes, to provide lateral branches near the top of the stem, to form a spreading head; or may be suffered to grow up in height, and branch out in its natural way, whereby it will form a more erect head of loftier growth; remarking, however, that such full or half standards as are designed for walls, and were budded high on the stocks, must necessarily have the first shoots headed down in the spring following, to force out lateral shoots to furnish the allotted space of walling; observing again on the other hand, that trees designed for any sort of standards, and are budded low in the stock, the first shoot of the bud must be trained up for a stem to a proper height before it is stopped; and when arrived to its proper stature, should be topped to throw out shoots to form a head at the desired height, either for walls or open-ground standards. See DWARF-TREES, ESPALIERS, WALL-TREES, and STANDARD-TREES, &c.

For the further management of budded trees, see the different articles under their proper genera, where the general culture of each sort, both dwarfs and standards, is fully exhibited.

IPOMOEA, *Quamoclit, or Scarlet Convolvulus.*

The plants are herbaceous, twining climbers, natives of the Indies, consisting of tender annuals and perennials of the flowery kind, rising with twining stalks upon support six or eight feet high, adorned with simple, cordated leaves, and monopetalous flowers.

Class and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is small, five-parted, and permanent. COROLLA, is monopetalous and funnel-shaped, the tube very long and nearly cylindric, and the limb five-parted and spreading at top. STAMINA, five long filaments, and roundish antheræ. PISTILLUM, a roundish long style, and headed stigma. PERICARPIUM, a roundish trilocular capsule and three seeds.

There are several species, but not more than one common to the English gardens, which is a climbing flowery annual, very nearly allied to the *Convolvulus.*

IPOMOEA *Coccinea.*

*Scarlet Ipomoea, commonly called Scarlet Convolvulus.*] Ipomoea, with long, slender, twining stalks, rising upon support six or seven

ven feet high; heart-formed, pointed leaves, angulated at the baſe; and from the ſides of the ſtalks and branches, many ſlender foot-ſtalks, each ſupporting ſeveral large funnel-ſhaped, beautiful ſcarlet flowers.

*Variety* ] With orange-coloured flowers.

Both the varieties are annual, riſe from ſeed in ſpring, flower in July and Auguſt, &c. ripen ſeeds in September and October, and wholly periſh ſoon after.

They are tender, require to be raiſed and forwarded in a hot-bed until the middle or latter end of May, or beginning of June, according to the temperature of the ſeaſon; and then may be planted out to adorn the borders, and ſome may be planted in pots to move occaſionally to ornament any particular place; in either method, you muſt have ſticks placed for them to twine upon.

The propagation is by ſeed annually, in March or April, in a hot-bed, along with other annuals of ſimilar quality; may be ſowed in ſmall drills, half an inch deep; and in May or June, as aforeſaid, plant them out into the open ground; or, if when the plants are come up an inch or two high, they are taken up and pricked down upon the ſame, or rather in a new hot-bed, it will forward and prepare them better for final tranſplantation: or the ſeed may be ſowed in ſmall pots, three or four ſeeds in each, and the plants may be turned out with the earth about their roots, where they are deſigned to flower: obſerving during their reſidence in the hot-bed, to admit air, and give refreſhment of water, as directed for annuals of the ſame temperature. See ANNUAL PLANTS.

IRIS, *Flower-de-luce*, or Flag-flower, &c.

This genus is very comprehenſive in a numerous family of herbaceous, flowering perennials, both of the fibrous, tuberous, and bulbous-rooted kind, producing thick annual ſtalks, from three or four inches to a yard high, terminated by large hexapetalous flowers, having three of the petals reflexed quite back, and three erect, moſt of which are very ornamental garden flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, a permanent ſpatha. COROLLA, ſix oblong obtuſe petals, the three outer are reflexed back, the interior ones erect, and all of them united at the baſe. STAMINA, three ſubulate filaments lying on the reflexed petals, and oblong depreſſed antheræ. PISTILLUM, an oblong germen under the corolla, ſhort ſtyle, and large ſtigma divided into three broad ſegments. PERICARPIUM, an oblong, angular, trilocular capſule, and many large ſeeds.

To this genus is now added, the *Hermodactylus*, or Snake's head Iris—*Xiphium*, or Bulbous Iris—and a ſpecies of *Siſyrinchium*; their generic characters determining them to be all ſpecies of this genus. Each of theſe, however, is exhibited under a ſeparate head.

The flowers of all the ſpecies of this genus have great ſingularity in their ſtructure; they are large, conſiſting each of ſix petals, the three interior ones ſtanding erect, called ſtandards, and the outer ones reflexed backward, called falls, which in ſome ſpecies are bearded, having a downy matter running along the middle; other ſpecies are unbearded, having the bent petals ſmooth, and in the centre a ſort of three-lobed nectarium, like three ſmaller petals, one generally inclining towards each fall.

So that they may be divided into two claſſes, the bearded, and unbearded kinds.

### *Bearded Kinds.*

Theſe are moſtly of the ſword-leaved kind; have thick, knotty, fleſhy, perennial roots; ſending up annually cluſters of long, flat, enſiforme, erect leaves, from three inches to two feet in length; and amidſt them upright thick flower-ſtalks, of various ſtatures in different ſorts; ornamented in moſt ſpecies with leaves the ſame as the radical ones; and terminated by the flowers, in ſome but one, others two, three, or more, one above another, appearing moſtly in May, June, and July; ſucceeded in ſeveral of them by plenty of ſeed.

¹IRIS *Pumila.*

*Dwarf Auſtrian Iris.*] Hath a large, fleſhy, knotty root, riſing above-ground; crowned with many broadiſh erect leaves, three or four inches long; and ſhort erect flower-ſtalks, three inches high; each terminated by one large bearded flower, of different colours in the varieties; flowering in May.

*Varieties are.*] Dwarf Iris, with pale-purple flowers—deep-purple flowers——blueiſh flowers—with red flowers——bluſh-coloured ſweet-ſcented flowers—white flowers——and with variegated flowers.

All theſe varieties are very pretty garden flowers, for the fronts of borders, &c.

²IRIS *Suſiana.*

*Chalcedonian Black and White Iris.*] Hath a thick, fleſhy, ſpreading root; crowned by ſeveral long, narrow, ſharp-edged, erect leaves,

leaves, embracing one another at the baſe; and upright, jointed, firm ſtalks, two feet high; each terminated by one very large bearded flower, having the three up-right petals, or ſtandards, very broad, and variegated with black and white ſtripes and duſky ſpots, and the three falls or bending petals almoſt black, and conſtructed like an open mouth, the ſtamina repreſenting the tongues; ſo that the whole flower exhibits a ſtrange and formidable appearance.

[3]IRIS *Germanica.*

*German Violet-coloured Iris.*] Hath a thick, jointed, fleſhy, ſpreading root; cluſters of ſharp-edged, pointed leaves, a foot and a half long, embracing each other below, but ſpread out fan-faſhion above; and upright, branchy flower-ſtalks, two feet high; ſuſtaining many bearded violet-coloured flowers, one above another, the lower ones having foot-ſtalks; flowering in the end of June and July, ſucceeded by plenty of ſeeds.

[4]IRIS *Florentina.*

*Florentine White Iris.*] Hath a thick, fleſhy, ſpreading root; cluſter of broadiſh ſharp-edged leaves, a foot and a half long; and upright flower-ſtalks, taller than the leaves; terminated by two or three cloſe-ſitting white flowers; appearing in June and July.

[5]IRIS *Squalens.*

*Squalid Purple and Yellow Iris.*] Hath thick fleſhy roots; broad, rough, ſharp-edged leaves, a foot and a half long; and upright flower-ſtalks, near two feet high; ſuſtaining ſeveral bearded, ill-coloured, purple and yellow flowers; appearing in June and July.

[6]IRIS *Sambucina.*

*Sambuca-ſcented Violet and Blue Iris.*] Hath thick roots; broad, ſharp-edged, pointed leaves, a foot and a half long; and upright flower-ſtalks, about two feet high; terminated by ſeveral bearded, violet and blue flowers, having the falling petals plane, and the erect ones emarginated; and ſmell ſtrongly like elder; appearing in June or July.

[7]IRIS *Variegata.*

*Variegated Hungarian Iris.*] Hath thick knotty roots; crowned by many broad, ſharp-edged, pointed leaves, near two feet long; and upright ſtalks, two feet high, branching near the top; each diviſion ſupporting two or three large bearded flowers, having the erect petals yellow, the falls white, ſtriped with purple, and variegated ſtigmas; flowering in June.

[8]IRIS *Aphyllis.*

*Leafleſs, or Naked-ſtalked, purple and White Iris.*] Hath thick roots; very broad leaves, a foot or two long; and upright leafleſs ſtalks, the length of the leaves; terminated by three or four large, bearded, bright purple flowers, having the falls ſtriped with white; appearing in May.

[9]IRIS *Biflora.*

*Twice-flowering Portugal purple Iris.*] Hath a thick, knotty root; broad ſhort leaves, eight or ten inches long; and upright ſtalks, ſix or eight inches high, branching at top into foot-ſtalks; each ſupporting two or three bearded, deep-purple flowers; appearing in May, and ſometimes again in autumn.

*With Unbearded Flowers.*

Moſt of theſe are alſo of the ſword-leaved kind, and moſtly with thick fleſhy roots, all perennial, with the leaves riſing in cluſters from the root annually, and amidſt them the flower-ſtalks, ſupporting the flower at top.

[10]IRIS *Verna.*

*Spring-flowering Dwarf Virginia Iris.*] Hath a fibrous root; crowned by a cluſter of very narrow graſs-like leaves, eight or nine inches long; and upright flower-ſtalks, ſhorter than the leaves; terminated by one unbearded, ſweet-ſcented flower, having blue ſtandards, and purple falls; flowering early in May.

[11]IRIS *Verſicolor.*

*Variable-coloured American Iris.*] Hath a thick fibry root; ſword-ſhaped leaves, a foot long; upright taper ſtalks, a little taller than the leaves; terminated by two or three unbearded flowers above one another, having light-blue ſtandards, and deep purple falls, variegated with a broad white line through the middle; flowering in June.

[12]IRIS *Graminea.*

*Graſs-leaved Auſtrian Iris.*] Hath fibrey roots, narrow, flat, graſſy leaves, about a foot long; upright, two-edged ſtalks, ſhorter than the leaves; terminated by two or three ſmalliſh unbearded flowers above each other, having reddiſh purple ſtandards variegated with violet, and light purple falls, with a broad yellow ſtripe along the middle, adorned with purpliſh ſtreaks; and a ſexangular germen; in July.

[13]IRIS *Spuria.*

*Stinking narrow-leaved Meadow Iris.*] Hath a thick fibrey root; crowned with many very narrow leaves, near a foot long; and upright

taper

taper ſtalks, a little taller than the leaves; adorned with three or four unbearded flowers, having pale blue ſtandards, and purple variegated falls, with a white line down the middle; and a ſexangular germen; flowering in July. Is a native of Germany.

[14]IRIS *Martinicenſis.*

*Martinican Blackiſh yellow Iris.*] Hath long narrow leaves, upright ſtalks, ſupporting two or three unbearded blackiſh-yellow flowers, glandulous near the baſe, and a trigonous germen; flowering in June or July.

[15]IRIS *Sibirica.*

*Siberian Narrow-leaved blue Iris.*] Hath thick fibrey roots; crowned with narrow ſword-ſhaped leaves, a foot and a half long; upright foot-ſtalks taller than the leaves; terminated by two or three unbearded flowers above each other, having light blue ſtandards, and deep blue falls ſtriped with white; flowering in July, and ripen plenty of ſeeds.

[16]IRIS *Fœtidiſſima.*

*Moſt Stinking Iris, commonly called Stinking Gladwin.*] Hath thick fibrous roots; ſword-ſhaped graſs-green leaves, fifteen or eighteen inches high; and upright one-angled flower-ſtalks, about the height of the leaves; ſuſtaining two ſmalliſh unbearded purple flowers, having the interior petals ſpreading; flowering in July.

*Variety.*] With ſtriped leaves.

Both the varieties retain their leaves all the year, and the ſtriped-leaved ſort forms a pretty variety at all ſeaſons; they grow wild in marſhy places in England, but are admitted into gardens for variety.

[17]IRIS *Pſeudacorus.*

*Baſtard-acorus, or common yellow Flag-flower of our marſhes.*] Hath a thick, fleſhy, ſpreading root; crowned with many long, ſword-ſhaped, erect leaves, two or three feet in length; and upright firm flower-ſtalks, a yard high, terminated by a few yellow flowers, having the interior petals leſs than the ſtigma; flowers in June. It grows wild in marſhy places, and ſtanding waters all over the kingdom, and is only cultivated ſometimes for variety.

All the above ſeventeen ſpecies are very hardy perennials, of great duration in root, but in moſt are annual in leaf, and all of them renew their flower-ſtalks annually in ſpring, and decays in autumn ſoon after they have flowered and produced ſeeds. They are all proper ornamental furniture for the compartments of the pleaſure-gardens, either in borders or to intermix in the ſhrubbery-clumps, between the ſhrubs and trees, for they will proſper in any common ſoil and ſituation, and effect a very agreeable variety during their bloom; which in the different ſorts is continued two or three months, i. e. May, June, and July.

They may be planted at almoſt any time from September till March, though September, October, and November is the moſt eligible ſeaſon, as they will be more firmly rooted, ſo as to flower ſtrong the following ſummer; obſerving, that as moſt of the ſorts are apt to ſpread greatly at root, they ſhould be reduced occaſionally, either by ſlipping them, or tranſplanting every two or three years, or as you ſhall ſee neceſſary to preſerve them within due compaſs.

The propagation of all the ſorts is effected abundantly by dividing their roots, as they multiply exceedingly by off-ſets, which may be parted any time from September until March. I would, however, adviſe it to be done principally in autumn, in September, October, or November, whereby they will be more firmly rooted, and flower in good perfection the following ſummer.

They are alſo eaſily raiſed from ſeed, which is the method to obtain new varieties: ſow the ſeed in autumn, ſoon after it is ripe, any time in September, in a bed or border of common earth, and rake it in, and the plants will riſe in ſpring following: which in autumn ſhould be tranſplanted, and they will flower a year or two after.

*Hermodactyle Iris.*

This was formerly a diſtinct genus, but its generic *Characters* prove it only a ſpecies of *Iris.*

[18]IRIS *Tuberoſa (Hermodactylus).*

*Tuberous-rooted Iris, or the Hermodactyle, or Snake's-head Iris.*] Hath a large tuberous root, conſiſting of large tubers; ſending up ſeveral long tetragonous, or four-cornered leaves; and amidſt them an upright ſtalk, a foot or more high, terminated by one large purple unbearded flower, in April or May; but rarely produce ſeed in England.

It is a native of Arabia, but is very hardy, and long an inhabitant of our gardens; is eaſily propagated by its tubers, which the main roots furniſh by off-ſets annually, and ſhould be taken off at the decay of the leaves in ſummer.

This

This ſpecies is remarkable for ſtriking its roots deep into the ground, often ſo low as to loſe themſelves, eſpecially in very light ſoils, in which caſe they ſhould be annually tranſplanted, when their leaves decay.

*Xiphium, or Bulbous Iris.*

The *Xiphium*, including the bulbous and Perſian Iriſes, was formerly conſidered as a diſtinct genera; but, according to the Linnæan ſyſtem, all the ſorts are now retained as ſpecies and varieties of this genus, their characters agreeing exactly with the common *Iris*; the flowers conſiſting of ſix petals, three of them ſtanding erect, and three reflexed backward, &c.

There are but two ſpecies, the common Bulbous Iris, and Perſian Bulbous Iris; both very hardy, and the former of which is prolific in many fine varieties; the latter is alſo a a beautiful ſpring flower.

[19]IRIS *Xiphium.*

*Xiphium, or Bulbous Iris.*] Hath a large roundiſh, fleſhy, bulbous root; ſending up ſeveral awl-ſhaped, channelled, ſharp-pointed leaves; amid them an upright ſhorter flower-ſtalk, from half a foot to a foot or more high; terminated by two or three large beautiful flowers of different colours in the varieties.

*Varieties of this are.*] Common blue flowered bulbous Iris—with violet-coloured flowers—white flowers—purple-flowered—yellow flowering—with blue ſtandard petals and white falls—with blue ſtandards and yellow falls—with ſtriped flowers—broad-leaved with blue flowers—broad-leaved purple-flowered—ſweet-ſcented blue-flowered—ſweet-ſcented purple flowers—and with variegated ſweet-ſcented flowers: with many other intermediate varieties.

All theſe ſorts flower beautifully in May and June, in the open borders, &c. though ſome a month or ſix weeks earlier than others, and are ſucceeded by plenty of ſeeds in autumn; and may be propagated plentifully by off-ſets of the root, like other bulbs.

[20]IRIS *Perſica.*

*Perſian Bulbous Iris.*] Hath a large oval bulbous root; ſending up ſeveral awl-ſhaped channelled leaves, ſix inches long; and amid them an upright ſhort ſtalk, three inches high, crowned by one or two large elegant flowers, with the interior petals ſpreading and ſerrated, having whitiſh-blue ſtandards, and pearly white falls, variegated with yellow and purple, and of a fragrant ſcent; appearing in February and March. It is valuable both for its early bloom and the great beauty of its flowers.

Both the above ſpecies and reſpective varieties of bulbous Iris, have great merit as flowery plants; will grow freely in any of the common borders, and are pretty ornaments for the pleaſure-garden; planting them, in autumn, to adorn the principal borders, in ſmall patches towards the front, ſetting them about three inches deep; they will all flower the following year at their proper ſeaſon; and the bulbs will abide for years, and flower annually; it is, however, proper to take them up every ſecond or third year at leaſt, at the decay of the leaves, to ſeparate the off-ſets, &c.

The propagation of both theſe ſpecies of bulbous Iris, and varieties, is principally by the off-ſets of the roots, like other bulbs, which they afford in tolerable plenty, eſpecially if ſuffered to remain undiſturbed two or three years, when they will be greatly encreaſed; the proper time for lifting the roots and ſeparating the off-ſets, is in ſummer, when the leaves decay, managing them as other bulbs. See BULBUS.

They are alſo propagated by ſeed to gain new varieties. Sow it in September, in a bed of light ſandy earth, that has only the morning ſun, covering it with fine earth half an inch deep; or it may be ſowed in pots, boxes, or tubs of the like light ſoil, which may be moved at pleaſure to a warm, or ſhady ſituation at different ſeaſons: the plants will riſe in ſpring following, which in the ſummer twelvemonth after, at the decay of the leaves, remove from the ſeed-bed, and plant them into another, three inches apart, and two deep, to remain two or three years, when they will flower ſufficiently ſtrong to diſcover their properties; then are to be managed as the other large bulbs.

*Siſyrinchium Iris.*

[21]IRIS *Siſyrinchium (Bulboſa).*

*Bulbous Siſyrinchium.*] Hath a double bulbous root, growing one upon another; crowned with long, narrow, channelled, ſharp-pointed leaves; and an upright firm flower-ſtalk, half a foot high, terminated by two or three ſmalliſh blue flowers; appearing in ſummer.

*Variety*] With yellow ſpotted flowers.

This ſpecies is alſo proper furniture to encreaſe the variety of bulbous-rooted flowers;

and its culture and propagation is the ſame as the two former ſpecies of bulbous Iris.

ITEA, *Itea.*

One ſpecies only, a hardy deciduous flowering ſhrub, conſtitutes this genus, and is proper for the ſhrubbery.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is monophyllous, acutely five-parted at top, and permanent. COROLLA, five long ſpear-ſhaped petals. STAMINA, five awl-ſhaped filaments, and roundiſh antheræ. PISTILLUM, an oval germen, cylindric permanent ſtyle, and obtuſe ſtigma. PERICARPIUM, an oval, long, unilocular capſule, terminated by the ſtyle, and contains many ſmall ſeeds.

The ſpecies is;

ITEA *Virginica.*

*Virginian Itea.*] Hath a ſhrubby ſtem, branching out irregularly all around from the bottom upward, ſix or ſeven feet high; ſpear-ſhaped, ſlightly-ſawed, alternate leaves; and all the branches and ſhoots terminated by long erect ſpikes of white flowers, making a fine appearance in July.

This beautiful ſhrub ſhould have a place in the moſt conſpicuous ſhrubbery compartments, for being ſo very floriferous as to appear covered with its bloom, continuing in great beauty a fortnight or three weeks.

It is propagated by ſeed and by layers.

The ſeeds arrive from America in ſpring, when they ſhould be ſowed in pots or boxes of light ſandy earth, and plunge them in the ground till next year in March; then, if the plants are not come up, plunge them in a hot-bed, which will greatly promote their growth, giving frequent waterings all the ſummer, and allow them the ſhelter of a frame or green-houſe the two firſt winters; then in ſpring after plant them out in nurſery rows a foot aſunder, and in two or three years, they will be ready for the ſhrubbery.

Layers of the young ſhoots made in autumn or ſpring, making a ſlit in the part to be layed, will be rooted by autumn following.

IVA, Jeſuit's-Bark Tree.

There are two ſpecies, one a hardy deciduous ſhrub for the ſhrubbery, and the other an herbaceous annual, but the former is the ſort principally cultivated.

Claſs and order, *Monoecia Pentandria.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant, having a roundiſh permanent cup, containing many florets. COROLLA, a compound convex flower, having many funnel-ſhaped male florets in the diſc, and the females are apetalous. STAMINA, five briſtly filaments, and erect antheræ. PISTILLUM, an oblong germen, two hair-like ſtyles, and acute ſtigmas. PERICARPIUM, none, ſolitary ſeeds lodged naked on the proper receptacle.

The ſpecies is;

IVA *Fruteſcens.*

*Shrubby Iva, commonly called Jeſuit's-Bark Tree.*] Hath a ſhrubby ſtalk and branches of ſlender growth, riſing eight or ten feet high; ſpear-ſhaped ſawed leaves; and monoecious pale purple flowers, in cluſters from the ends of the branches, in Auguſt or September, but no ſeeds in England.

It is an American ſhrub, but hardy enough to grow here in the open ground, and is proper for the ſhrubbery plantations, allowing it a dry ſoil, and ſheltered ſituation.

Its propagation is by layers and cuttings; lay the young branches in ſpring, and they will be rooted and fit to tranſplant in autumn; and plant cuttings of the young ſhoots in April or May, in a ſhady border, they will readily emit roots.

JUGLANS, Walnut-Tree.

This genus conſiſts of large, hardy, deciduous trees, eminent as fruit-trees, foreſt-trees, and for ornament, attaining from thirty to forty or fifty feet ſtature, branching into large very ſpreading heads, adorned with elegant pinnated leaves, and monoecious flowers in amentums and cluſters.

Claſs and order, *Monoecia Polyandria.*

*Characters.*] CALIX, male and female flowers apart on the ſame tree; the males in oblong, cylindric, ſcaly amentums, each floret having a ſcale for its cup; and female flowers in cloſe-fitting cluſters, with a four-pointed cup to each floret. COROLLA, in the males, is a ſix-parted plane floret, and in the females, is acute, four-parted, and erect. STAMINA, in the males many ſhort filaments, and acute erect antheræ. PISTILLUM, in the females, a large oval germen under the calix, two ſhort ſtyles, and large reflexed ſtigmas. PERICARPIUM, a large, oval, drupaceous, unilocular fruit, incloſing a large oval or roundiſh knotted, furrowed nut, nearly quadrilocular, having a four-lobed, furrowed kernel.

There are three ſpecies common to our Engliſh plantations, each comprehending ſome varieties, though the common walnut is

is that which is moſt generally cultivated, both as a fruit and timber-tree; all the others, however, are equally hardy, produce eatable fruit, though with much ſmaller kernels than the common ſort; therefore the common walnut is the moſt eligible for general culture for the fruit; but conſidered as ornamental and foreſt trees, all the ſorts are proper.

The ſpecies are;

[1]JUGLANS *Regia.*

*Common Walnut-tree.*] Grows fifty feet high, or more, with a large upright trunk, branching into a very large ſpreading head; large pinnated leaves, of two or three pair of oval, ſmooth, ſomewhat ſerrated lobes, terminated by an odd one; and monoecious flowers; ſucceeded by cluſters of large green fruit, encloſing furrowed nuts of different ſhapes and ſizes in the varieties; ripen in September and October.

*Varieties are.*] Common oval Walnut—round Walnut—large Walnut—ſmall-fruited Walnut—double Walnut—early Walnut—late Walnut—tender thin-ſhelled Walnut—hard thick-ſhelled Walnut.

There are ſome other ſeminal variations, for plants raiſed from the nuts of the ſame tree, will often produce different varieties of fruit, as is common with moſt other fruit-trees. The wood, leaves, and outer covers of the fruit of all the varieties of this ſpecies is extraordinary bitter, and the ſkin of the kernel is a ſtrong bitter aſtringent, which ſhould be peeled off, the kernel then eats very palatable with an agreeable flavour.

[2]JUGLANS *Nigra.*

*Black Virginian Walnut.*] Grows forty or fifty feet high, with a large trunk, and very branchy ſpreading head; large pinnated leaves, conſiſting in different varieties, of from five or ſix to ten or twelve ſpear-ſhaped, ſawed lobes, terminated by an odd one, the lower lobes the leaſt; and monoecious flowers, ſucceeded by rough hard-ſhelled nuts, differing in ſhapes and ſize in the varieties.

*Varieties are.*] With round fruit——with oblong deeply-furrowed fruit—with aromatic-ſcented leaves.

[3]JUGLANS *Alba.*

*White Virginia Walnut, commonly called Hickory Nut.*] Grows thirty feet high, having pinnated leaves, which, in different varieties, conſiſt of from two or three to ſix or ſeven pair of ſpear-ſhaped ſawed lobes, terminated by an odd one; and monoecious flowers; ſucceeded by oval ſmooth nuts, having a whitiſh ſhell.

*Varieties of this are.*] Smooth-barked white Virginia Walnut——ſhag-bark white Virginia Walnut, having the ſtem and older branches covered with a rough ſcaley bark—with large fruit—with ſmall fruit.

The flowers of all theſe trees are male and female apart on the ſame plant; the males commonly in oblong cylindric katkins, and the females in cloſe cluſters, appearing generally in April and May; ſucceeded in the females, by large roundiſh green fruit, each including one nut, having a hard ſhell filled with an eatable kernel; but thoſe of the common Walnut are the largeſt and fineſt flavoured; all of them ripening in September and October.

All the three ſpecies and reſpective varieties are very hardy, and proſper in any common ſoil; they are all deciduous; their leaves come out in May, and fall off in October and November.

They are all employed occaſionally in plantations, both as foreſt-trees for timber, and to intermix in plantations for ornament, and the *Juglans Regia* alſo as a fruit-tree; all the ſorts are alſo peculiarly adapted to plant as detached ſingle objects in parks and paddocks, as having very large, regular ſpreading heads; they have likewiſe a fine effect diſpoſed in groups of three or more trees together at ſufficient diſtances from one another for their heads to ſpread; and are alſo proper to uſe in aſſemblage to form avenues, and to plant in hedge rows, in the boundaries of fields and other open places, for they will thrive either on plains, the ſides of hills, or in vales, in almoſt any ground, but delight moſt in a loamy ſoil.

They are all of large ſpreading growth; but the firſt and ſecond ſpecies are the largeſt growers; their trunks acquire a conſiderable ſtature and ſubſtance, and divide into very large arms, forming monſtrous ſpreading heads, particularly the common Walnut; the black Virginia Walnut, however, grows rather the moſt upright.

Conſidered as foreſt or timber-trees, they are alſo all very proper to be admitted of that tribe, and placed among the hardy deciduous kinds, for their timber is valuable for many purpoſes; not, however, where ſtrength is neceſſary, it being of a very brittle nature, but the cabinet-makers and joiners eſteem it

greatly for ſeveral ſorts of houſhold furniture, and other light works, for the wood being beautifully veined, takes a fine poliſh, and the more knotty it is, the more it is valued for particular purpoſes.

With reſpect to their merit as fruit-trees, all the ſorts produce fruit here, but the common Walnut the largeſt, moſt plentiful, and fineſt eating; the others having very ſmall kernels. The common Walnut-tree, therefore, is the only proper ſpecies of *Juglans* to cultivate as a fruit-tree for the ſake of the Walnuts; and it may be planted as ſtandards in orchards, like other fruit-trees, but at a greater diſtance, as having large ſpreading heads; or, are well adapted for planting round the boundaries of orchards, where they will alſo guard the other leſſer fruit-trees from boiſterous winds; and may be planted as fruit-trees in parks or paddocks, and in rows round fields, or in any open place where thought convenient; they are raiſed plentifully from the nuts, and planted out in nurſery rows, as directed below; and in five or ſix years the plants will be ſix or eight feet high, with firm ſtems and handſome heads, when they may be planted out where they are to remain; though the younger theſe trees are planted out, the better they will ſucceed; or if the nuts were planted at once where the plants are always to ſtand, the trees would ſtill be of more quick and larger growth; obſerving in either mode of planting, that as the trees branch out into very ſpreading heads, they ſhould ſtand thirty or forty feet each way aſunder; planting them with their heads entire, and ſuffer their branches and ſhoots always to advance according to their own natural growth, without ſhortening; for the trees produce their fruit on the young ſhoots ariſing towards the extremity of the branches, ſo ſhould never be ſhortened except in caſes of very irregular growth, or great ramblers. See STANDARD FRUIT-TREES.

It is, however, a common opinion, that beating theſe trees with large poles to get down the fruit, (which conſequently breaks many of the ſhoots) promotes their bearing; the only reaſon that can be aſſigned for this opinion is, that the trees producing their fruit upon the young ſhoots of the laſt and ſame year, as aforeſaid; and that by beating the branches with long poles, as the moſt expeditious way of gathering the fruit from large trees, it breaks off many older ſhoots, alſo the ends of many of the young ones, which probably, like ſhortening with a knife, forces out a greater ſupply of young ſhoots the following year for bearing. I ſhould, however in the operation of beating down the fruit, be for ſaving the branches as much as poſſible.

Theſe trees ſeldom begin to bear fruit till they are ſeven or eight years old, but never any conſiderable quantity till they are treble that age, when they have formed large heads.

The fruit is uſed at two different ſtages of growth; when green, to pickle; and when ripe, to eat raw.

As a pickle, the young green walnut, when about half or near three-parts grown, before the outer coat and ſhell becomes hard, is a moſt excellent vegetable pickle; and for which purpoſe they are generally ready in July and Auguſt, obſerving that for this uſe they muſt be gathered by hand, chuſing ſuch as are as free from ſpecks as poſſible.

The ripe fruit will be fit in the latter end of September and October, which, as before noticed, is commonly beat down with long poles, eſpecially on large trees, for as the Walnuts grow moſtly at the extremity of the branches, it would, in large trees, be troubleſome and tedious work to gather them by hand. As ſoon as gathered, lay them in heaps a few days to heat and ſweat, to cauſe their outer huſks, which cloſely adhere, to ſeparate from the ſhell of the nuts; then clean them from the rubbiſh, and depoſit them in ſome dry room for uſe, covering them over cloſe with dry ſtraw, half a foot thick, and they will keep three or four months.

Walnuts are always ready ſale at market, eſpecially thoſe of London, where at their firſt coming in, they are brought with their huſks on, and ſold by the ſack, or buſhel, but afterwards are brought clean, and ſold both by meaſure and by the thouſand.

Thus plantations of Walnut-trees are profitable in their annual crops of fruit while growing, and in their timber when felled.

*Propagation of all the Sorts.*

The propagation of all the ſorts of theſe trees, is moſt commonly by planting the nuts, which grow freely in beds of common earth.

For thoſe of the common Walnut intended for fruit-trees, the beſt varieties of nuts ſhould be procured, ſuch that are large, thin-ſhelled, and with the fineſt flavoured kernels; for although the fineſt ſorts will vary or degenerate

nerate, yet by planting only the very beſt, there will be the greater chance of having a ſucceſſion continued without much degeneracy.

Having procured the nuts at the proper ſeaſon, when perfectly ripe, in their outer cover or huſks, if poſſible; they ſhould be preſerved in dry ſand until February, and then planted: at which time having the ground dug, draw drills two inches and a half deep, and a foot aſunder, in which plant the nuts four or five inches apart, and cover them over with the earth; they will come up the ſame ſpring, and by the end of ſummer the young plants will be half a foot or more high, which, after having two years growth in the ſeed-bed, plant them out in the nurſery; previouſly, when taken up, ſhorten their tap-roots, but preſerve their tops entire, and plant them in rows two feet and a half aſunder, and about eighteen inches diſtant in each row: here they are to remain a few years, training them with ſingle ſtems, till five or ſix feet high, or a little more or leſs, then tranſplant them where they are finally to remain.

Thoſe intended principally as timber trees as well as to bear fruit, ſhould be always planted out for good when from three to four or five feet high, or if the nuts were planted at once where the trees are deſigned to remain, without tranſplanting, they would aſſume a quicker and ſtronger growth.

The nuts of the ſecond and third ſpecies, are annually ſent hither from America, and may be had of moſt of the nurſery-men and ſeed dealers; they commonly arrive in ſpring, and ſhould be ſowed as ſoon as poſſible after their arrival, in the ſame manner as directed for the common Walnut.

JUNIPERUS, Juniper, and the *Cedrus* and *Sabina*.

This genus furniſhes beautiful ever-greens of the ſhrub and tree kind, for ornamental plantations, growing from three or four to thirty or forty feet high in different ſorts, often branchy to the very bottom, and of pyramidal growth; cloſely garniſhed with very ſmall narrow leaves, placed moſtly imbricatum, remaining all the year; and dioecious flowers, of no beauty, ſucceeded by ſmall berries.

Claſs and order, *Dioecia Monadelphia*.

*Characters.*] CALIX, male and female flowers on different plants; the males in a conical amentum, by threes, having broad ſcaly imbricated calices; and the females a ſmall three-parted cup placed on the germen. COROLLA, none in the males, and in the females three ſtiff permanent petals. STAMINA, three filaments, and three diſtinct antheræ PISTILLUM, a germen under the calix of the females, three ſtyles and ſimple ſtigmas. PERICARPIUM, a roundiſh fleſhy berry, having three ſeeds.

In this genus is retained alſo ſeveral of the *Cedrus*, or Cedars; and the *Sabina*, or Savin, of former botaniſts, which they ranged as diſtinct genera, but are found to be only ſpecies of the Juniperus. There are ſeveral ſpecies, all of them, except the common Juniper, are foreigners, but all tolerably hardy, ſucceed in the open ground, and are great ornaments to our ever-green plantations.

The ſpecies are;

[1]JUNIPERUS *Communis*.

*Common Juniper*. Of which there are the two following

*Varieties.*

*Common Shrubby Engliſh Juniper*.—Grows five or ſix feet high, branching cloſely from bottom to top; forming a very cloſe buſhy plant, thickly garniſhed with narrow, awl-ſhaped, acute-pointed, ſpreading leaves by threes; and ſmall yellowiſh flowers in ſpring; ſucceeded, in the female plants, by purpliſh berries, ripening the following year in autumn.

This variety grows wild in England upon barren heaths and commons, where it produces abundance of berries; but is cultivated in gardens, and trained for an ornamental ſhrub, to encreaſe the variety in ſhrubbery plantations.

*Swediſh Juniper*.—Grows ten or twelve feet high, very branchy the whole length, with the branches growing more erect, and leaves, flowers, and fruit like the former variety. Is a native of Sweden and Denmark.

[2]JUNIPERUS *Oxycedrus*.

*Oxycedrus, or Spaniſh Juniper*.] Grows ten or fifteen feet high, cloſely branched from bottom to top; ſhort, awl-ſhaped, ſpreading leaves by threes, and ſmall dioecious flowers, ſucceeded by large reddiſh-brown berries.

[3]JUNIPERUS *Thurifera*.

*Greater Blue-berried Spaniſh Juniper*.] Grows twenty feet high, or more, branching in a conic form, acute imbricated leaves by fours, and ſmall dioecious flowers, ſucceeded by large blue berries.

[4]JUNI-

[4]Juniperus *Virginiana.*

*Virginia Cedar.*] Grows thirty or forty feet high, branching from bottom to top, in a conic manner; ſmall leaves by threes adhering at their baſe, the younger ones imbricated, and the old ones ſpreading; and dioecious flowers, ſucceeded by ſmall blue berries.

[5]Juniperus *Lycia.*

*Lycian Cedar.*] Grows twenty feet high, branching erectly, garniſhed with ſmall oval, obtuſe leaves, every where imbricated; and dioecious flowers, ſucceeded by large oval brown berries. Is a native of Spain and Italy.

[6]Juniperus *Phœnicea.*

*Phœnician Cedar.*] Grows about twenty feet high, branching pyramidically; adorned with ternate and imbricated obtuſe leaves; and dioecious flowers; ſucceeded by ſmall yellowiſh berries. Is a native of Portugal.

[7]Juniperus *Bermudiana.*

*Bermudian Cedar.*] Grows twenty or thirty feet high; has ſmall acute leaves, by threes below, the upper ones awl-ſhaped, acute, and decurrent, by pairs or fours, ſpreading outward; and dioecious flowers, ſucceeded by purpliſh berries. Is a native of Bermudas.

[8]Juniperus *Sabina.*

*Sabina, or Savin-tree*; Of which there are the following

*Varieties.*

*Spreading Savin.*—Grows but three or four feet high, with horizontal very ſpreading branches; ſhort, acute-pointed, decurrent, erect, oppoſite leaves; and dioecious flowers, ſucceeded by blueiſh berries; but very rarely produces either flowers or fruit.

This variety is uſed in medicine; and it is ſaid the juice of the leaves mixed with milk and honey is excellent for expelling worms in children; and a poultice thereof cures ſcald heads; the juice of it is alſo ſaid to clear the face from freckles; and the farriers eſteem it greatly for deſtroying worms in horſes, it being a powerful operator that way; and its virtues are accounted excellent for many other diſorders.

*Upright Savin.*—Grows eight or ten feet high, with upright branches, dark-green leaves, nearly like the former ſort, and dioecious flowers, ſucceeded by plenty of berries.

*Variegated Savin.*—Having the ends of many of the the ſhoots and young branches variegated with white, and the leaves finely ſtriped, the whole appearing very beautiful.

All theſe ſpecies of *Juniperus* are very pretty ever-greens, of the tree and ſhrub kind, moſtly of pictureſque growth, branching out all around cloſely from bottom to top; all of them very cloſely garniſhed with leaves, which although in general very ſhort and ſmall, yet are ſo numerous and thickly ſet, that the plants appear every way very cloſe and beautiful; and all the ſorts are excellent furniture for all ornamental plantations, where they will have a fine appearance at all ſeaſons of the year, as being always cloathed with leaves; but as to their flowers, they have no beauty, except to the botaniſts for obſervation; and as to fruit, the common Junipers produce plenty, alſo ſome of the others; but the Cedars rarely furniſh many berries in England; nor do the ſpreading Savin, though the upright kind often produce ſuch plenty as to have a very agreeable effect on the plants.

They all ſucceed in the open ground, and will grow in any common ſoil and ſituation, in common with other hardy trees, though they are rather the moſt proſperous in a light ſandy ſoil.

In diſpoſing all theſe kinds of plants in the ſhrubbery plantations, good attention ſhould be had to arrange them according to their degrees of growth, ſo as to exhibit a regular gradation of height, placing the low-growing ſorts, ſuch as the *Juniperus Communis*, and the Savin kinds, towards the front; and the other larger growers more backward in proportion to their ſeveral ſtatures, placing all of them in aſſemblage with other ornamental ſhrubs and trees, principally of the evergreen tribe.

Some of the large-growing ſorts may alſo be introduced into the foreſt-tree plantations; as in their native countries they afford excellent timber for many uſes, more particularly the Virginia cedar, which alſo arrives to a conſiderable ſtature here, eſpecially if the under branches are trimmed off occaſionally while young, to promote their aſpiring in height; they will grow very ſtraight, with fine regular heads.

Moſt of theſe ſpecies of *Juniperus*, emit a ſtrong aromatic balſamic odour, and abound more or leſs with a reſinous juice of ſo exceedingly bitter quality, as to prevent the timber, when converted to oeconomical uſes, from being eaten and deſtroyed by vermin.

*Propagation of all the Sorts.*

The propagation of all the Juniper and Cedar kinds, is by ſeed; and the Savins principally by layers and cuttings; but may likewiſe be raiſed from the berries, if they can be procured; and the ſeeds of all the ſorts are to be ſowed in beds of common light earth, except the Cedar of Bermudas, which muſt be ſowed in pots, to have ſhelter in winter.

The ſeeds of all the ſorts may be had at moſt of the nurſeries and ſeedſmen; obſerving that thoſe of all ſuch ſorts which can be procured in autumn, ſhould be ſowed at that ſeaſon, whereby they will more certainly come up the ſpring following; but thoſe that are not ſowed till ſpring, generally remain in the ground till that time twelvemonth, before they germinate or ſprout, unleſs aided by a hot-bed. Some of the ſorts, however, rarely produce much ſeed here: it is procured annually from the countries where the trees naturally grow, by the ſeedſmen, commonly arrives early in ſpring, and ſhould be ſowed as ſoon after their arrival as poſſible.

All the ſorts, except the Bermudas Cedar, as before obſerved, are to be ſowed in beds of light earth, in the full ground. Having dug the ground, and raked it fine, ſow the ſeeds evenly on the ſurface, and cover them with fine earth half an inch deep. Thoſe ſowed in autumn, will many of them come up in April or May following; but the ſpring ſowings will rarely appear till the following Spring. In either caſe, however, keep the beds clean weeded all ſummer; and thoſe plants that are up, now and then watered. When they have had two years growth in the ſeed-bed, plant them out, in autumn or ſpring, in nurſery rows, two feet aſunder, there to remain till of due ſize for final tranſplantation into the ſhrubbery, &c.

The Bermudas Cedar, as above noticed, being tender, it ſhould be ſowed in pots or tubs of light earth, to be moved under a frame in winter to be ſheltered from froſt; and when the plants are a year or two old, plant them in ſeparate ſmall pots, to be ſheltered alſo in winter three or four years, till they have acquired ſome ſize and ſtrength, then turned out of the pots into the full ground where they are to remain, in a warm ſituation, where let them take their chance, though a ſhelter of mats for the firſt winter or two during hard froſts will be of great ſervice.

The ſeaſon for tranſplanting all the ſorts is either in autumn, October or November, or in March and early in April.

JUSTICIA, *(Adhatoda)* Malabar nut.

It conſiſts of ſhrubby and herbaceous plants, of the Indies, for the green-houſe and ſtove, adorned ſome with fine large leaves, others with ſmall narrow foliage, and all of them with monopetalous ringent flowers.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is ſmall and acutely five-parted at top. COROLLA, is monopetalous and ringent. STAMINA, two awl-ſhaped filaments, and erect antheræ. PISTILLUM, a turbinated germen, ſlender ſtyle, and ſimple ſtigma. PERICARPIUM, an oblong bilocular capſule, opening with elaſtic force, and dart out their roundiſh ſeeds.

There are many ſpecies but not more than two common to the Engliſh gardens, both of them of the ſhrub kind for the green-houſe, viz.

[1]JUSTICIA, *Adhatoda.*

*Adhatoda, commonly called Malabar-nut.*] It grows twelve or fifteen feet high, with a ſtrong woody ſtem, branching out widely all around; large lanceolate oval leaves, placed oppoſite; and from the ends of the branches ſhort ſpikes of white flowers, with dark ſpots, having the helmet of the corolla concave.

[2]JUSTICIA *Hyſſopifolia.*

*Hyſſop-leaved Juſticia, or Snap-tree.*] Hath a ſhrubby ſtem, branching from the bottom pyramidally three or four feet high; ſpear-ſhaped, narrow, entire leaves, growing oppoſite; and white flowers, commonly by threes, from the ſides of the branches; ſucceeded by capſules, which burſts open with elaſtic force, for the diſcharge of the ſeeds. Hence the people of India call it Snap-tree.

Both theſe ſpecies flower here in ſummer, but never produce fruit in theſe parts.

They are natives of India, ſo are tender and muſt be kept in pots of light rich earth, and placed in a good green-houſe in winter, or may be placed in a hot-houſe, particularly the ſecond ſort; though they will both live in the open air in ſummer, and in a warm green-houſe in winter, managing them as other ſhrubby exotics of that department.

The propagatton of both ſorts may be effected by layers and cuttings. The laying is per-

performed in ſpring, in the pots; and cuttings of the young ſhoots may be planted any time in ſpring or ſummer, in pots, and plunged in a hot-bed, or in the bark-bed in the ſtove, giving water, and occaſional ſhade from the ſun; they will readily take root.

IXIA, *Ixia.*

This genus conſiſts of herbaceous, tuberous and bulbous-rooted flowery perennials for the pleaſure-ground and green-houſe, growing a foot or two high, terminated by hexapetalous flowers.

Claſs and order, *Triandria Monogynia.*

*Characters.*] CALIX, oblong permanent ſpathæ. COROLLA, ſix oblong, ſpear-ſhaped, unequal petals. STAMINA, three ſhort filaments, and ſimple antheræ. PISTILLUM, an oval triquetrous germen under the receptacle, erect ſtyle, and trifid ſtigma. PERICARPIUM, a roundiſh, three-cornered, trilocular capſule, having roundiſh ſeeds.

There are ſeveral ſpecies, the moſt material of which are:

*Hardy Kinds.*

[1]IXIA *Bulbocodium.*

*Bulbous Italian Ixia.*] Hath a ſmall bulbous root; crowned by ſeveral narrow leaves; and very ſhort flower-ſtalk, terminated by a large crocus-like flower, of different colours in the varieties.

*Varieties.*] With white and yellow flowers —with purpliſh and yellow flowers——blue and white flowers—white flowers—variegated flowers.

[2]IXIA *Chinenſis.*

*Chineſe Ixia.*] Hath a thick, tuberous, knotty root; upright jointed flower-ſtalk, two feet high; garniſhed with ſword-ſhaped leaves a foot long; and the ſtalk dividing upward into forks; ſuſtaining yellow red ſpotted flowers, remote, in forked panicles; appearing in July and Auguſt.

*Tender Kinds.*

[3]IXIA *Bulbifera.*

*Bulb-bearing Ixia.*] Hath a bulbous root; crowned with narrow leaves, ſix or eight inches long; and upright flower-ſtalks, a foot and a half high; garniſhed with leaves, bulbs growing at the joints; and terminated by ſulphur-coloured flowers, placed alternate.

[4]IXIA *Crocata.*

*Saffron-coloured Ixia.*] Hath a bulbous root; ſending up ſword-ſhaped leaves, near a foot long; and upright flower-ſtalks, a foot or more high; terminated by cluſters of deep yellow flowers, arranged alternate, having each a large black ſpot at the baſe; flowering in May.

[5]IXIA *Africana.*

*African Woolly-headed Ixia.*] Hath a ſmall bulbous root; ſending up very narrow leaves; a ſhort flower-ſtalk, three or four inches high; terminated by flowers collected into woolly heads.

The flowers of all theſe plants are compoſed each of ſix oblong petals, appearing in ſummer, and, in warm ſeaſons, ſome ſorts are ſucceeded by ripe ſeeds.

The plants are all permanent in root, but annual in leaves and ſtalk.

The two firſt ſpecies may be planted in the open borders; the ſecond, however, being rather tender, it ſhould have a warm ſituation; and ſome may be planted in pots to remove to ſhelter of a green-houſe or garden-frame in winter, in caſe thoſe in the open ground ſhould be killed by hard froſt.

The three other ſpecies muſt be planted in pots of rich light earth, for moving into the green houſe or garden-frame all winter.

All the ſorts propagate plentifully by offſets of their roots, which ſhould be taken off in ſummer at the decay of the leaves, &c.

---

# K.

KALMIA, *Kalmia.*

Of this genus are two hardy evergreen ſhrubs, for the pleaſure-ground, growing four or five feet high; adorned with oval, and ſpear-ſhaped entire leaves, and monopetalous, five-parted, in cloſe round bunches.

Claſs and order, *Decandria Monogynia.*

*Characters.*]

*Characters.*] CALIX, is ſmall, five-parted, and permanent. COROLLA, is monopetalous, with a cylindric tube, and the limb divided into five roundiſh ſpreading ſegments. STAMINA, ten filaments, and ſimple antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, a roundiſh quinquelocular capſule having numerous ſmall ſeeds.

The ſpecies are;

[1]KALMIA *Latifolia.*

*Broad-leaved Kalmia.*] Hath a ſhrubby branching ſtalk, growing five or ſix feet high; oval, ſtiff, ſhining green leaves, placed irregularly; and corymbus cluſters of pale-red flowers terminating the branches.

[2]KALMIA *Anguſtifolia.*

*Narrow-leaved Kalmia.*] Hath a ſhrubby ſtalk, dividing into many ſlender branches, growing four or five feet high; ſpear-ſhaped, ſtiff, ſhining green leaves, placed irregularly; and corymbus cluſters of bright-red flowers from the ſides of the branches.

Both theſe ſhrubs are beautiful ever greens, natives of America, but hardy enough to ſucceed any where in the open ground in this country.

They flower in June or July, the flowers collected into round, cloſe-ſitting, corymbus cluſters; each flower is of one petal, tubular below, and five parted and ſpreading above; and thoſe of both the ſpecies are very ornamental, but they are rarely ſucceeded by ripe ſeeds in England.

Theſe ſhrubs are elegant furniture for ornamental plantations, and ſhould be placed towards the front of the moſt conſpicuous ſhrubbery compartments.

Their propagation is by ſeed, ſuckers, and layers.

By Seed.—This arrives from America in ſpring: ſow it either in beds of light ground, or in pots or boxes of light ſandy earth, half an inch deep, and plunge them in an eaſterly border till ſpring following; and then, if the plants do not come up before, if the pots are plunged in a hot-bed it will forward them greatly; but innure them betimes to the full air all ſummer; and in winter give ſhelter from froſt, and when two years old, plant them in ſeparate pots, to move to ſhelter for two more winters, then let them be planted out in the full ground.

By Suckers,—The plants, after a few years ſtanding, ſend up ſuckers in tolerable plenty, which ſhould be taken off in ſpring, and planted in nurſery rows for two, three, or more years, to acquire ſtrength, then tranſplanted for good.

By Layers.—In autumn lay ſome of the young ſhoots of laſt ſummer, and they will be rooted in a year or two.

KÆMPFERIA, *Galangale.*

This genus conſiſts of low, herbaceous, flowery perennials of India, for the ſtove, adorned with radical, oval, and ſpear-ſhaped leaves, and monopetalous, tubular, ſix-parted flowers.

Claſs and order, *Monandria Monogynia.*

*Characters.*] CALIX, is obſolete, and placed above the germen. COROLLA, is monopetalous, with a long ſlender tube below, and ſix-parted above; three of the parts are ſpear-ſhaped, two are oval, and the loweſt is divided into two obcordate ſegments. STAMINA, one membranaceous ſuboval filament, and linear anthera, growing along the filament its whole length. PISTILLUM, an oval germen, ſimple ſtyle, and obtuſe ſtigma. PERICARPIUM, a roundiſh trilocular capſule, having many ſeeds.

There are but two ſpecies, both of low growth, and acaulous, i. e. having no ſtem; the leaves and flowers riſing directly from the root annually.

The ſpecies are;

[1]KÆMPFERIA *Galanga.*

*Galangale.*] Hath tuberous, thick, oblong, fleſhy roots; crowned with oval, cloſe-ſitting leaves, by pairs, four or five inches long, without foot-ſtalks, and between them cloſe-ſitting white flowers, with purple bottoms, growing ſingly.

[2]KÆMPFERIA *Rotunda.*

*Round Kæmpferia.*] Hath thick, fleſhy, ſwelling, roundiſh, cluſtering roots; ſending up ſpear-ſhaped leaves, ſix or eight inches long, near half as broad, on upright foot-ſtalks; and between them, immediately from the root, riſe whitiſh flowers, tinged with green, red, yellow, and purple centres.

Both theſe are perennial in root, but the leaves riſe annually from it in ſpring, and decay in winter.

They flower in ſummer; each flower is of one petal, tubulous below, but plain above, and divided into ſix parts; continue three or four weeks in beauty, but are never ſucceeded by ſeeds in England.

Both theſe plants muſt be potted in light rich mould, and always kept in the hot-houſe, giving plenty of water in ſummer, but more ſparingly in winter. They are propagated by

parting their roots in ſpring, juſt before they begin to puſh forth new leaves.

KIGGELARIA, *Kiggelaria.*

There is but one ſpecies, an ever-green ſhrub of Africa, retained here in green-houſe collections, for variety; and is a dioecious plant.

Claſs and order, *Dioecia Decandria.*

*Characters.*] CALIX, dioecious flowers, having monophyllous, five-parted cups. COROLLA, five ſpear-ſhaped, concave petals. STAMINA, ten ſmall filaments, and oblong antheræ. PISTILLUM, a roundiſh germen, five ſtyles, and obtuſe ſtigmas. PERICARPIUM, a globular, rough, unilocular capſule, having angular ſeeds.

The ſpecies is;

KIGGELARIA *Africana.*

*African Kiggelaria.*] Hath an upright woody ſtem, and purpliſh branches, growing fifteen or eighteen feet high; oblong, ſawed, alternate leaves; and dioecious, greeniſh-white flowers, in cluſters from the ſides of the branches; ſucceeded by globular rough fruit, the ſize of cherries, containing the ſeeds, which ſeldom ripen here.

This plant muſt be potted in rich garden-mould, and placed among the green-houſe plants, to have ſhelter in winter, managing it as other woody kinds.

It is propagated by ſeeds, layers, and cuttings, though both layers and cuttings root ſparingly.

Sow the ſeed in pots, and plunge them in a hot-bed, and when the plants are come up three or four inches high, plant them in ſeparate ſmall pots, plunging them alſo in the hot-bed till freſh rooted, then harden them to the full air the reſt of ſummer.

Layers ſhould be made in ſummer of the young ſhoots of the year.

And cuttings of the young ſhoots may be planted in ſpring in pots, and plunged in a bark-bed or other hot bed, and if cloſe covered with a hand-glaſs, they will more readily ſucceed.

KITCHEN-GARDEN, a principal diſtrict of garden-ground allotted for the culture of all kinds of eſculent herbs and roots for culinary purpoſes, &c.

A Kitchen-garden may be ſaid to be the moſt uſeful and conſequential part of gardening; ſince its products plentifully ſupply our tables, with the neceſſary ſupport of life, for it is allowed that health depends much on the uſe of a proper quantity of wholeſome vegetables, ſo that it is of much importance for every perſon poſſeſſed of a due extent of ground to have a good Kitchen-garden for the ſupply of his family. This garden is not only uſeful for raiſing all ſorts of eſculent roots and herbs, but alſo all the choicer ſorts of tree and ſhrub-fruits, &c. both on eſpaliers, wall-trees, and ſtandards; as the annual cultivation of the ground by manuring, digging, hoeing, &c. neceſſary in the culture of the eſculent herbs, alſo greatly encourages all ſorts of fruit-trees, preſerves them in health and vigour, ſo as always to produce large and fair fruit: for which reaſon, in the Kitchen-garden ſhould always be planted the choiceſt ſort of fruit-trees, particularly for walls and eſpaliers; likewiſe ſome ſtandards, if ſet a conſiderable way aſunder, ſo as not to ſhade the under-crops too much; and when the trees are judiciouſly diſpoſed, there will be almoſt equally the ſame room for the crops of herbaceous eſculents as without trees; ſo that this garden may be reckoned both as a Kitchen and fruit-garden.

As to the place of diſpoſition of this garden reſpecting the other diſtricts, if it is deſigned principally as a Kitchen and fruit-garden, diſtinct from the other parts, and there is room for choice of ſituation, it ſhould generally be placed detached entirely from the pleaſure-ground; alſo as much out of view of the habitation as poſſible, at ſome reaſonable diſtance, either behind it, or towards either ſide thereof, ſo as its walls or other fences may not obſtruct any deſirable proſpect either of the pleaſure-garden, park, fields, or the adjacent country; having regard, however, to place it, if poſſible, where the ſituation and ſoil is eligible, as hereafter illuſtrated; and if its ſituation is unavoidably ſuch as to interfere with the pleaſure-gardens, ſo as its walls may be thought diſagreeable to view, they may be ſhut out from ſight by intervening plantations of ſhrubs and trees.

But as in many places they are limited to a moderate compaſs of ground, in others have ſcope enough, and require but a moderate extent of garden; that in either caſe, have often the Kitchen, fruit, and pleaſure-garden all in one; having the principal walks ſpacious, and the borders next them of conſiderable breadth; the back part of them planted with a range of eſpalier fruit-trees, ſurrounding the quarters; the front

front with flowers and ſmall ſhrubs; and the inner quarters for the growth of the Kitchen-vegetables, &c.

*The proper Situation, Soil, Water, Extent, &c.*

As to ſituation, on this head we can only obſerve in general, that both high and low ſituations, if the ſoil is proper, will produce good crops of eſculent herbage and fruits; though a moderately low ſituation, by being leſs expoſed to the influence of cold and violent winds, may ſuit winter and early crops, both of herbs and trees, better than high-lying ground, provided, however, it is moderately dry, and not too retentive of moiſture in winter. A ſituation having a moderate ſlope is very eligible for this purpoſe, as in ſuch a ſpot there will not be any danger of water ſtanding, nor of being too wet at any ſeaſon; and if it ſlopes toward the South, it is a moſt deſirable ſituation, as it will not only be better defended from the cold northerly winds, but its expoſure or aſpect inclining to the ſun, we may always expect to have the earlieſt crops; or if, when the ſituation allotted for this garden is in ſome parts high, or a little ſloping, and others low and moiſt, it may be ſome advantage, as the high or ſloping ground will ſuit for early crops, and for wintering ſeveral ſorts of plants that are impatient of copious moiſture in that ſeaſon, ſuch as lettuce, &c. and the low ground will be eligible for late ſummer crops, as peas, beans, cauliflowers, tranſplanted lettuce, and ſeveral others. However, as to choice of ſituation and ſoil, this is practicable in large eſtates; but where perſons are limited to a moderate ſpace, they muſt be content with ſuch as nature affords; obſerving in this caſe, that if the natural ſoil is of a proper temperament and depth, we need not be under any great anxiety about the ſituation, if it is moderately dry, and not apt to be overflowed in winter; even in that caſe, it may be remedied, or greatly helped, by digging two or three long narrow canals, and from theſe ſome under-ground hollow drains, the earth from which will help to raiſe the contiguous ground higher, and the water in the canals will be convenient for watering the plants. Remarking that a ſituation too wet in winter ſhould be guarded againſt as much as the nature of the place will admit, for in ſuch land we can never have early crops, nor will the fruit-trees be proſperous.

With reſpect to ſoil, (ſee EARTH); the ſoil for a Kitchen-garden, of all others, requires to be naturally good, of depth enough for the growth of the large perpendicular eſculent roots, as carrots, parſneps, red beet, horſeradiſh, &c. alſo for the growth of fruit-trees, a very material article; ſo that the proper ſoil for theſe general purpoſes, ſhould, if poſſible, be from about a foot and a half to three feet deep or more; but much leſs than a foot and a half depth will be a great diſadvantage; ſo much depends upon the quality of the ſoil for a Kitchen and fruit-garden, that where there is ſcope of ground to chuſe from, we cannot be too cautious at firſt in fixing on a proper ſpot, where the ſoil is good, and depth enough, as above, before gravel, clay, chalk or other bad ſoils are come at, which ſhould always be more particularly attended to when deſigned to furniſh the ground with a choice collection of fruit-trees, either for the walls, eſpaliers, or ſtandards; for without a due depth of good earth, theſe will neither bear well, nor be of long duration.

Different ſorts of ſoils are met with in different parts, as loamy, clayey, ſandy, &c. A loamy ſoil either of a brown or black colour, is the beſt that can be for this purpoſe, more particularly a light ſandy hazel loam, which always works pliable at all ſeaſons, not apt to be too wet and cloggy at every ſhower of rain, nor bind in dry hot weather; this ſoil, however, although the moſt common ſuperficial earth in this country, is not common to all parts. A clayey, ſtrong, ſtubborn ſoil is the worſt of all earths, and muſt be mended by ſandy materials and coal-aſhes. A ſandy ſoil is common in many places, which if of a very light ſharp nature, it muſt be fertilized by plenty of rotten dung; and ſtrong earths where they can be eaſily procured.

It is obſervable that ground which conſtantly produces good crops of corn and graſs, is alſo proper for the growth of all eſculent herbs and fruit-trees.

Chuſe, however, the beſt ſoil you can, according to the ſituation and extent of your ground; and if it happens to prove unfavourable, art muſt aſſiſt; for if it is of a light ſandy nature, it may eaſily be mended, by adding ſtore of any kind of rotten dung; and if of a very light, ſharp, hungry tempera-

ment, earths of ſtronger ſubſtance, ſuch as loam, and the like, if it can be eaſily obtained, muſt be added occaſionally along with plenty of dung, working the whole with the natural ſoil of the garden; and ſhould your garden be of a clayey, cold, damp nature, add light materials, ſuch as any light ſandy ſoils; nothing is more proper than plenty of coal-aſhes, for opening and warming all tough, ſtubborn, cold ſoils; and theſe may be always procured in plenty almoſt every where, at an eaſy expence. See COMPOST, EARTH, &c.

Water is a very eſſential article in a Kitchen-garden in ſummer, to water all new tranſplanted plants, and others that cannot ſubſiſt without a due ſupply of moiſture during the drought of that ſeaſon; therefore, where practicable, one or more reſervoirs of of water ſhould be contrived in the moſt convenient part of the ground, either in baſons or narrow canals, and ſupplied with water from ſome contiguous ſpring, river, brook, pond, well, &c. See WATER.

The neceſſary ſpace of ground proper for a family Kitchen-garden, may be from about a quarter of an acre to ſix or eight, according to the extent and demand of the family, and the expence the proprietor would chuſe to beſtow on the making and general culture. A Kitchen-garden of an acre will nearly employ one man, eſpecially if it be furniſhed with wall and eſpalier trees to manage, and ſo in proportion to a garden of ſmaller or larger extent, a garden of the above ſize will produce a prodigious plenty of eſculent herbage and fruit, ſufficient at leaſt for a family of ten or fifteen perſons; but on large eſtates, where the family is conſiderable in proportion, three or four acres of Kitchen-garden may be neceſſary; and ſome very large families have them of ſix or eight acres extent.

*Fences for incloſing the Ground.*

With reſpect to fences for incloſing the ground, it is moſt neceſſary to have an effectual fence of ſome ſort around the Kitchen-garden, both for ſecurity of the produce, and to defend tender and early crops from cutting winds, and if wall-fences are uſed, they are alſo of the greateſt utility for training wall-trees, for producing the more delicate kinds of fruit, which do not acquire perfection in this country without ſuch aids.

Previous to fencing the ground, the proper ſhape or form for the garden is to be conſidered; the moſt eligible form for a Kitchen-garden, is that either of a ſquare, or oblong ſquare; but the figure may be varied, according as that of the ſituation admits; keeping, however, as near as poſſible to the ſquare, or oblong form, eſpecially if the ground is to be fenced with a wall for training fruit-trees; no other ſhape anſwers ſo well for that purpoſe; for trial having been made of circles, ovals, ſemi-circles, angles, &c. but none ſucceeded near ſo well as the ſquare form, with the walls built entirely ſtraight.

Different ſorts of fences are uſed for incloſing this ground, as walls, paling, and hedges.

But where wall-trees are intended, the beſt ſort of fence is a wall of brick or ſtone; but brick walls are conſiderably the beſt for training trees upon, for the joints of the brick-work being at ſhort regular diſtances, affords frequent opportunities for nailing the branches; beſides, the bricks themſelves will alſo often admit of the nails being driven into them; ſo that againſt brick-walls we may readily train trees in the moſt regular manner; but in default of bricks, and where ſtone-walls are intended, the ſtones ſhould be as regular as poſſible, and not too large, eſpecially in the front of the walls, that the joints may be at ſmall diſtances for the convenience of nailing, otherwiſe there will be an abſolute neceſſity of having a treillage of wood-work erected againſt the walls for nailing the branches to. See TREILLAGE.

Sometimes, to ſave expences in building brick or ſtone-walls, boarded fences, or paling is uſed, both as fences, and for training fruit-trees upon. When ſuch fences are intended for trees, the boarding ſhould be tongued and cloſely joined, edge to edge, and ſo as to form a plain or even ſurface, for the commodious training the branches.

In gardens where no wall-trees are intended, a hedge, or bank and hedge is a very proper fence, which may be ſo trained as to form both an effectual fence againſt men and beaſts, alſo to ſhelter particular parts of the ground for raiſing early crops; and a hawthorn hedge is the moſt proper ſort, though other ſorts may be uſed. See HEDGES.

No fencing, however, for a Kitchen-garden, where intended to have wall-trees, is equal to brick or ſtone walls, which is conſiderably

ſiderably ſtronger, warmer, and more durable than paling fences, and their natural warmth, together with their reflection of the ſun's heat, is the moſt effectual for the growth and ripening the more delicate kinds of fruit; but the brick walls are the warmeſt of all.

Either of theſe kinds of wall or paling-fences for fruit-trees, ſhould, where there is ſcope of ground, be ſo contrived as to have both ſides occupied with trees, which is effected by having a ſlip of ground taken in all round the outſide of the wall, or as far as may be convenient, about ten, twenty, or thirty feet wide, or more, incloſed with a bank and hedge (ſee HEDGES), or with any kind of paling, fencible againſt men and beaſts; which part, beſides its utility in affording an opportunity of planting the outſide of the wall, it will alſo be an addition to the Kitchen-ground, as it will ſerve for raiſing many ſorts of Kitchen-eſculents, and is often uſed as a ſort of nurſery, both for herbaceous and woody plants.

And in large gardens, where a great ſupply of wall-fruit is required, ſome croſs-walls may be run along the garden, at an hundred feet or more aſunder, but if more the better; both ſides of which may alſo be planted with trees, as obſerved of the boundary-wall.

The proper height for the walls, is from about eight to ten or twelve feet, but ten feet height will do tolerable well for moſt ſort of trees, provided you plant the trees at diſtance enough to have room to ſpread their branches horizontally each way; the walls, however, ſhould never be leſs than eight feet high. See WALLS.

Hot-walls for forcing by fire-heat, &c is often erected in large Kitchen-gardens; for an account of which, ſee FORCING FRAME and WALLS.

### *Preparing and laying out the Ground.*

The whole ground ſhould be regularly trenched two ſpades deep; obſerving if the ſoil is poor, or of bad quality, and wants amendment, either of dung, or any of the materials before mentioned, reſpecting the ſoil, it muſt be previouſly added, and trenched in betwixt the bottom and top ſpits, ſo as next year, when it comes to be digged again, the compoſt being well-rotted, will be worked up, and mixed with the natural ſoil. See DIGGING and TRENCHING.

Do not omit enriching and improving the borders for the wall and eſpalier-trees, by adding a conſiderable portion of rotten dung; and if the natural ſoil is not good, add alſo, if poſſible, ſome good loamy earth from the ſurface of a field or common, either to the whole, or rather than fail, a few barrows-full to each place where the trees are to ſtand; and improve the reſt afterwards by degrees at your convenience.

The ground muſt be divided into compartments for regularity and convenience. A border muſt be carried all round the boundary-walls, not leſs than four, but if ſix, eight or ten feet wide, the better, for the benefit of the wall-trees, that their roots may have full ſcope to run in ſearch of nouriſhment, for they generally run as far under ground as their branches extend in length, and by the annual digging and ſtirring the ground about them to ſome conſiderable breadth, greatly encourages the trees; hence the utility of having a broad border under the walls; next to this border a walk ſhould be continued alſo all round the garden, of due width, as mentioned below; then proceed to divide the interior parts into two, four, or more principal diviſions and walks, if its extent be large; firſt a ſtraight walk ſhould run directly through the middle of the garden; and another, if thought neceſſary, may be directed acroſs the ground, interſecting the firſt; and if the garden is of ſome conſiderable length, two, three, or more, ſuch croſs walks may be neceſſary; the width of the walks may be from about five to ten or twelve feet, in proportion to the extent of the garden; and each of the quarters ſhould be ſurrounded with a five or ſix feet wide border, and range of eſpaliers planted along towards the back-part of each border, ſo that every quarter will be incloſed with an eſpalier.

I would not, however, by any means adviſe dividing ſmall or moderate-ſized gardens into too many walks and ſmall quarters, eſpecially if they are to be ſurrounded with eſpaliers, which would render them too confined for the proper growth of culinary herbage; beſides it would be waſting too much of the ground in walks.

In one of the quarters a place ſhould be allotted for the melon-ground; that is, a place for making the hot-beds for raiſing early cucumbers, melons, and other tender plants, fixing on a ſpot for this purpoſe, full to the ſun from riſing to ſetting, ſheltered as much as poſſible from

from the northerly winds, and conveniently ſituated for bringing in the dung for the hot-beds.

This place, if not ſo ſituated as to be ſheltered by the walls, or other fences of the garden, will be of much advantage to incloſe it with a cloſe fence, either a reed-hedge, or paling; ſerving both to break off the winds, and by having a door to lock, will preſerve your crops more ſecure; theſe fences may be ſix or ſeven feet high in the back or north ſide, with both the ſide fences ſloping gradually to about five feet height in front; which ſhould always be loweſt to admit the ſun freely. See MELONARY.

With regard to the borders and walks of of this garden, the outer borders adjoining the walks ſhould be neatly formed, and the edges made firm and ſtraight, and the walks gravelled, or laid with other dry materials.

The edges of the borders are frequently planted with box, &c. eſpecially in gardens where the Kitchen and pleaſure-ground are all in one; ſometimes part are edged with underſhrubby aromatic herbs, as thyme, ſavory, hyſſop, and the like; but unleſs theſe are kept low and neat, they appear unſightly; ſome, however, uſe no planted edgings at all in proper Kitchen-gardens, only have the edge of the border made up even, treading it firm that it may ſtand, then cut it ſtraight by line; ſometimes along the top of this edging is planted a row of ſtrawberries, a foot or fifteen inches aſunder, they will bear plentifully, and have a good effect; obſerving to ſtring them ſeveral times in ſummer, to preſerve them neat and within due compaſs. See FRAGARIA.

The walks ſhould principally be laid with gravel, or good binding ſand, or nothing better than road-ſtuff, i. e. the wet ſoil of turnpike-roads, raked and ſhovelled up by the road-people in moiſt weather, in heaps; which being the ballaſt or ſtones uſed in repairing the roads, ground to pieces, and after having lain ſome time to dry, then brought in, it will form exceeding good walks for the Kitchen-garden; or, for want of either of the above materials, may uſe coal-aſhes, which, if the black colour can be diſpenſed with, will make a tolerably firm dry walk.

Sometimes graſs-walks are uſed, but theſe are rather improper for general uſe in Kitchen-gardens, eſpecially in ſuch parts of the garden where wheel-barrows are obliged to come often, which would cut and greatly deface them; beſides, they are apt to be wet and diſagreeable in all wet weather, and in winter; but if any are intended for variety and ſummers walking, they ſhould be only in ſome high dry part of the garden, and never let them be general, for beſides the afore-mentioned inconveniences, they are apt to harbour ſlugs and other crawling vermin, to the detriment of the adjacent crops.

The wall trees ſhould be planted at from fifteen to twenty feet diſtance, according to the ſorts. For peaches, nectarines, plums, and cherries, fifteen or eighteen feet is the proper diſtance; but for pears twenty feet is requiſite: obſerving to plant the choicer and more delicate ſorts on the beſt expoſures, ſo as to have the moſt ſun, as is expreſſed under their proper articles. Where practicable, always plant both ſides of the wall; and if you would have the walls covered as ſoon as poſſible, if the walls are high, may plant firſt dwarfs as the principal furniture, then half ſtandards and full ſtandards alternately between the dwarfs; and whilſt the dwarfs cover the lower part, the ſtandards furniſh the upper: but are to be afterwards taken away by degrees as the dwarfs grow up. See WALL-TREES.

The eſpaliers ſhould be planted in one range round each quarter, about five or ſix feet from the outer edge of the border, and from about fifteen to twenty-five feet aſunder, according to the ſorts of fruit-trees you plant. See ESPALIERS.

Within the eſpaliers in the quarters, you may plant ſome ſtandard fruit-trees of the choicer ſorts, but at thirty or forty feet each way diſtant, that they may not ſhade the ground.

Likewiſe in the quarters may be planted the ſmall kinds of fruit-ſhrubs, as gooſeberries, currants, and raſberries, in rows ſo as to divide the quarters into breaks of twenty or thirty feet wide, or more, placing the buſhes nine feet aſunder in each row, and if they are kept ſomewhat thin, and ſpreading the way of the rows, in the manner of an eſpalier, they will not incumber the ground, and will bear very plentiful crops of large fruit. See their *Culture*.

In many places, however, as we formerly noticed, there is but a ſmall compaſs of ground, or ſo limited as to be obliged to have the Kitchen, fruit, and pleaſure-ground all in one, or at leaſt often all within the ſame general incloſure; in which caſes, if any part of the ground is required for ornament,

ment, a portion of it next the houſe, may be laid out in a lawn or graſs-plat, bounded with a ſhrubbery; beyond which have the Kitchen-ground, ſeparating it alſo from the other with ſhrubbery compartments: the Kitchen-garden may alſo be laid out with ornamental walks and borders, having a broad border all round next the walls; and next this, a walk from five or ſix to ten feet wide, carried all round the garden; another directly through the middle; and next the walks have a border of ſix or eight feet wide, carried round each quarter or principal diviſion; which border, if made ſloping from the front to the back-part, will appear better than if quite flat; planting a range of eſpalier fruit-trees along the back of the border, ſo as immediately to ſurround the quarters, allotting the outſide of the border for flowers, and ſmall flowering ſhrubs, having the edge planted with box or thrift; and the walks neatly laid with gravel, or other materials before mentioned; the inſide within the eſpaliers to be the Kitchen-ground, dividing it, if thought neceſſary, by rows of gooſeberry, currant, and raſberry plants.

But when neceſſary to have the whole ſpace of the Kitchen-garden employed for real uſe, no ground ſhould be loſt in ornamental borders and walks: have a border all round the boundary-fence, four or five feet wide, except the ſouth borders, which ſhould be ſeven or eight feet broad, becauſe of its great uſe for raiſing early crops; and have a walk round the garden, not more than a yard wide; allowing the ſame width for the middle-walks, or ſo as to admit of wheel-barrows paſſing to bring in the manure, &c. and may either have a four feet wide border all round each quarter, next the walks, or not, as you ſhall think proper; laying the walks neatly with any gravelly materials, or with coal-aſhes, ſo as to have dry walking, and wheeling with a barrow in all weathers.

*General Culture of the Ground.*

With reſpect to the general culture of the Kitchen-garden; it conſiſts principally in a general annual digging; proper manuring; ſowing and planting the crops properly; keeping the ground clean from weeds; and watering the crops occaſionally in ſummer.

As to digging; a general digging muſt be performed annually in winter or ſpring, for the reception of the principal crops: alſo as often as any new crops is to be ſowed or planted; remarking that the general digging for the reception of the main crops in ſpring, I ſhould adviſe to perform it always by trenching either one or two ſpades deep, beſides the paring at top, though, except for ſome deep-rooting plants, as carrots, parſneps, &c. one ſpade depth may be ſufficient for common trenching, unleſs on particular occaſions, to trench as deep as the good ſoil admits, to turn the exhauſted earth to the bottom, and the freſh to the top to renew the ſoil. However, the trenching only one ſpade deep will much more effectually renew the ſoil than plain digging; and by paring the top of each trench, two or three inches deep into the bottom, all ſeeds of weeds on the ſurface, are thereby buried ſo deep, that they cannot grow; and I ſhould likewiſe adviſe that the general digging be performed principally in winter, or early in ſpring; but would be much the better if ſome conſiderable time before the ſeaſon for putting in the crops, that the ground may have the advantage of fallow, to meliorate and enrich it; and always let the ground be trenched in rough ridges, that it way receive all poſſible benefit from the ſun, air, rains, froſt &c. as it is ſoon levelled down for the reception of ſeeds and plants. Plain digging, however, may be ſufficient for ſlight crops, eſpecially in ſummer or autumn: after the ground has been trench-digged in the general winter or ſpring digging. See DIGGING and TRENCHING.

As to manure, any kind of dung, or compoſt of dung and earth is proper; and if this could be ſuited to the nature of the ſoil, it might be the greater advantage; that is, for ground of a ſtrong, heavy, cold nature, have for manure, a compoſt of well-rotted dung, aſhes, or any ſandy earths, and if light ſandy ground, have the moiſteſt ſort of dung, and heavy earths; ſee COMPOST, &c. Though any kind of well-rotted dung will ſuit as proper manure for almoſt every ſoil, but none better than the dung of old hot-beds, which is the moſt common manure for Kitchen-gardens, it being horſe, or ſtable-dung, firſt uſed in hot beds, where it becomes rotted to a buttery temperament, of an extremely enriching quality, and ſuits almoſt all kinds of ſoil and plants; but well-rotted neats-dung is alſo very good, particularly for light grounds, or a compoſt of every kind, as horſe-dung, neats-dung, hogs-hung, farm-yard dung, or mulch, aſhes, lime-rubbiſh, ſaw-

ſaw-duſt, rotten tan, having lain together till well rotted, will make excellent manure. See COMPOST, DUNGS, &c.

The manuring, or dunging the ground, may be neceſſary every year or two, for all crops being of an exhauſting nature in every ſoil, the vegetative vigour of the ſoils muſt be ſupported accordingly by a proper application of manure; but once every other year, however, the ground in general will want amendment; tho' where there is plenty of dung, give it as far as it will go every year, eſpecially for the principal crops, ſuch as onions, cauliflowers, cabbages, &c. for as the different crops exhauſts the ſoil, the addition of dung fertilizes and renews it; which when duly applied in proper quantities, the various crops will not only be much finer, but arrive to earlier perfection than in poor ſtarved ground.

All manuring ſhould generally be performed in winter or ſpring, to be dug in at the general annual digging; taking opportunity of froſty or very dry weather to wheel in the dung for the principal manuring, as it may then be performed more eaſy and clean without clogging, or ſpoiling the walks, or tearing up the ground; laying it in heaps by barrows-full at equal diſtances; afterwards ſpread it evenly, and dig it in one ſpade deep, as directed under the articles DIGGING and DUNGS.

In regard to cropping the ground, the proper ſituation for, and method of raiſing the different plants is fully exhibited under their reſpective articles; we will therefore only hint here, that it is eligible to allot the drieſt, warmeſt, and moſt ſunny ſituation for the early crops, and the other parts for the main crops.

The borders under the ſouth walls are proper for raiſing the earlieſt plants, as early peas, beans, radiſhes, ſpinach, lettuce, carrots, ſmall ſallad-herbs, kidney-beans, &c. The eaſt and weſt borders for ſucceſſion of early crops; and the north borders, which being ſhady and cool, ſerve for raiſing, and pricking out many ſmall plants, ſlips, and cuttings in ſummer; though all theſe borders in every expoſure may be made uſeful at all ſeaſons. The borders next the eſpaliers is proper for crops of ſmall plants at all ſeaſons of the year, as lettuce, endive, ſpinach, ſmall-ſallad herbs, ſtrawberries, and ſeveral others, both to ſtand, and for tranſplantation; and by keeping all the borders conſtantly well furniſhed with various eſculents, diſpoſed according to their different growths; they, beſides their uſefulneſs, effect a delightful variety.

The borders, however, under the walls are by moſt authors ſtrictly prohibited from the growth of culinary plants, on a ſuppoſition of their robbing the trees of nouriſhment; but as the ſouth borders being ſo valuable for raiſing many early crops, ſuch as radiſhes, lettuces, ſpinach, ſmall ſallad-herbs, carrots, peas, beans, kidney-beans, &c. they ſhould not be loſt; in ſhort all the other borders will be extremely uſeful in their turn; and when the borders are properly manured every year or two, I never found any material inconvenience ariſe to the trees. Peas and beans are particularly forbid to be growed on theſe borders, it is probable they might be better without them; but if only the lower growing ſorts are cultivated, and theſe in wide rows, and not too cloſe to the trees, there will be but little danger of their being injured by the crops, eſpecially as above hinted, if care is taken to renew the ſoil with plenty of rotten dung.

In the internal parts, called the quarters, ſhould always be raiſed the larger principal crops, ſuch as cabbages, cauliflowers, broccoli, coleworts, peas, beans, kidney-beans, onions, leeks, carrots, parſneps, beet, potatoes, turneps, artichokes, celery, general crops of lettuces, ſpinach, horſe-radiſh, &c.

As many of the eſculent plants ſucceed beſt in rows, ſuch as peas, beans, cauliflowers, and all the cabbage kinds; tranſplanted lettuces, endive, potatoes, artichokes, Jeruſalem-artichokes, celery, and ſome others, particular regard is requiſite, that the rows are at a proper diſtance for the plants to have full ſcope to grow, as directed for each ſort under their proper heads; and would adviſe that all the tall growing ſorts, as peas, beans, kidney-beans, &c. have their rows ranging ſouth and north, if poſſible, that the ſun may ſhine on each ſide of the rows in its turn, as well as on the ground between the rows; both of which is of more advantage to the crops than may be generally imagined, for when the rows range eaſt and weſt, one row ſhades another, ſo that when the plants grow up, they cannot all receive an equal benefit of the ſun and air.

The great art in cropping a Kitchen-garden, is to make the moſt of every part of the ground, where neceſſary, by having every part

part well occupied, and as many crops annually as poſſible; the Kitchen-gardeners about London are very expert at this; they crop their ground ſo full, in ſuch regular order, often ſeveral crops coming forward at a time in the ſame ground, ſo contrived according to the growth of each ſort, that as one crop is going off, another is coming on ready to ſucceed it, and after that another; ſo that the ground is often in full crop great part of the year; the method of which is generally hinted in the culture of the reſpective ſorts under their proper heads.

With regard to the methods of ſowing and planting the different crops, ſome are ſowed in drills, ſome by broad-caſt on the ſurface, and the ſeeds either raked in, or the earth ſpread or ſifted over them; and as to planting out the different plants, it is moſt commonly done by dibble, and ſome ſorts in drills or trenches, as practiſed for aſparagus; ſee DRILL-SOWING, SOWING-SEED, PLANTING, TRANSPLANTING, DIBBLE, HOE, &c.

Deſtroying weeds is a moſt neceſſary culture in the Kitchen-garden, and which muſt be very particularly attended to in ſpring and ſummer, for the ſucceſs of the crops greatly depends upon that work; it may be performed both by hand and hoe, occaſionally; hand-weeding is proper for all cloſe-growing ſmall plants, that either do not require thinning at all, or are only to be thinned by degrees; but by hoeing, in many caſes where the plants ſtand wide in rows, the broad hoe muſt be applied, both as the moſt expeditious method of killing the weeds, and the moſt effectual for the benefit of the plants, by ſtirring the earth about them; likewiſe ſmall hoeing is effectual for many ſmall plants that require thinning, and are deſigned to be thinned either in part, or hoed out at once to their due diſtances, ſuch as onions, carrots, parſneps, beet, turneps, &c. ſee HOEING. Obſerving in either mode of deſtroying weeds, always proceed to it time enough before the weeds begin to ſpread much, or are above an inch high, then the work may be performed with eaſe and expedition, and to the great benefit of the crops, by having the weeds timely deſtroyed; always chuſing dry weather for deſtroying weeds by hoe; and in hoeing between plants in rows, ſuch as peas, beans, kidney-beans, cabbages, cauliflowers, &c. always in in the firſt and ſecond hoeing draw a little earth up about their ſtems or ſhanks, which will greatly ſtrengthen the plants, and forward their growth.

The utmoſt attention is neceſſary never to ſuffer weeds to ſtand to perfect their ſeeds in any part, whether in crop or vacant, or on dung-hills, or compoſt heaps, as they would lay the foundation of ſeveral years trouble to extirpate them, for as in digging or hoeing the ground, ſome of the ſeeds would be buried near the ſurface, others much deeper, at every time of ſtirring the earth a freſh crop of weeds would ariſe from the ſame ſeeds, which verifies the ſaying, "One year's ſeeding, makes ſeven years weeding."

When weeds, however, are unavoidably ſuffered to grow large, or greatly advanced towards ſeeding, and are pulled up, or hoed down, let them, if poſſible, be carried off the ground, as many ſorts will often flower and perfect their ſeeds as they lie, particularly the downy-ſeeded kinds.

And with reſpect to root-weeds, i. e. thoſe with perennial roots, ſuch as bear-bind, couch-graſs, &c. the roots of which, and all others particularly of the like creeping growth, ſhould be carefully picked out, at every time of digging the ground, for the leaſt bit will grow and greatly increaſe; and in ſpring or in ſummer, as often as they ſhoot above ground, ſhould be pulled up, or where the hoe can come, deeply hoed, which if often repeated in dry weather, will greatly diminiſh them.

Watering the Kitchen-garden is only neceſſary in warm dry weather, to particular plants, more eſpecially to all thoſe newly tranſplanted; this in particular ſhould never be omitted, where practicable, for by giving each new-ſet plant directly ſome water, it ſettles the earth cloſe about their roots, they ſooner ſet to growing freely, and eſtabliſh themſelves firmly; and in hot dry weather, the watering ſhould be repeated every day or two for a week, till the plants have taken new root, and ſet to growing afreſh. Watering is alſo often requiſite in dry weather in the latter part of ſpring and during the ſummer ſeaſon, to beds of new-ſowed ſmall ſeeds; alſo after they come up, if the dry hot weather continues. Some ſorts of plants require continued occaſional waterings throughout the ſpring and ſummer ſeaſons, ſuch as all plants in hot-beds, as cucumbers, &c. as directed under the reſpective articles. In performing the watering, that for new tranſplanted plants

in wide rows, is commonly performed with the roſe, or the head of the ſpout of the pot off, giving it only juſt about each plant; though if all the ground is occaſionally watered, it will be the more beneficial to the plants. However, where the plants ſtand cloſe, either tranſplanted, or ſeedlings in the ſeed-bed, the watering ſhould be performed with the head of the pot on, giving it all over the plants, ground and all; obſerving in watering beds of ſmall ſeeds, or ſmall ſeedling plants, not to water too heavy or haſtily, leſt it waſh the ſeeds or plants out of the ground.

All general watering in ſummer, in hot ſunny weather, ſhould be performed principally in a morning or afternoon, that the moiſture may have time to ſoak to the roots of the plants before it is exhaled by the ſun's heat.

Neatneſs ſhould alſo be obſerved in the Kitchen-garden as well as in the pleaſure-ground, though not with that elegance as neceſſary in the latter; only a common uſeful neatneſs; for a well kept Kitchen-garden is to many as agreeable to walk in as the fineſt flower-garden; keep, therefore, all the walks particularly, and the principal outward borders clean from weeds, and all manner of rubbiſh, not ſuffering the decayed uſeleſs ſtalks and leaves of plants to remain; the ſame ſhould alſo be obſerved of the quarters or internal diviſions, clearing off all decayed cabbage-leaves, decayed peas and bean-ſtalks, artichoke-leaves, and other large rubbiſhy matter, which, beſides their littering appearance, ſome ſorts, ſuch as the decayed leaves of all the cabbage kinds, artichokes, &c. are apt to emit diſagreeable ſmells, and harbour ſlugs and other crawling vermin; ſo ſhould always be cleared off, eſpecially in gardens where company often walk.

And as crops are cleared off the ground, always broad-hoe it to cut up all the weeds, and if the weeds are large, it is proper to rake them off, eſpecially if it is like to be wet weather, but if dry and ſunny they will ſoon die.

In autumn and winter as the ground becomes vacant from crops, manure ſuch as require it, and trench the ground up in ridges, previous to ſpring cropping, for it greatly improves all ground to lie thus expoſed to the weather ſome months before it is ſowed or planted.

*Kitchen-garden Plants.*

KITCHEN-GARDEN PLANTS. Having given directions above for the making and general culture of the Kitchen garden, a liſt of the principal plants neceſſary to furniſh ſuch gardens, will, we preſume, be proper in this place; which notwithſtanding their being all fully treated of under their reſpective genera, yet by collecting them into one point of view, with ſhort hints of their method of propagation, will greatly aſſiſt the memory of every one, in furniſhing his garden at the proper ſeaſon.

We will exhibit each ſort under its generical botanic name, viz.

AGARICUS *campeſtris*.—Field agaric, or muſhroom. Propagation by ſpawn of the root, running in lumps of earth or dung. Autumn the proper ſeaſon.

ALLIUM, garlick, onion, leek, &c. The ſorts are:

ALLIUM *ſativum*, manured garlick, of which there are—large white garlick——red garlick. Propagation by the cloves of the root.

ALLIUM *ſcorodopraſum*, rocambole. Propagation by the root and bulbs from the ſtalk.

ALLIUM *cepa*, the onion—common oval Straſburgh onion—great oval Portugal onion—flat white Spaniſh onion—flat red Spaniſh onion—ſilver-ſkinned onion—bulbleſs-rooted Welſh onion. Propagation of all by ſeed annually.

ALLIUM *ſchænopraſum*, chives, or cives. By dividing the roots.

ALLIUM *aſcalonicum*, eſcalot, or ſhallot. By off-ſets of the root.

ALLIUM *porrum*, the leek—broad-leaved London leek—narrow-leaved leek. By ſeed annually.

ANETHUM, *dill*, &c. conſiſting of the following ſpecies.

ANETHUM *graveolens*, common dill. By ſeed annually.

ANETHUM *fœniculum*, fennel——light-green-leaved fennel—dark-green fennel——ſweet-ſeeded fennel. By ſeed, alſo by ſliping the old roots.

ANETHUM *finochia*, or Italian fennel. By ſeed annually.

ANGELICA *ſativa*, or *archangelica*—common angelica. By ſeed annually.

APIUM, parſley, celery, &c. conſiſting of the following ſorts:

APIUM,

APIUM *petroſelinum*, parſley—common plain-leaved parſley—curled-leaved common parſley—broad-leaved, or large-rooted parſley; the two former for their leaves, and the latter for its root. All raiſed by ſeed in ſpring.

APIUM *dulce*, celery—common upright celery—upright celery, with ſolid ſtalks——turnep-rooted ſpreading celery—ſmallage, or wild, rank-taſted celery.

ASPARAGUS *officinalis*, common aſparagus. By ſeed, and once raiſed the roots abide for years.

ATRIPLEX *hortenſis*. Garden orach—white-leaved garden orach—green orach—purple orach. By ſeed annually.

BETA *vulgaris*. The beet, of which there are;

BETA *cicla*, common culinary beet——green-leaved culinary beet——white beet——chard, or great white Swiſs beet. By ſeed annually.

BETA *ruba*, red beet—large, long, red-rooted beet—turnep-rooted red beet——red-rooted beet, with green leaves—pale-red beet; but thoſe with dark-red leaves and roots are the only ſorts for uſe. By ſeed annually.

BORAGO, *borage*. Some varieties. All raiſed by ſeed annually in autumn or ſpring.

BRASSICA, the cabbage, cauliflower, broccole, turnep, &c. The ſorts are:

BRASSICA *oleracea (Sylveſtris)* the cabbage, of which there are:—ſmall early ſummer cabbage—dwarf early ſugar-loaf-ſhaped cabbage——large, hollow, ſugar-loaf cabbage——early Ruſſia cabbage——common round white cabbage——long-ſided hollow cabbage——oval hollow cabbage—flat-topped cabbage—muſk-ſcented cabbage—giant cabbage—red cabbage. All by ſeed annually in ſpring and autumn, for uſe all the year.

BRASSICA *ſabanda*, ſavoy cabbage——common green curled ſavoy-——large green Dutch ſavoy—yellow ſavoy. By ſeed annually in ſpring, for autumn and winter uſe.

BRASSICA *laciniata*, laciniated, and other open-leaved cole—green curled borecole——red curled borecole——thick-leaved curled borecole—finely-fringed borecole——broad, erect, curled-leaved Siberian borecole, or Scotch cole, or kale, red and green—common plain-leaved green colewort; none of theſe ever cabbage, but always remain open and looſe quite to the heart; are remarkably hardy, and proper for winter uſe; all raiſed by ſeed annually in ſpring and ſummer.

BRASSICA *caulo-rapa*, turnep-cabbage—turnep-cabbage, with the turnep above ground—with the turnep under ground. By ſeed.

BRASSICA, *cauliflora*, the cauliflower—early cauliflower—late cauliflower. By ſeed annually in ſpring and autumn.

BRASSICA *Italica*, Italian *braſſica*, or broccoli—early purple broccoli—late large purple broccoli, comprehending ſome varieties, with blue, brown, green, and yellowiſh heads—white, or cauliflower-broccoli—black broccoli. All by ſeed in ſpring and beginning of ſummer, for autumn, winter, and ſpring uſe.

BRASSICA *rapa*, the turnep——early Dutch turnep—white round turnep—green-topped turnep—red-topped turnep——yellow turnep—oblong white turnep—long white-rooted French turnep—round purple French turnep. By ſeed in ſpring and ſummer, for uſe moſt part of the year.

CALENDULA *officinalis*, common officinal marigold, ſeveral varieties. By ſeed annually in ſpring, ſummer, or autumn.

CICHORUM *endivia*, endive—green curled endive——white curled endive—broad-leaved Batavia endive. By ſeed annually in ſummer, from May till July, for autumn and winter ſervice.

COCHLEARIA *armoracia*, horſe-radiſh. By pieces of the roots in ſpring, for uſe moſt part of the year.

CRAMBE, ſea-colewort. By ſeed in ſpring, but once raiſed the roots remain for years, ſending up ſhoots for uſe in ſpring and ſummer.

CUCUMIS, the cucumber and melon. The ſorts are:

CUCUMIS *ſativa*, the cucumber—early ſhort prickly cucumber—early cluſter-cucumber—long, green, prickly cucumber—long, white, prickly cucumber——long, ſmooth, green, Turkey cucumber——large, ſmooth, white cucumber—large, ſmooth, green, Roman cucumber. All by ſeed annually in ſpring and ſummer.

CUCUMIS *melo*, the melon——Romana melon——Cantaleupe melon; of each ſome varieties, and ſeveral other ſorts; ſee their *Culture*. By ſeed annually in ſpring.

CUCURBITA, the gourd and water melon, of each different ſorts; ſee CUCURBITA. By ſeed annually in ſpring.

CYNARA, artichoke and cardoon. The ſorts are:

CYNARA *ſcolymus*, common artichoke, of which are—globular-headed, red Dutch artichoke.

choke—oval-headed, green French artichoke. By ſuckers from the ſides of the old plants in ſpring.

CYNARA *cardunculus*, the cardoon. By ſeed annually in ſpring.

DAUCUS *carota*, the carrot—orange-coloured carrot—red carrot—yellow carrot—white carrot. By ſeed annually in ſpring, ſummer, and autumn; for uſe moſt part of the year.

HELIANTHUS *tuberoſus*, tuberous ſunflower, or Jeruſalem artichoke. By pieces of the root in ſpring.

HYSSOPUS *officinalis*, common officinal hyſſop. By ſeed in ſpring, and by ſlips and cuttings of its branches.

LACTUCA, lettuce—early green cabbage-lettuce—white cabbage-lettuce—brown Dutch cabbage-lettuce——great admirable cabbage-lettuce—green and white ball-cabbage-lettuce—green coſs-lettuce—white coſs-lettuce—black coſs-lettuce—ſpotted Allepo coſs-lettuce—brown Sileſia lettuce—imperial lettuce—red capuchin lettuce—green capuchin lettuce—curled lettuce. All by ſeed annually in ſpring, ſummer, and autumn; for uſe moſt part of the year.

LAVANDULA, lavender. The ſorts are:

LAVANDULA *ſpica*, ſpike-flowered common lavender——common narrow-leaved—broad-leaved—blue flowered—white-flowered—and dwarf lavender. By ſlips in ſpring.

LAVANDULA *ſtœchas*, ſtœchas, or French lavender. By ſlips or cuttings, and by ſeed.

LEPIDIUM *ſativum*, garden-creſs—common ſmall-leaved—broad leaved——curled-leaved. By ſeed at different times of the year, according as the plants are wanted.

MELISSA *officinalis*, baum. By dividing the roots in ſpring or autumn.

MENTHA, mint, penny-royal, &c.

MENTHA *viridis*, green common ſpear-mint—curled-leaved ſpear-mint—variegated ſpear-mint. By dividing the roots, by young plants, and by cuttings of the ſtalks in ſpring.

MENTHA *piperita*, pepper-mint. By roots and plants, &c. like the former.

MENTHA *pulegium*, penny-royal. By dividing and ſlipping the plants, as for themint

OCYMUM *baſilicum*, baſil. Several varieties, ſee OCYMUM. By ſeed in ſpring.

ORIGANUM, marjoram—common, wild, perennial pot-marjoram——winter perennial ſweet-marjoram—marjorana, or annual ſweet-marjoram. By ſeeds in ſpring, and the two former alſo by ſlipping the roots.

PASTINACA *ſativa*, parſnep. By ſeed annually in ſpring, for winter uſe.

PHASEOLUS *vulgaris*, common kidney-bean, which may be divided into two claſſes, —dwarfs and runners.

——— *Dwarfs*, are—early white—early yellow—liver-coloured—ſpeckled dwarf—Canterbury white dwarfs—Batterſea white dwarf—large white dwarf——cream-coloured dwarf—black dwarf—ſparrow-egg dwarf—amber-ſpeckled dwarf. All by ſeed annually at different times from April till Auguſt.

——— *Running kinds*—ſcarlet runner, and white variety—large Dutch runner—Batterſea white runner—Negro runner—variable runner. By ſeed like the former.

PISUM, the pea—Charlton pea—golden Charlton—earlieſt golden Charlton——long Reading hotſpur—Spaniſh morotto——green nonpareil—early dwarf marrowfat——large marrowfat—green rouncival, or union——white rouncival—Ledman's dwarf pea—ſmall ſugar-pea—large ſugar-pea—cluſter-pea——crown-pea—egg-pea——ſickle-pea. All by ſeed annually, at different times from October till June.

PORTULACA *oleracea*, purſlane——green purſlane—golden purſlane. Both by ſeed, in April and May.

POTERIUM, *ſanguiſorba*, burnet. By ſeed and parting the roots.

RAPHANUS *ſativus*, the radiſh——ſhort-topped early radiſh—long-topped radiſh——deep-red radiſh—pale-red, tranſparent, mild radiſh—ſalmon-coloured radiſh—ſmall white turnep-rooted radiſh—large, white, turnep-rooted, Spaniſh radiſh——large, black, turnep-rooted, Spaniſh radiſh. All the ſorts by ſeed at different times from Chriſtmas till July or Auguſt; but the latter for winter uſe.

ROSEMARINUS, roſemary, ſome varieties. By layers, ſlips, and cuttings, in ſpring.

RUMEX *acetoſa*, ſorrel——common long-leaved ſorrel—round-leaved French ſorrel—barren ſorrel. By parting the roots, and the firſt ſort alſo plentifully by ſeed.

RUTA, *graveolens*, rue; ſeveral varieties. All by ſlips and cuttings.

SALVIA, ſage, clary, &c. The ſorts are:

SALVIA *officinalis*, common ſage——red ſage——broad-leaved green ſage——narrow-leaved green ſage—broad leaved hoary ſage—ſage of virtue—wormwood ſage, &c. By ſlips in April and May.

SALVIA *ſclarea*, clary. By ſeed annually.

SATU-

SATUREJA, ſavory—winter perennial ſavory—ſummer annual ſavory. Both by ſeed, and the former alſo by ſlips.

SCANDEX *cerefolium*, chervil. By ſeed annually in Auguſt, for winter and ſpring uſe.

SCORZONERA, *ſcorzonera*, an eatable root, raiſed from ſeed in ſpring.

SINAPIS, muſtard—white muſtard—black muſtard—field, or wild muſtard: the former to uſe young in ſallad, and the two laſt for their ſeeds, to make muſtard. All by ſeed in ſpring, or if for ſallads, at any time of the year.

SIUM *ſiſarum*, ſkirret; an eatable root. By off-ſets commonly, of the root, alſo by ſeed.

SOLANUM, night-ſhade, furniſhes the potatoe and tomatoe. The ſorts are:

SOLANUM *Tuberoſum*, tuberous-rooted ſolanum, or potatoe—common round red potatoe—early round red—oblong red—deep-red—pale-red—rough red—white kidney-ſhaped—red-ended white kidney—white round—white cluſter—prolific American. By pieces of the roots, or the roots whole, in ſpring.

SOLANUM *lycoperſicum*, tomatoe, or love-apple; ſome varieties. All by ſeed annually.

SPINACIA, ſpinach—round thick-leaved, or ſmooth-ſeeded—triangular-leaved, or prickly-ſeeded; the former for ſpring and ſummer crops, the latter to ſtand the winter. Both by ſeed annually in ſpring, ſummer and autumn, for uſe moſt part of the year.

TANACETUM *vulgare*, common tanſey. By parting the roots in ſpring or autumn.

THYMUS *vulgaris*, common thyme; having ſome varieties. By ſeeds in March and April; alſo by ſlips of the root and branches, and by cuttings; but ſeed is the only way to raiſe a quantity of the common ſort; and the other methods to continue the varieties.

TRAGOPOGON *porrifolium*, ſalſafy; an eſculent root. By ſeeds annually in ſpring.

TROPÆOLIUM, Indian creſs, or naſturtium—naſturtium minus—naſturtium majus; their flowers for garniſh and ſallads, and their ſeeds to pickle. Raiſed annually from ſeeds in ſpring.

VALERIANA *locuſta*, corn-ſallad, or lambs-lettuce. By ſeed in ſpring and autumn.

VICIA *faba*, the bean—early Mazagan—early Liſbon—long-pod—Turkey long-pod toker bean—Sandwich bean—Windſor bean—white-bloſſomed—red-bloſſomed—Spaniſh bean—nonpareil bean—dwarf ſan bean, very low. All of them by ſeed annually, at different times from October until June.

For a particular deſcription, and method of culture of all theſe Kitchen garden plants, ſee each under its reſpective genus as above.

---

# L.

LABIATUS *Flos*, a lip-flower; a monopetalous irregular flower, divided into two principal diviſions, reſembling two lips.

Labiated, or Lip-flowers, make part of the ringent, or grinning tribe; ſee COROLLA RINGENS; and of which are moſt of the verticillate plants, as baum, mint, hyſſop, ſage, clary, marjoram, ſavory, lavender, thyme, and many others, moſt of which produce their flowers in a verticillus, or whirls round the ſtalks and branches. See VERTICILLUS.

LABYRINTH, a ſort of wilderneſs-plantation, abounding with hedges and walks, diſtributed into many winding and intricate turnings, leading to one common centre, extremely difficult to find out; deſigned in large gardens by way of amuſement.

A Labyrinth is formed with hedges commonly in double rows, leading in various intricate turnings, backward and forward, with

with intervening plantations and gravel walks alternately between hedge and hedge; and the great aim is to have the walk contrived in ſo many mazy, intricate windings to and fro, that a perſon may have much labour and difficulty to find out the centre of the Labyrinth, by meeting with as many ſtops and diſappointments as poſſible; for he muſt not croſs or break through the hedges; ſo that in a well-contrived Labyrinth a ſtranger will often entirely loſe himſelf, ſo as neither to find his way to the centre, nor out again the way he came in.

Theſe Labyrinths are rarely introduced now in our modern garden deſigns; and ſcarce to be ſeen, but in ſome old noble gardens.

As to the plan of them, it is impoſſible to expreſs it with any propriety by words, no farther than the above hints; but there are different plans, and the contrivance of them muſt depend on the ingenuity of the deſigner.

But as to their hedges, walks, and trees; the hedges are uſually of hornbeam, but may alſo be of beech and elm, or any other that can be kept neat by clipping, ſee HEDGES. The walks ſhould be five feet wide at leaſt, laid with gravel and neatly rolled; and the trees and ſhrubs to form a thicket of wood between the hedges may be any of the hardy kins of the deciduous tribe interſperſed, if you pleaſe, with ſome ever-greens; and in the middle of the Labyrinth ſhould be a ſpacious open for the centre.

Sometimes ſmall Labyrinths are formed with box-edgings, and borders for plants, and alleys for walking, in imitation of the large ones, and which have a good effect in ſmall gardens.

LACTESCENTIA, milkineſs; Lacteſcent plants, are ſuch as abound with a milky juice, ſuch as lettuce *(lactuca)*, dandelion, and many others.

The colour of the juice in queſtion, is white in moſt plants, though in ſome it is yellow, in others red; moſt Lacteſcent plants are ſaid to be poiſonous, except thoſe with compound flowers, which are of an innocent quality.

Among the poiſonous ſorts may be reckoned, *euphorbia*, ſumach, celandine, caſſada, cardinal-flower, ſwallow-wort, apocynum, &c.

Among thoſe innocent in their quality, are all the ſorts of the *lactuca ſativa*, or cultivated lettuce, ſalſafy, dandelion, &c.

LACTUCA, Lettuce.

One ſpecies only of this genus furniſhes all our valuable varieties of Lettuce; all of which are herbaceous annuals of great eſtimation for ſallads, and many culinary purpoſes; are in greateſt perfection in ſummer, but may be continued moſt part of the year; though being rather impatient of ſevere froſt, cannot be obtained in any tolerable perfection in winter, unleſs planted under ſhelter of frames, &c. their cabbaged inner leaves are the uſeful parts, which having obtained perfection, the plants ſoon after ſhoot up tall branchy ſtalks, terminated by compound yellowiſh flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis*.

*Characters.*] CALIX, a compound flower, having a ſcaly imbricated general cup. COROLLA, many tongue-ſhaped hermaphrodite flowers, placed imbricatum. STAMINA, five ſhort filaments, and cylindric antheræ. PISTILLUM, an oval germen, ſlender ſtyle, and two reflexed ſtigmas. PERICARPIUM, none. SEMINA, a ſingle compreſſed ſeed to each floret, crowned with a ſimple down, ſitting on the receptacle.

The cultivated ſpecies of Lettuce is;

LACTUCA *Sativa*.

*Cultivated Lactuca, or Common Lettuce.*] Hath a long taper root, crowned by many large roundiſh, or oblong oval, cloſe-ſitting leaves, in ſome ſpreading, others erect, the inner ones contracting gradually, and form a cloſe, firm, cabbaged head; and from the centre of which riſes the flower-ſtalk, branching two or three feet high, having all the branches terminated by ſmall compound yellow flowers, ſucceeded by ſmall, flat, downy ſeeds, in autumn.

The varieties of this ſpecies are very numerous, but the real valuable ſorts now commonly cultivated, do not amount to above ſix or ſeven; and it is better to cultivate only a few of the known good kinds, than to confuſe the ground with a great multiplicity of ſorts, unleſs required merely for variety. We will, however, exhibit a liſt of the principal, and leſs material varieties ſeparate.

*Principal Varieties.*] Hardy green cabbage-lettuce—white cabbage-lettuce—great, admirable, white cabbage lettuce, very large—brown Dutch cabbage-lettuce—green coſs-lettuce—white coſs-lettuce—brown Sileſia-lettuce. All the cabbage kinds are of ſpreading

ing growth, but cabbage firmly; and the other ſorts grow upright, and alſo cabbage very large.

All theſe ſeven varieties are excellent Lettuces for general culture, though the green, and the white coſs kinds, are in moſt eſteem for the general ſummer crops; and the green coſs rather excells all the coſs kinds for ſize and goodneſs; but as all the above varieties both of the cabbage and coſs kinds cabbage exceeding fine, a few of each is worth culture in every garden for general uſe; but rather moſt of the coſs kinds for ſummer, and moſt of the others for autumn and winter; and the hardy cabbage, brown Dutch, and green coſs, are proper alſo to ſtand the winter for ſpring ſervice; but if thought proper ſome of each ſort may be uſedfor either or all of theſe ſeaſons, except the great admirable Cabbage-lettuce, which being rather tender, at leaſt, does not ſucceed for early nor late crops, ſo ſhould be ſowed principally in April and May, and will cabbage remarkably fine in July and Auguſt. All the other varieties, however, may be ſowed any time in ſpring, ſummer, and autumn. See their *Propagation, &c.*

*Leſs material Varieties.*] Small, early, green ball-cabbage Lettuce—white ball cabbage Lettuce: both theſe are varieties of the common green and white Cabbage-lettuce—green capuchin Lettuce—red capuchin Lettuce—imperial Lettuce, large—ſpotted Coſs-lettuce——black Coſs-lettuce, large and ſomewhat ſpreading. All theſe varieties cabbage to firm heads; though inferior to the former claſs of varieties for general uſe; but their culture is all the ſame as the others; and, if required for variety, may be raiſed abundantly by ſeed in ſpring, ſummer, and autumn. See their *Propagation.*

All the above varieties of Lettuce in each claſs, are tolerable permanent, eſpecially if care is taken to ſave ſeeds only of the very beſt of each ſort; and the different ſorts always as far diſtant from each other as poſſible, that their *farina* may not mix and cauſe a degeneracy, for it is by not ſtrictly obſerving this that ſo many are diſappointed in their crops, by having Lettuce not of the approved ſorts, and thoſe often ſmall and inſignificant, running to ſeed before they have half cabbaged; therefore great regard ſhould be had in the choice of the plants for ſeed, according to the above hints, and as directed under the article of *ſaving the ſeed*, by which you may depend on continuing plants of the approved kinds in the utmoſt perfection.

The plants in general may be conſidered both as annuals and biennials, for thoſe ſowed in ſpring and ſummer, attain perfection, run up to ſeed, and periſh the ſame year; but the autumn ſowings will ſtand all winter until ſpring following, when they attain perfection, then ſhoot up for ſeed, and periſh root and all.

All the ſorts are hardy enough to grow in any common ſoil of a kitchen-garden, in a free ſituation open to the ſun and air; but being rather impatient of ſevere froſt and wet ſoils in winter, ſhould have a dry warm ſituation in that ſeaſon, and ſome ſhould be kept under frames and other ſhelters, the more effectually to preſerve, and forward them for uſe during that ſeaſon and ſpring-time.

Their uſe is principally for ſallads, when arrived to full growth and cabbaged, that the inner leaves become blanched, criſp, and ſweet, otherwiſe would eat tough and bitter taſted; but ſometimes alſo the young open plants of the cabbage Lettuces are uſed in ſpring, till the other general crops arrive to perfection: the white cabbage being the moſt eligible for this uſe, as they eat ſweeter than any other ſorts while young and open. Quite young open Lettuces are alſo often uſed as ſmall ſallad herbs, ſowing them thick in rows, like creſſes, &c. and gather them for uſe in the ſame manner as for thoſe plants; but this mode of culture is more particularly practiſed in winter and ſpring. Lettuces, however, in general eat no way ſo criſp, ſweet, and palatable, as when fully cabbaged; and are themſelves ſufficient for a ſallad, if thought proper, without the addition of other herbs. The fully cabbaged Lettuces are alſo excellent for ſtewing and for ſoups, and other culinary uſes.

The ſeaſon of Lettuces may be continued moſt part of the year, by different ſowings; but their principal ſeaſon of greateſt perfection is June, July, and Auguſt, in which months the ſpring-ſowed plants arrive to a large ſize, and finely cabbaged. However, by ſeveral different ſowings in ſpring, ſummer, and autumn, they may be had cabbaged leſs or more the year round: the ſpring ſowings furniſh the main ſummer crops, the ſummer ſowing for autumn uſe; and the late autumnal ſowing, ſtand the winter, and ſome of which will be fit for uſe in that ſeaſon, and if occaſionally ſheltered, ſome will be tolerably,

tolerably cabbaged; and others arrive to perfection in ſpring and beginning of ſummer, before the ſpring-ſowed plants come in.

*Propagation, and Seaſon for ſowing all the Sorts.*

The propagation of all the ſorts of Lettuce is by ſeed annually, and that to continue a regular ſucceſſion of them for uſe at all times of the year, ſix or eight different ſowings, at leaſt, is neceſſary; but the principal ſowing-ſeaſon for the main crops, is ſpring, in February, March, April, and May; which will furniſh a conſtant ſupply of good Lettuces from May till Auguſt or September; and by latter-ſowings they are continued longer accordingly: as the plants, however, of all the ſowings, after having attained their proper ſize, and fully cabbaged, they ſoon after run up to ſeed, ſo that to inſure a continued ſucceſſion as long as poſſible, a ſowing may be performed every three weeks or month, from January until September or October. The ſpring and ſummer-ſowings furniſh Lettuce for uſe from April or May until November; and the autumn-ſowings in Auguſt, September, and October, come in for uſe late in autumn, and in winter; and for early ſpring Lettuces, as before obſerved, in warm borders, under walls, and in frames, and other ſhelter; obſerving that all the ſorts ſucceed either by remaining where ſowed, thinning them to proper diſtances; or by tranſplantation, placing them a foot at leaſt aſunder; but it is proper always to tranſplant a principal quantity of each ſowing, both to thin the ſtanding plants properly, and to obtain a longer ſucceſſion of each crop, for the tranſplanted Lettuces will ſucceed the ſtanding plants for uſe, and often grow larger, and generally remain longer in perfection before they run.

The main crops of Lettuces ſhould generally be ſowed diſtinct from other crops, and each different variety ſeparate; they, however, are very commonly ſowed thin among other ſmall crops, to ſave ground; ſome of the plants deſigned for tranſplantation into other places, and ſome to remain at good diſtances for cabbaging; ſo are frequently ſowed among early radiſhes and ſpinach, alſo among onions, leeks, carrots, parſneps, &c. particularly the upright ſorts of Coſs-lettuces; any of the ſorts are likewiſe often ſowed thin among winter ſpinach, but chiefly the common green cabbage, and brown Dutch kinds; but in ſowing any ſorts of Lettuces among any of theſe crops, a thin ſprinkling ſhould only be admitted; but when there is plenty of ground, I ſhould be for ſowing the main crops principally diſtinct by themſelves, and the plants thinned out, leaving ſome to remain for cabbaging where ſowed, and tranſplant the reſt into another ſpot of ground as hereafter directed.

Obſerve, as before noticed, that when intended to have early young open Lettuces for ſpring uſe, the white cabbage kinds are the proper ſorts to ſow for that purpoſe, and may begin to thin the young plants for uſe, when their leaves are an inch or two broad, which may be continued as they are wanted, leaving ſome at regular diſtances to arrive at full growth.

But for full-grown Lettuces, it is proper to ſow the different ſorts both of the principal cabbage and coſs kinds at the ſame time in ſeparate ſpots of ground, whereby you will have a regular ſupply of each ſort, only obſerving at each ſowing to ſow moſt of thoſe ſorts that are in the greateſt requeſt either for family uſe or market; remarking the ſorts, as before directed, that are the moſt proper for uſe at the different ſeaſons of the year, and the different times of ſowing as above mentioned.

The early ſowings of all the ſorts ſhould be performed on a warm border, or ſome dry ſheltered ſituation, to have the crops as forward as poſſible; and if required to have a few early Lettuces as forward as can be, they may be greatly forwarded by ſowing in a ſlender hot-bed in January or February; particularly the white and green Coſs-lettuce, and if the young plants of an inch or two high are pricked out into another ſlight hot-bed, it will ſtill bring them more forward; and after having a month's growth ſome may be thinned out in mild weather, and planted a foot diſtance in the open ground; but in default of hot-beds, a few may be ſowed in frames, or under hand-glaſſes in a bed or border of natural earth, to have ſhelter on nights and cold weather, which may bring them a little forwarder than thoſe fully expoſed. The ſowing, however, in a hot-bed, or under frames, &c. is more particularly neceſſary after a ſevere winter, when the autumn-ſowed crops of Lettuces deſigned for ſpring uſe are cut off; but in mild winters, when a plentiful ſupply of the autumn Lettuces have ſurvived the winter, there will be little

little occaſion for any other precaution than to ſow the earlieſt ſpring-ſowings on warm borders, &c. as aforeſaid.

But the general ſpring and ſummer-ſowings for the main crops, for ſummer and autumn uſe, ſhould be performed principally in any open ſituation, in the quarters, or large open borders, the more diſtant from ſpreading trees and buſhes the better; the ſame ſhould alſo be obſerved in the tranſplanted Lettuces, for when under, or too near ſhady places, they always draw up weak, never cabbage large, and ſoon fly up to ſeed; whereas thoſe in a free expoſure are of robuſt growth, and cabbage large and firm.

The ſowings of all the ſorts at every ſeaſon is performed principally by broad-caſt on the ſurface; obſerving, as the ſeeds are ſmall and thin, particular care is requiſite in ſowing, to ſpread them regular, and not too thick, and rake them in with an even hand; or thoſe ſowed in hot-beds under frames, may, inſtead of raking-in, have earth ſifted over them near a quarter of an inch deep; and in about from eight or ten to fifteen or twenty days after ſowing, in either method, the plants will appear, which are to be managed according to the following directions.

*Their general Culture.*

When the plants of each ſowing come up, their principal culture is to keep them clean from weeds, thin them where too cloſe, and tranſplant ſome of each ſowing; but as to the earlieſt ſowed plants, which come up early in ſpring, if attacked while very young with ſevere froſt, thoſe in borders may be defended with a light covering of dry long litter occaſionally; and thoſe in hot-beds, or under frames, &c. in the full ground, by covering with the glaſſes. The weeding and thining the different crops of theſe plants may be performed either by hand or hoe; obſerving, if deſigned to have the principal crops of plants to remain where ſowed to attain perfection, and that they form a crop of themſelves, hoeing will be the moſt beneficial, both to deſtroy weeds and thin the plants to proper diſtances, leaving them fifteen or eighteen inches aſunder, unleſs it is neceſſary to thin them by degrees, either by occaſional tranſplantings, or by drawing out young plants for uſe, as they may be wanted; but when any conſiderable quantity of the plants are deſigned for tranſplantation, which is adviſeable in every crop, the weeding and thinning ſhould principally be performed by hand; ſo thinning out the largeſt plants occaſionally for tranſplanting, leaving enough of the others at regular diſtances, as above, for a crop to arrive to full ſize. It is, however, always proper to tranſplant ſome of each ſowing, by which you will have the longer ſucceſſion of good plants.

When deſigned to tranſplant any ſort of Lettuce, it ſhould be done when the plants are about three or four inches high, not more, for when larger they are apt to flag greatly, and do not root ſo freely as younger plants: moiſt weather will be particularly neceſſary for this work. Take up the plants with care, ſo as to preſerve as much root as poſſible; and proceed to plant them by line and dibble, in rows, a foot at leaſt aſunder, but if fifteen or eighteen inches diſtant the better, eſpecially for the larger kinds, ſuch as the grand admirable cabbage Lettuce, and the white and green coſs, allowing the ſame diſtance between the plants in each row; and if ſet in the quincunx order, the plants will have ſtill more room to grow. As ſoon as planted, give water, which ſhould be repeated, if dry weather, ſeveral times for the firſt week or ten days, till the plants have taken freſh root, and beginning to advance in growth.

Thus continue planting out a quantity every three weeks, from March, April, or May, until September or October, whereby you will have a daily ſupply of good well-cabbaged Lettuces eight or nine months in the year; and thoſe planted out late, will ſtand the winter, and cabbage early in ſpring.

If the ſummer tranſplantings are planted in ſhallow drills, it will be ſome advantage in facilitating the freſh-rooting of the plants, as the drills will confine the water given principally about the plants, and alſo retain the moiſture longer than the level ſurface. See DRILLS.

Tying up Lettuces to forward their cabbaging, and to whiten and render them criſp, is often practiſed to the early ſpring and ſummer crops, particularly coſs Lettuces. When the plants are well advanced in growth, and beginning naturally to form their inner leaves for cabbaging, tie all their leaves up cloſe together with a piece of baſs, a little above the middle of the plant, not too ſtrait,

but ſo as the whole plant may have room to grow; beſides, if tied too cloſe, they are apt to rot in the heart: this work of tying, however, is only neceſſary for ſome of the earlieſt plants of the forward crops, the ſucceeding ones will cabbage faſt enough without that aid; only obſerving, if any ſorts ſhould be backward in cabbaging, as is often the caſe with the black coſs Lettuce, they may always be facilitated therein by the above practice.

*Winter and early Spring Crops.*

Winter Lettuces, both for winter uſe, and to ſtand the winter in warm borders and in frames, &c. for ſpring ſervice, are obtained by two or three different ſowings in autumn, from the middle or latter end of Auguſt until the end of September or October.

That is, to have Lettuces ſtand for uſe all winter, and early in ſpring, ſow ſome hardy green and white cabbage Lettuce, brown Dutch, and green coſs, about the middle of Auguſt, and beginning of September, in any open ſituation, and the plants will come up in a week or ten days; about the end of September, and in October, plant out a parcel of the beſt plants of each ſowing, in a warm dry ſituation, ſix or eight inches aſunder; and at each planting, plant alſo ſome under frames at the ſame diſtance; to be covered with glaſſes every cold night, and all bad weather; or for want of frames, plant them under hand-glaſſes, or in a bed arched over with hoops or rods, to be covered with mats in winter froſts; but if you uſe frames, chuſe them as ſhallow as poſſible, and ſink the back part in the ground, ſo as to be only equal in height with the front, that the ſurface of the bed and plants may be all an equal diſtance from the glaſſes, if not more, at firſt, than ſix or eight inches, the better, as it will prevent their drawing up weak and open, which is the caſe when in very deep frames, but in ſhallow ones, they will be more robuſt and cloſe, and being nearer the glaſſes, they will be forwarded more in growth during winter. Under either of the above ſhelters, let the plants enjoy the free air in mild dry weather; but cover them every cold night, with the proper covers, eſpecially after October, alſo in all very cold, and in very wet weather, day or night, particularly thoſe in frames and under glaſſes; and as to thoſe in hand-glaſſes, they may have the glaſſes almoſt conſtantly over them in winter, tilting up one ſide in mild weather, and only ſet them entirely off in fine mild dry days; but in ſharp froſty weather keep thoſe under every kind of ſhelter quite cloſe; allowing alſo additional covering of mats or litter, when the froſt is very intenſe; thoſe in the borders may alſo be defended by ſome light litter; but at no time ſuffer the covering to remain longer on any of the crops than the bad weather continues, but indulge them with free air every mild day. By the above practice you may have Lettuces for uſe moſt part of winter, and early ſpring, particularly the cabbage Lettuces: thoſe planted out firſt will be fit for uſe in November and December, and the ſecond planting will come in towards Chriſtmas, and being ſheltered by the glaſſes, will continue coming in for winter and ſpring uſe till ſucceeded by the other latter autumn ſowings; obſerving according as any are gathered out of the frames or glaſſes, ſome may be removed from the borders to fill up the vacancy, whereby the glaſſes may be conſtantly employed during the winter.

Sometimes for Lettuces intended to be planted in frames late in autumn for winter uſe, a moderate hot-bed is made for their reception, in order that they may be well forwarded in the beginning of winter, and if the heat is continued moderately by aid of linings, allowing plenty of air all mild weather, the plants will be very fine by Chriſtmas, or thereabout.

*Winter-ſtanding Spring Crops.*

But to have Lettuces principally for ſpring uſe, ſome ſeed ſhould be ſowed towards the middle and latter end of Auguſt to ſtand the winter, ſome where ſowed, others to be tranſplanted into warm borders, to ſtand without any other ſhelter than that of the walls or other fences; and another ſowing ſhould be performed about the middle of September, to raiſe plants for pricking under frames to have ſhelter of the glaſſes all winter, to be as a reſerve in caſe thoſe in the borders are deſtroyed; if both ſtand, one will ſucceed the other.

In the former caſe, a quantity of the plants, when two or three inches high, in October, or early in November, ſhould be planted out into a warm dry ſituation, in rows ſouth and north, ſix inches aſunder, and here let them remain to take their chance all winter: out of the whole many of them will probably eſcape the froſt; but in very ſevere weather they

they may be protected by a light covering of dry long litter, which remove away again in due time when the froſt breaks. In March or April, if they remain too thick, ſome ſhould be thinned out and planted in another place, in rows, twelve or fifteen inches aſunder; theſe crops, thus wintered in the open ground, will come in for uſe in April and May, to ſucceed thoſe others ſowed in autumn, and ſheltered occaſionally all winter, and will remain good till the ſpring ſown plants come in.

In the latter caſe, i. e. thoſe ſowed in September, to be wintered in frames, ſhould be planted therein about the latter end of October, or beginning of November, planting them in rows from the back to the front of the frame, three inches diſtance; cloſe the earth well about each plant, finiſh with a moderate watering all over the plants, and put on the glaſſes to promote their more ſpeedy rooting anew, ſhoving the lights, however, two or three inches down, to give vent to the moiſt vapour ariſing from the mould; but when the plants have taken freſh root, and ſet to growing, admit the full air every mild dry day, by taking the glaſſes entirely off, which muſt be continued throughout the winter ſeaſon, in all dry mild weather, but put them on every night, in cold or very wet weather eſpecially; even alſo adays when great rains prevail; and in froſty weather keep the glaſſes always on, except in the middle of ſunny days, but when the froſt is very ſevere, keep them cloſe night and day, uſing alſo other covering of mats or long litter over the glaſſes, and around the ſides of the frame. During the winter, keep all decayed leaves picked off; and as the ſpring and warm weather advances, let them have the benefit of warm ſhowers.

Thoſe thus wintered may be effectually preſerved, if thoſe in the openground ſhould be deſtroyed by the froſt or exceſſive moiſture.

In March tranſplant ſome of them into the open ground, in rows, a foot at leaſt aſunder, water them moderately till freſh-rooted; obſerving to leave a crop remaining in the frames or winter-bed, a foot alſo apart, to ſtand to cabbage; which will arrive to perfection ſome conſiderable time before the tranſplanted ones, and thoſe that have been fully expoſed all winter.

For want of frames for the above purpoſe, a quantity of the plants may be pricked out under hand or bell-glaſſes in autumn, to ſtand the winter, either by themſelves for a full crop, or may plant ſome under the hand or bell-glaſſes, that are placed over early cauliflowers, as practiſed by the London gardeners, planting them round juſt within the glaſſes; managing them as directed for the frames; and early cauliflowers under hand or bell-glaſſes; or for want either of a ſufficiency of frames or hand-glaſſes, plant out a quantity in autumn, in four-feet wide beds, in a warm ſituation, and arch them over with hoops or rods, to cover with mats and litter in bad weather, as aforeſaid: they will here have a better chance of ſurviving the winter than thoſe fully expoſed; and in ſpring tranſplant a quantity, by way of thinning, into other beds, as as above directed.

Lettuces are ſold in the markets by the ſcore, which in London, thoſe that come in early, often fetch from half a crown to five ſhillings, but fall gradually in price, as the ſeaſon advances, to ſix pence or three pence per ſcore, two and twenty to each ſcore; though the fine large coſs Lettuce ſeldom much leſs than a ſhilling per ſcore of plants.

*Saving Seed of all the Sorts.*

To ſave Lettuce ſeed. Let it be remarked, that ſome of the early plants of all the ſorts ſhould principally be choſen for ſeed plants, for thoſe of the latter crops rarely run ſoon enough to ripen ſeeds perfectly before they are attacked by the autumnal rains and cold, which greatly retards the ripening of all ſorts of Lettuce ſeed; therefore, ſelect either ſome of the the winter-ſtanding plants, or ſome of the forwardeſt plants of the February or March ſowing; and the largeſt and beſt cabbaged of each reſpective kind, mark this, if you would continue your Lettuce fine; likewiſe it is of importance, as before hinted, to have the different varieties intended for ſeed, at ſome diſtance from each other, becauſe, if too near, the *ſemen maſculinum* of the different ſorts may mix and fecundate one another, and thereby a degeneracy or mongrel breed will be the conſequence, and the true ſorts would in time be loſt; and it is by not obſerving the above particulars by thoſe who ſave large quantities of ſeed for ſale, that ſo many baſtard bad ſorts of Lettuces are diſperſed about the country.

The ſeed ripens in Auguſt and September, but that of each plant rarely ripen all equally together, ſo that according as it ar-

rives to perfection, the reſpective branches ſhould be cut off in dry days, and ſpread upon a cloth, or tied in ſmall bunches, and hung up acroſs lines in a dry airy loft, for a week or two to dry and harden; then beat them out, and clean them from the down and other rubbiſh, and expoſe them upon cloths a few days to dry for keeping; then put them up in bags for uſe, and hang them in a dry room.

In many places where the farming gardeners cultivate great quantities of theſe plants in fields for ſeed, to ſerve the dealers, they pay but little regard to the goodneſs of the plants, but when they are a few inches high, hoe them out to about a foot diſtance, leaving them good, bad, and indifferent to ſtand to ſeed, which is very wrong, as many perſons are thereby diſappointed of their crops, by having moſt of the plants run before they are half-grown: the cultivators for ſeed ſhould, therefore, after the firſt hoeing, look over the plants from time to time, and clear out all thoſe that run up for ſeed before they cabbage, and reſerve only thoſe that are largeſt and beſt cabbaged.

All ſorts of Lettuce produce the greateſt quantities of ſeed in dry warm ſeaſons, and in wet cold autumns they ripen ſeed very ſparingly, and that late, and often very indifferent in reſpect to goodneſs for ſowing.

Lettuce ſeed is ſold in the ſhops by retail, at from ſix pence to a ſhilling the ounce; and may be had in any quantity from a quarter of an ounce to a pound, as ſhall be convenient, according to the extent of the garden, or demands of a family for the plants.

LANTANA, American Viburnum.

This genus conſiſts principally of ſhrubby exotics of Africa and America, for the greenhouſe and ſtove; growing a yard or two high, adorned with oval, oblong, and roundiſh ſimple leaves, and monopetalous tubular four-parted flowers.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX, is monophyllous, ſhort, tubular, and four-parted. COROLLA, is monopetalous, with a cylindric tube, ſpreading at top, and divided into four obtuſe ſegments. STAMINA, two long and two ſhort filaments, and roundiſh antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and crooked ſtigma. PERICARPIUM, a roundiſh drupaceous unilocular fruit, containing a roundiſh bilocular nut.

There are about four or five ſpecies retained in the Engliſh gardens, two for the greenhouſe, the others for the ſtove.

*Green-houſe Kinds.*

[1]LANTANA *Africana.*

*African Ilex-leaved Lantana.*] Hath a ſhrubby ſtalk, branching irregularly five or ſix feet high; oval, pointed, ſerrated, cloſe-ſitting, alternate leaves, and white flowers, ſingly from the ſides of the branches.

[2]LANTANA *Salvifolia.*

*Sage-leaved Lantana.*] Hath a ſhrubby ſtalk, branching five or ſix feet high; oblong, pointed, rough, cloſe-ſitting, oppoſite leaves, four or five inches long; and flowers in cluſters from the upper parts of the branches.

*Hot-houſe Kinds.*

[3]LANTANA *Trifolia.*

*Trifoliate Lantana.*] Hath a ſhrubby, woolly-barked ſtalk, branching about a yard high; oblong, indented, rough leaves, placed ſome by threes, others oppoſite; and purple flowers in oblong roundiſh ſpikes from the ends of the branches.

[4]LANTANA *involucrata.*

*Involucrum-headed Lantana.*] Hath a ſhrubby ſtalk, branching four or five feet high; roundiſh, indented, rough leaves, by pairs oppoſite; and from the ends of the branches, umbellate heads of purple flowers, attended by many ſmall leaves like an involucrum.

[5]LANTANA, *Camara.*

*Camara, or Leafleſs-headed Lantana.*] Hath a ſhrubby ſtalk branching five, ſix, or eight feet high, in different varieties; oblong, indented, rough oppoſite leaves, two or three inches long; and from the ſides and ends of the branches umbellate heads of yellow, purple, or red flowers in the varieties, unattended by leaves.

*Variety.*] Nettle-leaved leafleſs-headed Lantana.

[6]LANTANA, *Aculeata.*

*Prickly Lantana.*] Hath a ſhrubby ſtalk, branching three or four feet high, the branches angulated and armed with crooked ſpines; oval, ſpear-ſhaped, hairy, oppoſite leaves; and from the ſides and ends of the branches umbellated heads of ſcarlet flowers, having the centre ones yellow or orange-coloured.

All theſe ſpecies have durable woody ſtalks and branches, retaining their leaves moſtly all the

the year, moſt of which are very rough; the flowers of all the ſorts are of one petal with a cylindric tube, divided above into four parts, (ſee the *Characters*) and appear from June or July until winter; ſometimes ſucceeded by largiſh berry-like fruit, ripening here in warm autumns.

Theſe plants are all of foreign growth; the two firſt of Africa, and the others of the warm parts of America; and all of them require ſhelter here in cold weather, the two former of the green-houſe, and the other four of the ſtove; ſo muſt be alaways kept in pots of light rich earth, and placed among the plants of thoſe two departments; the two green-houſe kinds may be placed in the open air all the ſummer; but the others only in the hotteſt months of that ſeaſon.

Their propagation is by ſeeds and cuttings, in hot-beds.

By Seed.—Sow it in pots of light earth, and plunge them in a bark hot-bed, and when the young plants are ſome inches high, prick them in ſeparate ſmall pots, and plunged alſo in the bark-bed; and inure the green-houſe kinds to the open air in ſummer, the others but little the firſt ſeaſon.

By Cuttings.——Cuttings of the young branches may be planted in pots in ſpring and ſummer, and plunged in a hot-bed, they will readily take root, and ſhoot at top the ſame year.

LATHYRUS, Chickling Vetch, compriſing the everlaſting and ſweet-pea, &c.

The plants are herbaceous climbers; of which there are three noted ſpecies of the flowery tribe, proper for the decoration of the pleaſure-garden; a perennial, and two annuals; all of them riſing with cirrhous-climbing ſtalks, mounting upon ſupport ſeveral feet high, adorned with diphyllous cirrhous leaves, and papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, bell-ſhaped, and five-parted at top. COROLLA, is papilionaceous, having a heart-ſhaped ſtandard, two oblong, lunulated blunt wings, and a half-round keel. STAMINA, ten diadelphous filaments, and roundiſh antheræ. PISTILLUM, an oblong narrow compreſſed germen, flat acuminated ſtyle, and hairy ſtigma. PERICARPIUM, a long compreſſed, acuminated, bivalvular pod, filled with roundiſh ſeeds, like garden peas.

There are many ſpecies of this genus, but not more than three that are commonly cultivated; all of which are for ornament.

[1]LATHYRUS *Latifolius.*

*Broad-leaved perennial Lathyrus, commonly called Everlaſting Pea.*] Hath thick, fibrey, perennial roots; climbing, thick, branching, annual ſtalks, having membranaceous wings between the joints, riſing upon ſupport by their cirrhi ſix or eight feet high; diphyllous leaves, of two ſpear-ſhaped lobes, terminated by claſpers; and numerous large red or purple flowers, on long foot-ſtalks, appearing plentifully from June till October, ſucceeded by abundance of ſeed.

[2]LATHYRUS *Odorata.*

*Odoriferous annual Lathyrus, commonly called Sweet-ſcented Pea.*] Hath a fibrey annual root; a climbing ſtalk, riſing upon ſupport, by its claſpers, three or four feet high; diphyllous leaves, of two oval lobes, terminated by climbing tendrils; and flowers by twos on long flower-ſtalks; of different colours in the varieties.

*Varieties of this are*] Purple-flowered ſweet-pea—white-flowered ſweet pea—variegated, or painted-lady ſweet-ſcented-pea. All of which flower in ſummer, from May or June until October, by different ſowings.

[3]LATHYRUS *Tangitanus.*

*Tangier annual Lathyrus, commonly called Tangier Pea.*] Hath a fibrey annual root; climbing ſtalk, riſing upon ſupport four or five feet high; diphyllous leaves, of two ſpear-ſhaped alternate lobes, terminated by tendrils; and from the joints of the ſtalk, large reddiſh flowers by twos, on long foot-ſtalks.

All theſe ſpecies of Lathyrus are herbaceous, and of hardy growth, their ſtalks long, ſlender, and furniſhed with cirrhi, or claſpers for the purpoſe of climbing and ſupporting themſelves; the firſt ſort, *Lathyrus Latifolius*, is perennial, or everlaſting in root, but annual in ſtalk; and the other two are annual in ſtalk and root, riſing from ſeed in ſpring, and wholly periſh in autumn. They all merit culture as flowery plants, but the perennial ſort is the moſt valuable, both for its durability in root, and long continuance in bloom; the two annual ſorts, however, flower very ornamentally, and by three or four different ſowings, may be made to flower all ſummer and autumn.

The flowers of all the ſpecies are papilionaceous, or butterfly-ſhaped, having four irregular petals, i. e. a vexillum, or ſtandard, two ſide wings, and a keel at bottom, ſucceeded by a long compreſſed pod filled with pea-like ſeeds.

The

The plants are proper ornamental furniture for any of the compartments of the pleaſure-garden, as they proſper in any common ſoil; but they muſt be allowed ſupport to climb upon, for they will climb by their claſpers, or cirrhi, on any neighbouring ſupport, ſuch as ſticks, buſhes, trees, or any thing they can lay hold of; ſo ſhould be ſowed in patches about the borders, and branchy ſticks, ſuch as is uſed for ſticking peas, placed for them to aſcend upon, and they will flower beautifully all ſummer and autumn. The everlaſting pea is alſo proper to be placed to run up the ſides of arbours and trees, and againſt walls and other fences, where it will have a very fine effect.

*Propagation, &c.*

Propagation of all the ſorts is by ſeed in the common ground in patches, where it is deſigned the plants ſhould flower, for they do not ſucceed ſo well by tranſplantation.

They ſhould be ſowed principally in ſpring, though if ſowed in autumn, the plants will flower earlier the following year, and the perennial ſort once ſowed, the ſame plants remain for years by the root, and produce new ſtalks annually; but the annual ſpecies muſt be ſowed annually, and that in order to continue a ſucceſſion of bloom from the earlieſt part of ſummer, until the end of autumn, three or four different ſowings is neceſſary; the firſt ſowing may be in autumn in November or December, or very early in ſpring; a ſecond in March or April; and a third in May, &c. by which you will have plants producing flowers in conſtant ſucceſſion three or four months.

Sow each ſpecies and variety in ſeparate patches, five or ſix ſeeds in each, about an inch deep; when the plants are come up a few inches high, place ſome neat branchy ſticks of proper height to each patch of plants for them to climb upon, and keep them clean from weeds, which is all the culture they require.

The firſt may alſo be propagated by tranſplanting ſome of the roots in autumn, winter, and ſpring; but thoſe rarely ſucceed ſo well as ſowing the ſeeds where the plants are to remain.

LAVANDULA, Lavender.

The plants are principally under-ſhrubby ever-greens, proper both for oeconomical uſes of a family, and for the ſhrubbery and green-houſe, growing two or three feet high very branchy and buſhy, cloſely ornamented with ſmall leaves; in ſome entire, others divided; and numerous ſmall monopetalous labiated flowers in erect ſpikes.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, is monophyllous and ſlightly indented. COROLLA, is monopetalous, tubulous below, ringent, and ſpreading above, the upper lip bifid; the under one equally trifid. STAMINA, two large and two ſhort filaments, and ſmall antheræ. PISTILLUM, a four-parted germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, none, four ſeeds lodging in the calix.

There are three ſpecies cultivated in the Engliſh gardens; two for the open ground, and one for the green-houſe.

[1]LAVANDULA *Spica.*

*Spikeflowered common Lavender, or Lavender Spike.*] Hath a ſhort ſhrubby ſtalk, cloſely branching from the bottom two or three feet high; ſmall ſpear-ſhaped entire leaves; and from the ends of the branches, numerous, long, erect, naked ſpikes of ſmall ringent flowers, of different colours in the varieties.

*Varieties.*] Common narrow-leaved Lavender, with blue flowers, and with white flowers—broad-leaved Lavender—dwarf Lavender: all of them flowering in July.

This ſpecies is the common Lavender, but the narrow leaved variety, with blue flowers, is the ſort commonly cultivated for its flowers for medicine, &c.

[2]LAVANDULA *Stœchas.*

*Common Stœchas, or French Lavender.*] Hath a ſhrubby very branchy ſtalk, riſing two or three feet high; very narrow ſpear-ſhaped, pointed, hoary leaves, oppoſite; and all the branches terminated by ſhort buſhy ſpikes of purple flowers in June and July; ſucceed by ſeeds in Auguſt.

*Variety.*] With white flowers.

[3]LAVANDULA *Dentata.*

*Dentate-leaved Stœchas.*] Hath a woody ſtalk, branching on every ſide three or four feet high; leaves deeply indented in a pinnated manner; and the branches terminated by ſcaley four-cornered ſpikes of flowers, appearing moſt part of ſummer.

All theſe plants are ſhrubby, durable in root, ſtem, and branches, and will indure ſeveral

ſeveral years in a moderately dry ſoil; but in a very moiſt ſoil are apt go off in winter.

The two firſt ſpecies are proper both for the kitchen-garden, for medical and other family uſes; and to plant in the pleaſure-ground to adorn the front of ſmall ſhrubbery compartments, where they will encreaſe the variety very agreeably; and are finely-ſcented aromatics, both when growing, and their flowers when gathered, eſpecially thoſe of the firſt ſpecies, which are in great eſteem for putting among cloaths, and diſtilling and other oeconomical uſes.

The flowers of the firſt ſort, are gathered for uſe in July, which being the time of their perfection, cutting off the ſpikes cloſe in a dry day, and tie them in ſmall bunches for uſe.

The above two ſorts ſhould generally be planted in a warm dry ſoil, in which they will be of the longeſt duration.

The third ſort being tender requires ſhelter in winter, ſo muſt be potted and placed in the green-houſe collection, where it will effect a good variety.

*Propagation, &c.*

All the ſorts are propagated plentifully by ſlips or cuttings of their young ſhoots in ſpring.

In March or April, take off a quantity of ſlips or cuttings, from three or four to ſix inches long, ſtrip off the under-leaves, then plant them in a ſhady border, four inches aſunder, give a good watering, repeat it occaſionally in dry weather, and the plants will be well rooted in ſummer, each become a good plant fit to be tranſplanted into any place early in autumn, that is September or October; removing them, if poſſible, with balls of earth, and if intended to plant them for uſe, ſet them in rows two or three feet aſunder, and two feet diſtance in each row; if any are deſigned for the ſhrubbery, they ſhould be ſtationed ſingly at good diſtances near the front.

Thoſe of the third ſort ſhould be potted to move to ſhelter in winter.

The *Lavendula Stœchas* is alſo often raiſed from ſeed. Sow them in March or April, in a bed of light earth, and rake them in evenly with a light hand; the plants will riſe in about a month; if dry weather, give water, and when they are three inches high, prick them out in beds, half a foot apart, and water them as they ſhall require until freſh-rooted; let them ſtand here till next ſpring; then you may thin out the beſt, and plant them where they are to remain.

LAVATERA, *Lavatera.*

This genus compriſes ſome tall herbaceous flowery annuals, and ſhrubby perennials, for the pleaſure-garden; all of them growing erect, from two or three to eight or ten feet high, garniſhed with large roundiſh heart-ſhaped, and angular leaves, and large quinquepetalous flowers, of the mallow kind.

Claſs and order, *Monadelphia Polyandria.*

*Characters.*] CALIX, is double and permanent, the exterior part is of one ſemitrifid leaf, and the interior is quinquefid. COROLLA, five obcordate, plane, ſpreading petals. STAMINA, numerous monadelphous filaments, and kidney-ſhaped antheræ. PISTILLUM, an orbicular germen, ſhort ſtyle and many briſtley ſtigmas. PERICARPIUM, numerous ſmall capſules collected into a head covered with a hollow ſhield, each capſule having a kidney-ſhaped ſeed.

The moſt noted ſpecies are the following annuals and perennials.

*Annual Kinds.*

[1]LAVATERA *Cretica.*

*Cretan Annual Lavatera.*] Riſes with an upright, branching, herbaceous ſtalk, two or three feet high, the lower branches very diffuſe or ſpreading; large, roundiſh, lobated leaves, the upper ones acutely trilobate; and the foot-ſtalks of the flowers riſing in cluſters from the axillas of the leaves, each ſupporting one large flower of different colours in the varieties.

*Varieties are*] Cretan Lavatera with red flowers—white flowers—and with purpliſh flowers.

[2]LAVATERA *Trimeſtris.*

*Spaniſh Lavatera*] Riſes with a ſlender, herbaceous, rough ſtalk, branching two feet high; trilobated ſmooth leaves, having oval-lanceolate lobes, the middle lobe much the longeſt; and pale-red flowers, ſingly on ſhort foot-ſtalks.

*Perennial Shrubby Kinds.*

Theſe have tall ſtraight, ſomewhat ſhrubby, perennial ſtems, of ſeveral years duration in dry ſoils.

[3]LAVATERA *Arborea.*

Tree-

*Tree-Lavatera, commonly called Tree-Mallow.*] Riſes with a thick, ſtrong, perennial ſtem, eight or ten feet high, dividing at top into many branches; large, ſeven-angled, plaited, ſoft, woolly leaves; and from the axillas, cluſters of ſhort foot-ſtalks, each ſuſtaining one large purple flower, appearing in ſucceſſion from June till September.

4 LAVATERA *Triloba.*

*Trilobate Shrubby Lavatera.*] Riſes with an upright, thick, branchy, perennial ſtem, the branches numerous and ſpreading; trilobate, and ſubcordate-roundiſh, crenated, woolly leaves; and aggregate foot-ſtalks, each ſuſtaining one light purple flower.

5 LAVATERA *Albia.*

*Albian Five-lobed Shrubby Lavatera.*] Riſes with an upright, branching, perennial ſtalk, five or ſix feet high; large five-lobed, ſoft, woolly leaves; and light-purple flowers, growing ſingly.

The flowers of all the ſpecies, are large, compoſed each of five broad petals, and grow on foot-ſtalks from the joints of the ſtem and branches, in great numbers, continuing in ſucceſſion from June until Auguſt or September, ſucceeded by plenty of ſeed in autumn.

The plants in general are of hardy growth, and ſucceed in any of the open borders; the annuals are only of one ſummer's duration, the perennials of ſeveral years, both in root and ſtem.

They are all proper ornaments for any part of the pleaſure-ground.

The annuals particularly have ſingular beauty, their flowers being large, numerous, and conſpicuous, and very proper furniture where large ſhowey plants are required; and are eaſily and abundantly raiſed from ſeed in the open ground.

The ſhrubby kinds are alſo good furniture for ſhrubbery compartments, having large, ſtraight, upright, durable ſtems, terminated by branchy buſhy heads, and very large ſoft foliage, that form a fine variety in aſſemblage; though their flowers are often hid by their large leaves. Theſe perennial kinds ſhould have a dry ſoil, otherwiſe are apt to go off in two or three years; a freſh ſupply, however, may always be eaſily raiſed from ſeed in the common ground.

*Propagation of all the Sorts.*

They are propagated abundantly by ſeed in the open ground in the ſpring; the annuals in the place where ſowed, and the perennials alſo either where they are to remain, or for tranſplantation.

The annuals ſucceed generally beſt when ſown where it is deſigned they ſhall flower, either in the borders, or in pots. Sow them in ſpring, any time from February till May, in patches, four or five ſeeds in each, half an inch deep; when the plants are an inch or two high, thin them to two or three in each patch, or if only one in a place, the plants will be the ſtronger and more branchy; the ſame method is to be obſerved in ſowing them in pots.

If intended to tranſplant any of theſe kinds from one place to another, it ſhould be done while the plants are young, about three or four inches high, for their roots being long and not very fibrey, they do not ſucceed ſo well by tranſplantation, as plants with more fibrey roots.

The perennials are alſo raiſed plentifully by ſeed in a bed or border of light earth, either in patches, as above, to remain, or may be ſowed for tranſplantation, by broadcaſt, and raked in, or in ſhallow drills, half a foot aſunder; and when the plants, ſowed in either method for tranſplanting, are three or four inches high, plant them out at once in the places where they are to remain, or may be planted in nurſery beds, to remain till autumn or ſpring, or till wanted.

LAURUS, Bay Tree.

This genus furniſhes ſome eminent evergreen and deciduous trees, both for ornamental plantations and the green-houſe, growing from ten or fifteen to twenty or thirty feet high; garniſhed with largiſh, oblong, moſtly entire leaves, and ſmall hexapetalous hermaphrodite flowers.

Claſs and order, *Enneandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, ſix oval, concave, acuminated, erect petals. STAMINA, nine filaments ſtanding by threes, and ſmall antheræ. PISTILLUM, an oval germen, ſingle ſtyle, and obtuſe ſtigma. PERICARPIUM, an oval, acuminated, unilocular berry, containing an oval ſharp-pointed nut or ſeed.

There are about ſeven or eight ſpecies of this genus, all of them natives originally of foreign parts; the common Bay, that of the ſouth of Europe, the others of America and Aſia; and of which ſpecies three are hardy, and the reſt for the green-houſe; of the hardy

hardy kinds, one is a beautiful ever-green, and two deciduous, and the green-houſe ſorts are principally of the ever-green tribe.

*Hardy Ever-green Kinds.*

[1]LAURUS *Nobilis.*

*Noble Ever-green Laurus, or Common Bay-tree.*] Hath an upright trunk, branching on every ſide from the bottom upward, riſing twenty or thirty feet high; ſpear-ſhaped, nervous, ſtiff, ever green leaves, three inches long and two broad; and ſmall, yellowiſh, quadrifid, dioecious flowers; ſucceeded by red berries in autumn and winter. Is a native of Italy, &c. but has been long in the Engliſh gardens.

*Varieties.*] Broad-leaved Bay-tree—waved-leaved Bay-tree—narrow-leaved Bay-tree—ſtriped-leaved Bay-tree.

The broad-leaved ſort is often preſerved in the green-houſe collection, but all the ſorts may be inured to the open air all the year the ſame as the common Bay.

*Hardy Deciduous Kinds.*

[2]LAURUS *Æſtivalis.*

*Æſtival, or Deciduous Bay.*] Riſes with an upright ſtem, branching eight or ten feet high, covered with a purpliſh bark; oblong-oval, acuminated, veined, deciduous leaves, two or three inches long, half as broad, growing oppoſite; and ſmall white flowers; ſucceeded by red berries, but none in England. Is a native of North America.

[3]LAURUS *Benzoin.*

*Benjamin-tree.*] Grows fifteen or twenty feet high, dividing into a very branchy head; oval, acute, unveined, deciduous leaves; three or four inches long, and half as broad; and ſmall yellowiſh flowers, not ſucceeded by berries in England. Is a native of North America.

From this tree is ſaid to be procured the medical ſubſtance, called Benjamin.

[4]LAURUS *Saſſafras.*

*Saſſafras-tree.*] Hath a ſhrub-like ſtraight ſtem, branching ten or fifteen feet high; garniſhed with both oval, and three-lobed, ſhining, deciduous leaves, of different ſizes, from three or four to ſix inches long, and near as broad; and ſmall yellowiſh flowers; ſucceeded by blackiſh berries, but not in England. Is a native of North America.

The wood of this tree is very fragrant, and is eſteemed a great antiſcorbutic; and uſed in infuſion, like tea, is a very powerful purifier of the blood; for which purpoſe great quantities of the wood is brought hither from America, and is commonly cut or raſped into chips for uſe. In London the infuſion thereof, in the manner of tea, is ſold in the ſaloop-ſhops, and about the ſtreets, inſtead of ſaloop, or ſalep; but it is ſaid that too conſtant uſe of it occaſions the head-ach.

*Green-houſe Kinds.*

[5]LAURUS *Indica.*

*Indian Bay-tree.*] Riſes with an upright ſtraight trunk, branching regularly twenty or thirty feet high; adorned with very large ſpear ſhaped, plane, nervous, ever-green leaves, on reddiſh foot ſtalks; and bunches of ſmall whitiſh-green flowers; ſucceeded by large oval black berries; but do not ripen in England.

[6]LAURUS *Borbonia.*

*Borbonia, or Carolina Red Bay-tree.*] Riſes with an upright ſtraight ſtem, branching fifteen or twenty feet high; large, ſpear-ſhaped, ever-green leaves, tranſverſely veined; and long bunches of flowers, on red foot-ſtalks; ſucceeded by large blue berries, ſitting in red cups.

[7]LAURUS *Camphora.*

*Camphora, or Camphire-tree.*] Riſes with a large trunk, dividing into a very branchy head, twenty or thirty feet high; ſpear-ſhaped-oval, triple-nervous, ever-green leaves; and ſmall yellowiſh flowers, ſucceeded by black berries; but none in England. It is a native of Japan.

Every part of this tree imparts a fragrant ſmell of camphire, and the ſubſtance of that name is got by diſtilling the root and wood with water, in an alembic, having a kind of twiſted ſtraw head, thro' which the humidity evaporates, and the camphire ſticks to it.

[8]LAURUS *Cinnamonum.*

*Cinnamon-tree.*] Riſes with an upright, branching ſtem, fifteen or twenty feet high; oval-oblong, trinervous leaves; and whitiſh flowers in cluſters; ſucceeded by oval berries, but none here. Is a native of India and Egypt; and it is the bark of this tree that is the cinnamon of the ſhops; which grows in great plenty in the Iſland of Ceylon in the Eaſt Indies, from whence the Dutch ſupply us and other European markets with that commodity.

The flowers of all the ſpecies of Laurus are ſmall, conſiſting of ſix petals, grow uſu-

ally in clusters, but have no beauty; and appear in spring and summer, which in the common Bay are succeeded here by plenty of berries; but in the other sorts, rarely any seed in England.

All the species are of the tree and shrub kind, and merit admittance in every good collection. The three hardy sorts are proper for all ornamental plantations, and will succeed any where in common with other hardy trees and shrubs; and the tender kinds will exhibit a fine variety among the green-house exotics.

The *Laurus Nobilis*, noble or common Bay-tree, is indeed a noble ever-green tree, as well as a fine aromatic, has been long an inhabitant of our gardens, and is extremely proper for any of the shrubbery plantations, where, it being a lively ever-green, it will effect a fine variety at all seasons of the year. Some of the varieties of this tree are also sometimes retained as green-house plants, particularly the broad-leaved and narrow-leaved kinds, which by former botanists were considered as distinct species, but they are now found to be only varieties of the common Bay; and like that sort, may be innured to the open air all the year; remarking that even the common sort, as well as these, is apt to suffer in its young branches in very rigorous winters; therefore, if thought convenient, some of the above varieties may also be potted to have shelter in winter, and to encrease the variety of the green-house collection.

As this tree in its several varieties is apt to throw out many suckers from the bottom, so as sometimes to form a thicket, to have the trees grow with handsome straight stems, and regular heads, the suckers should be all cleared away, and those of them that are taken off with roots, if planted, will form good plants.

The other hardy kinds, deciduous Bay, and the other two deciduous sorts, the *Laurus Benzoin* and *Sassafras*, also succeed in the open ground all the year, which for their singularity merit admittance in every shrubbery; and the nature and beauty of their fine foliage will contribute exceedingly to the variety of the deciduous plantations.

The green-house kinds requiring shelter here in winter, must always be kept in pots; they are all fine plants, and should never be wanting in curious green-house collections: pot them in rich light mould, and place them in the green-house all winter, and in the open air in summer. See GREEN-HOUSE Plants.

But the cinnamon is also sometimes retained as a stove-plant: it will, however, succeed in the open air in the heat of summer, and in a good warm green-house in winter, especially such as are accommodated with flues, &c. to have fires in severe weather.

*Propagation, &c. of all the Sorts.*

The common Bay is propagated by seed, layers, and suckers.

By Seed —This should be sowed soon after the beries are ripe, or early in spring, either in beds, covering them with earth near an inch deep, or in drills half a foot asunder, the same depth; the plants will come up late the same spring; observing to supply them with frequent watering during summer, and in winter defend them from severe frost, by shelter of mats, or some other covering, they being tender while young: and after having two summer's growth in the seed-bed, then, in the spring following, transplant the strongest in nursery-rows, two feet asunder, and a foot apart in each row; giving water in dry weather, till they have taken good root, and hoe down weeds in summer. Here they may remain till half a yard, or two or three feet high, and then planted out into the shrubbery in autumn or spring.

If the berries are sowed in pots and plunged in a hot-bed in spring, it will bring the plants forwarder, being careful to innure them to the full air in summer.

By Layers.—Lay down some of the lower branches that are well furnished with young shoots; each of which shoots are to be slit-layed, to form plants: they will be rooted in one year; then in spring take them off, and plant them in the nursery as directed for the seedlings.

By Suckers.—These should be taken up with good roots in autumn or spring, and planted in the nursery like the seedlings and layers.

The propagation of the deciduous Bay, Benjamin and Sassafras-tree, is by seed, by layers, and sometimes by suckers and by cuttings The seeds or berries are procured from America, preserved in sand; which should be sowed as soon after they arrive as possible, because they often lie a year before they germinate: sow them in a bed of light earth an inch deep, or may sow them in largish pots the same depth, plunging them in mould in an

an eaſt border up to their rims, till ſpring following, and if then placed in a hot-bed, it will greatly forward the germination of the ſeed, and ſoon bring up the plants; but they muſt be timely innured to the full air: the young plants raiſed by either method, ſhould be watered during ſummer, and ſheltered from froſt in winter, like the common Bay-ſeedlings; and when two years old, plant them out in nurſery rows, as directed for thoſe plants. The propagation of theſe two ſorts by layers and ſuckers, is the ſame as directed for the Bay-tree, but it is ſometimes two years before the layers are rooted.

Cuttings of them will ſometimes put out roots by aid of a good hot-bed.

The green-houſe kinds are propagated commonly by layers, but they are often two years before they are ſufficiently rooted. They may alſo be raiſed from ſeeds, procured from the places of their growth abroad, and ſow them in pots; they rarely grow the firſt year, ſo place them in the open air in ſummer, and in the green-houſe, near the windows, in winter; and in ſpring place the pots in a hot-bed, which will bring up the plants, giving air daily, and frequent waterings, and innure them by degrees to the open air as the ſummer advances; place them in ſhelter in winter, and in ſpring plant them in ſeparate ſmall pots, managing them as other green-houſe ſhrubs, &c.

LAWN, a ſpacious open plain of graſs-ground, in a garden or park, and generally made to extend immediately in the front of the manſion of a country ſeat.

A noble lawn of graſs extended in the principal front of the habitation, adds conſiderably to the grandeur of the garden and ſcite in general, and beauty of the manſion, by laying it open to the neighbouring country, as well as admitting of extenſive proſpects; ſo that where there is ſcope of ground, a ſpacious Lawn, as large as the nature of the garden admits, ſhould always be planned in the moſt conſpicuous part immediately adjoining the houſe, and may be extended outward as far as ſhall be convenient, even beyond the limits of the garden, in large eſtates, continuing it forward to the utmoſt boundary of a park, or paddock, or as far as the view from the houſe ſhall extend, allowing width in proportion; having each ſide bounded by noble rural plantations, interſperſed with ſerpentine walks, and open ſpaces both of graſs and gravel, of different forms and dimenſions, for places of retirement, ſhade, and ornament.

The ſituation of a Lawn ſhould generally be directly on the main front of the dwelling, if the nature of the ground admits; or in ſome caſes, where there is good ſcope of ground, it may be continued more or leſs each way, but always the moſt conſiderably on the principal front, if the ſituation allows it, which if it fronts the ſouth, or towards any of the ſoutherly points, is the moſt deſirable aſpect for a complete Lawn.

The dimenſions may be from about a quarter of an acre to ſix or eight, according to the extent and ſituation of the ground, and in large eſtates, having a park, &c. adjoining, the Lawn is often extended over ha-ha's beyond the garden, ſometimes to ten, twenty, or even to fifty or ſixty acres, or more.

As to figure, it is very commonly oblong, ſometimes ſquare, oval, or circular, all of which may be according to fancy, or to the figure of the ground; but ſomewhat of the oblong form is rather the moſt elegible; and in whatever figure the Lawn is deſigned, it ſhould widen gradually from the houſe outward to the fartheſt extremity, to have the greater advantage of proſpect; having both ſides bounded by rural ſhrubbery plantations, as before obſerved; continuing the homeward part of the plantation on each ſide, gradually round toward each wing of the houſe, that company may ſooner arrive in the walks of the plantation under ſhade, ſhelter, and retirement, when required; and the termination at the farther end, may be either a ha-ha, to extend the proſpect, if there ſhall be an agreeable one; otherwiſe, if there is no good view beyond the extreme limits, it may terminate in a ſhrubbery; or if the Lawn is very extenſive, and no inviting proſpect beyond the extreme boundary, the termination may be a plantation of ſtately trees, arranged in conſiderable ſweeps and concave curves, that the imagination may conceive the view to be ſwallowed up in wood. When, however, the Lawn extends towards any great road, or diſtant agreeable proſpect, ſo as to command views thereof, it is more in character to have the utmoſt verge open, ſo as to admit of a grand view to the manſion.

The ſide boundaries of the Lawn ſhould be formed with plantations of curious ſhrubs and trees, diſpoſed in clumps, alternately deciduous and ever-greens; not in cloſe re-

gular arrangement, but in rural diſpoſition, in imitation of nature, in irregular elegant clumps, with irregular breaks, or opens of graſs-ground between, communicating with the lawn, for views, &c. the clumps to be of different dimenſions, variouſly formed, having ſome parts in grand projecting ſweeps advancing toward the Lawn, others in concave curves the contrary way, all varying in their dimenſions, poſition, and direction, to appear more rural, and to take off all ſtiff formal appearance, both from the figure of the Lawn and plantations; obſerving, as above, to plant the clumps, with deciduous and evergreen plants alternately; and place the lower growth of ſhrubs towards the front, and the taller backward in proportion to their ſeveral ſtatures, ſo as to exhibit a regular gradation of height, that the different ſorts may appear from the Lawn; and may be continued backward to ſome conſiderable depth, and backed with the moſt lofty trees; through the internal parts of the plantation may be gravel or ſand walks, ſome ſhady, others open; with here and there ſome ſpacious graſs openings, of different dimenſions and figures.

The homeward part of a Lawn, however, ſhould always have each ſide-verge ornamented as above, with plantations, which as the Lawn extends may gradually diminiſh.

Very extenſive Lawns in parks or paddocks, &c. have the ſurface ſometimes dotted with noble trees, diſperſed in different parts, at great diſtances not to obſtruct the view; ſome placed ſingly, others in groups by twos, threes, fives, &c. and ſome placed irregularly, ſome in triangles, ſweeps, ſtraight lines, and other different figures, to cauſe the greater variety, each group generally diverſified with different ſorts of trees, all ſuffered to take their own natural growth.

The graſs of the Lawn, and other graſs-ground communicating therewith, may be formed either by ſowing graſs-ſeed, or by laying with turf; but in very extenſive works turfing would be very expenſive, therefore ſeed is the moſt eligible; eſpecially in that part of the Lawn which is extended beyond the garden. See GRASS.

It ſhould always be kept perfectly neat, particularly the home Lawn within the garden, which ſhould be often poled and rolled all the year, and in ſummer well mowed, once a week at leaſt. See GRASS.

LAYING, the propagation by layers, is particularly adapted for almoſt all ſorts of trees and ſhrubs and many herbaceous plants.

The propagation by layers is effected by laying branches and young ſhoots of trees and plants in the earth, from two or three to five or ſix inches deep, leaving their tops out; and that part layed in the earth emits roots, ſome ſorts in from two or three to five or ſix months, others a year, and ſome are two years before they are ſufficiently rooted, and each layer ſo rooted commences a new plant, which are then to be ſeparated from the parent, and planted in the nurſery way to acquire due ſtrength and ſize, for the purpoſes for which they are calculated. See the method of performing the operation.

Vaſt numbers of ſhrubs and trees are propagated by Layers; but is more particularly applicable to the increaſe of numbers of the ſhrub kind; becauſe their branches grow near the ground, convenient for Laying: it may alſo, however, be practiſed with equal ſucceſs on fruit-trees and foreſt-trees, when their branches are ſituated low enough for Laying; though the varieties of fruit-trees are commonly propagated by grafting and inoculation, the vine and fig, however, often by Layers; and foreſt-trees, for the general part, by ſeed, except for the continuance of varieties, then it is performed either by layers, cuttings, grafting, or budding; for plants raiſed by all theſe methods, continue exactly the ſame in every reſpect, as the parent plant from whence they were raiſed; for, as obſerved on former occaſions, many ſorts of plants, when raiſed from ſeed, vary ſo greatly, that out of numbers very few may be like the original, or parent plant, as obſerved under the article GRAFTING, &c. ſo that Laying is a certain method both to continue any approved variety, as alſo to encreaſe ſuch ſhrubs or trees that do not produce ſeeds here, and which cannot be eaſily obtained; likewiſe is both an expeditious and plentiful mode of propagation; for by layers, many new plants are often raiſed in a few months, that would take two or three years to to raiſe them the ſame ſize from ſeed; and in many ſorts ſo abundantly, that all the ſhoots of any branch ſituated near the ground, or convenient for Laying, may be made each a diſtinct plant.

The Laying for all ſorts of the tree or ſhrub kinds, is generally performed on the young

young ſhoots of the preceding ſummer; layed in ſpring or autumn; and ſometimes on ſhoots of the ſame year, in ſummer, eſpecially of many ſorts of hard-wooded ever-green trees and ſhrubs, that do not ſtrike root readily in the older wood; which is generally mentioned in the culture of the reſpective ſorts. Though many ſorts of trees having their wood of a ſoft looſe texture, layers of them of ſeveral years growth, will often grow pretty freely; but for general Laying for moſt ſorts, the young wood of the former year is the proper part for that operation.

But in herbaceous plants propagated by layers, ſuch as carnations, pinks, double ſweet-williams, &c. the young ſhoots of the ſame year, in June and July are commonly the moſt ſucceſsful for layers.

The ſeaſon for performing moſt ſorts of tree and ſhrub Laying, is autumn and ſpring, though it may be performed at almoſt any time of the year, but the moſt general ſeaſon is any time from October till March, only excepting, as above obſerved: ſuch hard-wooded plants that are found not to ſucceed by the common method of Laying in the one-year's ſhoot, at the above ſeaſon, ſhould be layed in the ſame ſummer's ſhoot in June or July, while it is tender, before it becomes woody, and it will often be rooted by the end of the ſame ſummer.

Many kinds of under-ſhrubby and herbaceous plants will alſo ſucceed, if layed any time in ſpring or ſummer till the end of June; though June and July is the moſt ſucceſsful for ſuch of the herbaceous tribe, as carnations and others uſually propagated by Laying: it is, however, but few herbaceous plants that are propagated by that method, it being readily effected in many ſorts, to continue the varieties, by ſlips, off ſets, or parting the the roots, which is always mentioned; and by which the varieties of theſe kinds are continued the ſame as by Laying.

When intended to lay any trees or ſhrubs that naturally run up with ſtems, without furniſhing any conſiderable quantity of lower branches for Laying, a ſufficient number of ſtrong plants ſhould be ſet in the nurſery, at proper diſtances, and headed down in autumn after, within a few inches of the ground, that they may throw out a good quantity of young ſhoots the following ſummer, convenient for Laying the ſucceeding autumn; or, if you wait another year, you will have many more ſhoots for the purpoſe of layers, by the firſt ſhoots throwing out many lateral ones, and each of which layed will form a plant; and the Layers being rooted, and all cleared away, the ſtool remaining will furniſh another crop of ſhoots for Laying next year.

But when layers are required from any trees that are grown up, and whoſe branches are at a diſtance from the ground, a temporary ſtage or ſcaffold is erected, on which to place pots or tubs of mould to receive the Layers.

One general method of merely Laying the branches or ſhoots in the earth, is practiſed for all ſorts, as directed below; but previous to laying, they are often prepared different ways to facilitate their rooting, according as the trees of different natures require; as by ſimple Laying, twiſting, ſlitting, cutting the bark, piercing the ſhoot, and by wireing, &c. as follows:

By Simple Laying.—This is only ſimply Laying the ſhoots in the earth, as hereafter directed, without any previous preparation of twiſting, ſlitting, &c. and is ſufficient for vaſt numbers of trees and ſhrubs of the ſoft-wooded kinds: but ſuch as do not readily root by this ſimple method, muſt have recourſe to ſome of the following ways, and the ſorts which require it is generally mentioned under their proper genera.

By Twiſting the Layer.——By giving the ſhoot a gentle twiſt in the part deſigned to be layed, it greatly promotes and facilitates the emiſſion of fibres from the bruiſed parts; and layers of numerous trees and ſhrubs may be forwarded exceedingly in rooting by this method.

By Slitting, or Tonguing the Layer.——This is the moſt univerſal and generally moſt ſucceſsful mode, where any preparation of the ſhoot is neceſſary to promote its rooting; it is performed by ſlitting the ſhoot at a joint, up the middle, half an inch or an inch or more long, according to the ſize and nature of the Layer, forming a ſort of tongue, nearly the ſame as directed for carnation Layers; Laying that part in the earth, and raiſe the top upright, or rather pointing inwards, ſo as to ſeparate the tongue of the ſlit from the other part, and keep the ſlit open; then apply the earth about the Layer, as here under directed.

By Cutting the Bark.—This is done by cutting the bark all round at a joint, taking out ſmall chips thereof all the way below the cut, and Laying that part in the earth, it will readily

readily emit roots; in ſome ſorts more freely than by any other preparation.

By Piercing the Layer.—Thruſt an awl through the ſhoot at a joint in ſeveral places, Laying that part, and it will emit fibres from the wounds.

By Wireing the Layer.—Twiſt a piece of wire hard round the ſhoot at a joint, and prick it with an awl on each ſide of the wire in ſeveral places, Laying it in the earth, it will break out into roots at the confined and wounded parts; and often proves ſucceſsful to ſuch trees and ſhrubs that do not readily emit fibres by the other methods.

By one or other of the above methods, almoſt all ſorts of trees and ſhrubs may be propagated.

Always keep in mind that the young ſhoots of one or two years growth are the proper parts for Laying, either ſuch ſhoots riſing immediately from the bottom, properly ſituated for Laying; or large lower branches furniſhing plenty of ſuch ſhoots, ſhould be layed down, and all the ſhoots on it made layers, and the following is the method to be practiſed for Laying all ſorts.

The general method of Laying all ſorts of trees or plants, either by ſimple Laying as above, or by any of the other above methods, in reſpect to the preparation of the ſhoots, is in the following manner: the ground round each plant intended for Laying, muſt be digged, and excavated for the reception of the Layers; then lay down in the earth all the ſhoots or branches properly ſituated for this purpoſe, peg each down with a hooked ſtick; laying alſo all the proper young ſhoots on each branch or main ſhoot; fixing each layer from about three or four to ſix inches deep, according as they admit, and directly mould them in that depth, leaving the tops of every layer out of ground, from about two or three to five or ſix inches, according to their length, though ſome ſhorten their tops down to an eye or two only above the earth; obſerving to raiſe the top of each Layer ſomewhat upright, eſpecially the ſlit, or tongued Layers, to keep the ſlit part open; according as all the Layers of each plant, or ſtool, are thus Layed, level in all the mold finally, and equally in every part cloſe about every Layer, leaving an even ſmooth ſurface, with the top of each Layer out, as above directed.

Sometimes the branches of trees are ſo inflexible as not to be eaſily brought down for Laying; in which caſe they muſt be ſplaſhed, making the gaſh or cut on the upper ſide; and when they are grown too large for ſplaſhing, or that the nature of the wood will not bear that operation, they may be thrown on their ſides, by opening the earth about the roots, and looſening or cutting all thoſe on one ſide, that the plant may be brought to the ground to admit of Laying the branches.

When layers are to be made from greenhouſe ſhrubs, or other plants in pots, the Laying ſhould generally be performed in pots, either of their own, or others placed for that purpoſe.

After Laying in either of the above methods, there is no particular culture neceſſary, except in the heat of ſummer, to give occaſional waterings to keep the earth moiſt about the layers, which will greatly forward them, and promote a good ſupply of roots againſt autumn, when thoſe that are properly rooted ſhould be tranſplanted.

We before noticed, that ſome ſorts will be properly rooted in the autumn after Laying, and ſome require two years: examine them at the proper ſeaſon, October and November, and let thoſe that are rooted be cut from the main plant, with all the root poſſible, and plant them out in nurſery rows, a foot or two aſunder, according to their nature of growth, there to remain till of due ſize for their ſeveral purpoſes; but thoſe of tender quality muſt be potted, and placed among others of ſimilar nature.

When the layers are all cleared from the ſtools or main plants, the head of each ſtool, if to be continued for furniſhing Layers, ſhould be dreſſed; cutting off all decayed and ſcraggy parts, and dig the ground about them, and ſome freſh mould worked in cloſe about the head, to refreſh and encourage their producing a freſh ſupply of ſhoots for next year's laying.

LEGUMEN, Legum, or Pod, a ſpecies of ſeed-veſſel, ſuch as that of the pea, bean, kidney-bean, &c.

A Legumen, or pod, is a ſeed-veſſel generally oblong, having two valves, or external openings, incloſing a number of ſeeds that are faſtened along one future only, or joinings of the valves, and differs from that kind of pod, by the botaniſt termed *ſiliqua*, by the latter having the ſeeds faſtened to both ſides of the ſutures. See SILIQUA.

All the papilionaceous flowered plants, have a Legumen, for their ſeed-veſſel, exemplified

fied in the pea, bean, kidney-bean, &c. See PAPILIONACEUS.

LEUCOJUM, Great Snow-drop.

The plants are bulbous-rooted, herbaceous, flowery perennials, proper for the open borders, riſing with annual ſtalks a foot high, terminated by hexapetalous white flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters* ] CALIX, an oblong compreſſed ſpatha opening on the ſide. COROLLA, is bell ſhaped, ſpreading, and of ſix oval petals. STAMINA, ſix ſhort briſtly filaments, and four-cornered erect antheræ. PISTILLUM, a roundiſh germen under the corolla, obtuſe, clavated ſtyle, and an erect briſtly ſtigma. PERICARPIUM, a turbinated trivalvular, trilocular capſule, containing numerous roundiſh ſeeds.

In this genus former botaniſts ranged alſo the galanthus, or common winter ſnow-drop, by ſome reſemblance in their flowers, but they are very different from each other, in that the flowers of *Leucojum* have ſix petals, and the *Galanthus* but three, accompanied by a very ſingular nectarium in the centre.

There are three ſpecies,——the ſpring-owering—ſummer-flowering—and autumnal flowering, viz.

[1] LEUCOJUM *Vernum.*

*Vernal, or Spring Leucojum.*] Hath an oblong bulbous root; ſending up ſeveral flat leaves, ſix or eight inches long; and amidſt them an upright, channelled, hollow, naked ſtalk, about a foot high, terminated by a ſpatha, protruding one or two flowers on ſlender foot-ſtalks, drooping downward; flowering in March.

[2] LEUCOJUM *Æſtivum.*

*Summer Leucojum.*] Hath a large, oblong, bulbous root; crowned with ſeveral long, flat, broad leaves; and amidſt them an upright, thick, hollow ſtalk, fifteen or eighteen inches high; terminated by a ſpatha, protruding many white flowers, on ſlender footſtalks, drooping downward; flowering in May.

[3] LEUCOJUM *Autumnale.*

*Autumnal Leucojum.*) Hath a large oblong bulbous root; crowned with many narrow leaves; an upright, naked, hollow ſtalk; terminated by a ſpatha, protruding many white flowers, on long weak foot-ſtalks hanging downward, and very ſlender ſtyle; flowers in autumn.

Of theſe three ſpecies the two firſt are the moſt common to the Engliſh gardens.

They are all very hardy, durable in root, but annual in leaves and ſtalks, which ariſe from the root in ſpring, and decay in ſummer, &c. ſoon after they have flowered; but the roots abide for years, and encreaſe exceedingly by off ſets, which may be ſeparated every two or three years.

Their flower-ſtalks riſe immediately from the root, naked or leafleſs, and the flowers ſtand at top, each conſiſting of ſix oval petals, that coaleſce at their baſe, each flower droops in a ſnow-drop manner, ſucceeded by plenty of ſeed.

Conſidered as flowery plants, they are pretty ornaments for the borders, or any of the compartments contiguous to the principal walks and home-lawns; the roots may be had at the nurſeries, plant them in autumn, towards the front, in patches of three roots in each, ſetting them three inches deep; they will flower the following year, at their uſual time; and the roots may remain unremoved two or three years, when they will be encreaſed by off-ſets into large bunches, then ſhould be taken up for ſeparating the off-ſets, and the largeſt roots planted again for flowering, and the off-ſets in nurſery-beds for a year or two.

Their propagation is by off-ſets of the roots, as juſt obſerved, which they afford in tolerable plenty, and may be ſeparated every third year, in ſummer when their leaves decay, like other bulbs. See BULBUS.

They may alſo be raiſed from ſeed, but the ſeedling plants will be three or four years before they flower. Sow it in Auguſt or September, in a border of light earth half an inch deep; the plants will riſe in ſpring, which in the ſecond ſummer ſhould be taken up at the decay of the leaf, and planted in beds till they flower, then removed to the borders.

LIGHT. Light and air are as neceſſary for ennobling the principles of vegetation as for animal oeconomy.

It has been experienced that light is of ſuch infinite ſervice to the growth of vegetables, that it contributes exceedingly, both to facilitate their vegetation, and encreaſe their perfection and duration, for it is obvious that moſt plants are conſiderably more proſperous, and attain greater perfection in a free expoſure fully open to the light and air, than in ſhady places; the ſame is obſerved of fruits. Thoſe growing in a ſituation full to the light of the ſun, are generally more large and fair, ripen ſooner, and more perfectly, both as to beauty,

beauty, and richneſs of flavour, than ſuch as grow in the ſhade; the above reaſons, therefore, ſhould determine us to cultivate moſt of our principal plants and fruits in a ſituation open as much as poſſible to the full light, and influence of the ſun; though upon particular occaſions in the heat of ſummer, a ſhady place may be neceſſary for ſome ſorts of plants; not, however, where ſhaded and darkened by ſpreading trees, &c. but a border open above to the full light, and only ſhaded from the immediate rays of the ſun; but for the general crops, a perfectly open, ſunny, lightſome ſituation, free from the ſhade of ſpreading trees, is always the moſt eligible.

It is alſo obſervable of plants growing in garden-frames, green-houſes, &c. in winter, when, in time of ſevere weather, covers or ſhutters have been obliged to be continued long over the glaſſes, ſo as to exclude the rays of light, the plants thereby, for want of light, ſicken, grow pale, and aſſume an unhealthy appearance for a long time, the leaves often either decay or drop off; and frequently when the covers are continued very long without the admiſſion of Light, the whole plant in many ſorts gradually dwindles and periſhes. Great attention is therefore requiſite, in this caſe, when the ſeverity of the weather obliges us to uſe other covers beſides the glaſſes, to take every opportunity of a favourable day, or even an hour or two of a day to admit the light.

The ſame is alſo obſervable to plants in early hot-beds, ſuch as cucumbers, melons, &c, which, early in the year, require a covering of mats over the glaſſes every night, that if theſe additional covers are applied too ſoon in the afternoon, and continued late in the morning, ſo as to keep the plants long in darkneſs, it is a very conſiderable diſadvantage to their growth; as will cauſe them to grow weak, pale, and ſickly. Let, therefore, the plants in thoſe beds enjoy the light every day as long as poſſible, at leaſt from the ſun's riſing to its ſetting, or longer, if the temperature of the heat of the hot-bed, and that of the external air ſhall permit; for tho' the plants in hot-beds alſo grow on nights when in total darkneſs, yet continue them ſo but two or three days, the difference in growth, for want of day-light will ſoon appear.

Light being, therefore, ſo beneficial to plants in general, that to encreaſe it as much as poſſible to thoſe in frames, green-houſes, ſtoves, &c. it is neceſſary to paint the inſide of all theſe departments white, to reflect the rays of light as much as poſſible, but more particularly on nights, and in the day-time when the ſeverity of the ſeaſon requires covers or ſhutters over the glaſſes.

LIGUSTICUM, Lovage.

It furniſhes ſome tall herbaceous perennials and biennials, retained in gardens for variety and medical purpoſes; riſing with very large, radical, many-parted leaves, and erect branchy annual ſtalks, ſome two yards high, others not half a yard, terminated by large umbels of yellow flowers of but little beauty.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, umbellate flowers, having both the general and partial umbel multiple, the general involucrum of ſeven unequal leaves, and the partial one three or four, and a ſmall five-parted perianthium to each floret. COROLLA, each floret of the umbel have five plane petals. STAMINA, five ſhort hair-like filaments, and ſimple antheræ. PISTILLUM, a germen under each floret, two ſtyles, and ſimple ſtigmas. PERICARPIUM, none, an oblong, angular, channelled, divided fruit to each floret, containing two oblong ſeeds.

The moſt material ſpecies are;

[1]LIGUSTICUM, *Leviſticum.*

*Leviſticum, or common Lovage.*] Hath a thick, fleſhy, deeply-penetrating perennial root; crowned by very large, many-parted, radical leaves, with broad lobes, having inciſions at top; upright, ſtrong, channelled ſtalks, branching ſix or ſeven feet high, and all the branches terminated by large yellow umbels.

This is the ſort commonly cultivated for uſe, and every part of the plant is aromatic and medicinal; good to expel wind, warm and comfort the ſtomach; but the ſeeds are rather the moſt material part.

[2]LIGUSTICUM *Scothicum.*

*Scottiſh Lovage.*] Hath a thickiſh, fleſhy, penetrating, perennial root; crowned by large doubly-trifoliate leaves, with broad, ſhort, indented lobes; upright, round ſtalks, half a yard high; terminated by ſmalliſh yellow umbels.

Both theſe ſpecies flower in June and July, and ripen plenty of ſeeds in autumn.

They are hardy plants, durable in root, but annual in leaf and ſtalk, though the ſecond ſort is alſo ſometimes biennial; both ſorts

ſorts may eaſily be raiſed from ſeed, and freſh plants from ſcattered ſeeds, will riſe ſpontaneouſly.

Both the ſorts may be admitted into large pleaſure-grounds, to encreaſe the variety of herbaceous perennials, and the firſt ſort alſo for medicine, and will proſper in any common ſoil and ſituation.

Their propagation is by ſeed in autumn or early in ſpring: ſow it in any bed or border broad-caſt, and rake it in. When the plants are three or four inches high, plant them out into beds of moiſt earth, two feet aſunder, and in autumn, thoſe intended for the pleaſure-ground ſhould be tranſplanted therein, but let thoſe for medical uſe remain in the beds.

LIGUSTRUM, Privet.

This genus furniſhes a hardy, deciduous, and ever-green ſhrub for the ſhrubbery; both varieties of one ſpecies, adorned with oblong entire leaves, and ſpikes of infundibuliforme white flowers, ſucceeded by black berries.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is monophyllous, tubular, and four-parted at top. COROLLA, is monopetalous, funnel-ſhaped, with a cylindric tube, cut at top into four oval ſegments. STAMINA, two filaments, and erect antheræ the length of the corolla. PISTILLUM, a roundiſh germen, ſhort ſtyle, and obtuſe bifid ſtigma. PERICARPIUM, a roundiſh ſmooth unilocular berry, having four ſeeds.

Modern botaniſts admit but of one ſpecies, the principal of which is deciduous, and the variety an ever-green.

'LIGUSTRUM *Vulgare.*

*Common Privet*;——Conſiſts of the two following varieties:

*Deciduous Privet.*] Hath a ſhrubby ſtem, branching erectly ten or twelve feet high, the branches numerous quite from the bottom, ſlender, pliable, and tough; ſpear-ſhaped-oval, oppoſite, cloſe ſitting, deciduous leaves, two or three inches long; and white flowers in thick erect ſpikes at the ends of the branches, ſucceeded by cluſters of black berries.

*Ever-green Privet.*] Hath a ſhrubby, ſtronger upright ſtem, branching more erectly, twelve or fifteen feet, having numerous branches quite from the bottom, of a pliable tough nature; ſpear-ſhaped, acute, oppoſite, dark ever-green leaves, about three inches long, and half as broad; and white flowers, in erect ſpikes at the ends of the branches, ſucceeded by bunches of black berries.

Both theſe ſhrubs flower in May and June, the flowers make a tolerable appearance, and are ſucceeded by the berries, furniſhing ripe ſeed in autumn, and frequently remain on the plants the greateſt part of winter.

The flowers are of one funnel-ſhaped petal, ſeparately ſmall, but being collected into cloſe ſpikes, are very conſpicuous.

Both the varieties of theſe ſhrubs are very hardy, durable in root, ſtem, and branches, which are able to reſiſt the ſevereſt cold with impunity, and as they branch numerouſly all the way from the bottom, cloſely garniſhed with leaves, and their berries remaining ſingularly ornamental great part of winter, renders them proper furniture for ornamenting the common ſhrubbery-compartments in aſſemblage; but the ever-green kind has the greateſt claim to eſteem, though both ſorts merit admittance in the ſhrubbery collection, to encreaſe the variety; hardly any ſituation or ſoil comes amiſs to them, either in open or ſhady places, even under the ſhade of other trees; and in the midſt of great towns and cities, particularly the deciduous kinds, as is evident in London, where vaſt quantities are brought to the markets, and hawked about the ſtreets, which are ready ſale, for the inhabitants to ornament their ſmall gardens, courts, and balconies.

Theſe ſhrubs are alſo often employed to form hedges in gardens, for which purpoſe, as they are cloſely branched to the very bottom, and thickly ſet with leaves, they are tolerably well adapted, and may be made to form a cloſe handſome hedge; but would adviſe the ever-green kind to be principally choſen for this uſe. See HEDGES.

The propagation of both ſorts is by ſeed, ſuckers, layers, and by cuttings; all in the open ground.

By Seed.—Sow the ſeed in October, November, or December, in a bed of common earth, an inch deep, or in drills that depth; or, as they do not grow the firſt year, they may be buried till next autumn, in pots in the ground, as practiſed for haws, and then ſowed as above. When the plants come up keep them hand-weeded, and when a year or two old, plant them out in nurſery rows to remain two or three years, then tranſplanted for good where wanted.

By Suckers.—Great plenty of ſuckers riſe annually from the roots, which may be taken up in autumn, winter, or ſpring, with roots, and planted in the nurſery as above.

By Layers.—Lay down ſome of the pliable young branches in the earth, in autumn or winter, and they will be well rooted by autumn following; then cut them from the ſtool, with their roots, and plant them in the nurſery for two or three years.

By Cuttings.—In autumn plant cuttings of the young ſhoots, eight or ten inches long, in a ſhady border, they will be properly rooted by next autumn, then plant them out in nurſery rows, to remain till winter.

LILIACEÆ, *Liliaceous Plants*, plants whoſe flowers reſemble thoſe of a lily.

Liliaceous plants are ſuch as have ſix regular petals, in the form of a lily; or three, or even one petal deeply divided into ſix ſegments, and aſſume a lily-flower form; all Liliaceous plants, however, have not flowers ſo large as the *Lilium*, ſome being conſiderably ſmaller.

As the *lilium*, or common lily, have no calix, ſeveral of the Liliaceous flowers are alſo deſtitute of a cup; and ſeveral have cups, which are all principally of that ſort of cup called a ſpatha.

The following are the principal Liliaceous plants, diſtinguiſhing thoſe without, and thoſe with cups, or ſpathas.

Without Cups.—*Lilium*, or common lily, all the ſorts—tulip, all the kinds—fritillary, and crown imperial—hyacinth—ſtar of Bethlehem—baſtard ſtar of Bethlehem—tuberoſe—aſphodelus—ſquill—hemerocallis, or day-lily—anthericum, or ſpiderwort—aloe—yucca, or Adam's needle—glorioſa, or ſuperb lily.

With Spathas, or Cups.—crocus—galanthus, or common ſnow-drop—leucojum, or great ſnow-drop—daffodil, narciſſus, and jonquil—crinum, or aſphodel lily—colchicum—iris, or flower-de-luce—hæmanthus, or blood-flower—gladiolus, or ſword-lily—Virginia ſpider-wort—amaryllis, including the Guernſey lily, belladenna lily, and Jacobæa lily, &c.—pancratium lily.

The greater part of all theſe Liliaceous plants of both claſſes are bulbous-rooted; ſome, however, have tuberous, and ſome fibrous roots; and all of them perennial in root, but annual in ſtalk.

They all produce ornamental garden-flowers, and moſt of them hardy enough to grow in the open ground; ſome for the green-houſe and ſtove.

The culture of each ſort, &c. is fully directed in their proper genera.

LILIUM, Lily.

This genus furniſhes a beautiful collection of bulbous-rooted, herbaceous, flowery perennials, of majeſtic growth, all proper for ornamenting the pleaſure-garden; riſing with erect annual ſtalks, three or four feet high, garniſhed with long narrow leaves, and terminated by noble cluſters of large, bell-ſhaped, hexapetalous flowers, of exceeding beauty.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, is large, bell-ſhaped, and of ſix long petals, narrow at the baſe, but widening gradually upward, in ſome ſorts erect, in others turned quite back, each of thick ſubſtance, keel-formed on the back, and a nectarium forming a longitudinal line behind near the baſe. STAMINA, ſix long ſubulate filaments, and oblong incumbent antheræ. PISTILLUM, an oblong cylindric, ſix-furrowed germen, and a cylindric ſtyle the length of the corolla, and a thick triangular ſtigma. PERICARPIUM, an oblong ſix-furrowed, trivalvular, trilocular capſule, filled with ſemi orbicular ſeeds lying over each other, in a double order.

This genus retains all the varieties of White Lily—Orange Lily—and Martagon Lily; this latter is very diſtinguiſhable from the two former, by having the petals of the corolla, revolute, or rolled back; but ſee each under its diſtinct head.

### *White Lily Kinds.*

Of theſe kinds there is only one ſpecies, but which comprehends ſeveral beautiful varieties, and the common White Lily, found in moſt gardens, is parent of them all, and all of which have large, white, ſcaley, bulbous, perennial roots, crowned with leaves from autumn till ſummer, and ſends up flower-ſtalks annually, terminated by the flowers, which in all the varieties are pure white, tho' with ſome variations.

LILIUM *Candidum.*

*White Lily*; of which there are the following varieties.

*Common White Lily.*] Hath a large ſquamous, bulbous root; crowned by a cluſter of long

long broad leaves, close to the ground, remaining all winter and spring; amidst them an upright firm flower-stalk, a yard or more high, garnished with many narrow leaves placed irregularly; and terminated by a long cluster of large open bell-shaped, pure white flowers, one above another, having the inside of the petals smooth.

*Varieties of this are*] Common white Lily with striped leaves——with purple-striped flowers—double-flowered.

The two following are also supposed to be varieties only of the common white Lily, differing from it principally in that the above kinds have generally erect flowers, and these have dependent or drooping flowers, and some other variations, as in their descriptions, viz.

*Dependent White Lily of Constantinople.*] Hath a large scaley bulbous root; with leaves and flower-stalks like the parent sort, only the stalk is more slender, the flowers smaller, and generally growing in a dependent or drooping position.

*Dependent, broad-stalked, most-floriferous white Lily of Constantinople.*] Hath a bulbous root, and leaves like the other; but the stalk large, broad, and flat, sustaining at top, a large bunch of pendent flowers, from fifty or sixty to a hundred in number.

All the above varieties are by modern botanists arranged as varieties only of the *Lilium Candidum*, or common white Lily, obtained by the effects of culture; and that by continuing to encrease them by off-sets of the root, they will all retain their differences; and by seed more varieties may be gained.

They have all great merit in the beauty of their flowers, which have also great fragrance, particularly all the single-flowered kinds; but the double sort having often such a multiplicity of petals as to exclude the stamina and antheræ, the parts from which the effluvia proceeds, that they are frequently destitute of fragrance. All the sorts, however, demand attention as flowery plants, and are all so exceeding hardy as to prosper in almost any soil and situation without trouble; and if intermixed with each other, and the other species of this genus, they will exhibit a delightful variety, in the beauty of their elegant flowers; and the striped-leaved variety merits double esteem, for being not only ornamental in its flowers, like the others, has great singularity in its finely-striped leaves which being long, broad, and elegantly striped with yellow, spreading all around flat on the ground, and abiding, appear exceedingly ornamental, but more conspicuously so in winter and early spring.

They all flower in June and July, and their stalks decay in August, when the roots remaining for some little time at rest, is the only proper period for taking up the bulbs, when necessary, as hereafter observed.

### *Orange-Lily Kind.*

This furnishes only one species, but which, like the former, is prolific in some eminent varieties; all with large, roundish, scaley, bulbous, perennial roots; crowned with leaves in spring that decay in autumn and winter; and annual flower-stalks terminated by the flowers, which are universally of a reddish, or orange-colour, some more fiery than others.

[2]LILIUM *Bulbiferum.*

*Bulbiferous, or Bulb-bearing Lily.*—Of which there are the following varieties:

*Common Orange Lily.*] Hath a large squamous bulbous root; an upright firm flower-stalk, rising three feet high; very closely garnished with oblong, narrow, rigid, dark, shining leaves, placed irregularly; and the top crowned by a cluster of large, open, bell-shaped, erect-growing, orange-coloured flowers, rough within.

*Varieties of this*] With double flowers—with variegated leaves—dwarf-stalked.

All these sorts flower in June and July very conspicuously, and their stalks decay in August or September, when their roots remain at rest for two months, which is the time for removing them, when necessary, either to separate the off-sets, or transplant the main roots from one place to another.

They are all very hardy, and will thrive almost any where, no soil comes amiss to them, and grow freely either in open situations, or under shade of trees, or in towns among buildings, &c.

The stalks of these sorts remain fully adorned with leaves till the decay of the flowers, &c.

*Bulbiferous Fiery Lily.*] Hath a scaley bulbous root; an upright firm flower-stalk, half a yard or two feet high; garnished with narrow leaves, placed scattering; and bearing bulbs at the joints; and terminated by smaller upright, bright flame-coloured flowers.

*Varieties of this*] Greater broad-leaved bulbiferous Lily—many-flowered bulbiferous Lily—ſmall bulbiferous Lily—hoary bulbiferous Lily.

All theſe bulbiferous kinds flower ornamentally in May and June, at which time all the ſorts bear many ſmall bulbs on their flower-ſtalks, which are embryo plants, and if taken off when the ſtalks decay, and planted in any bed or border, they will readily grow, and flower the ſecond year. All the ſorts, however, encreaſe alſo abundantly by off-ſets of the root, and may be taken off in autumn, as obſerved above for the Orange Lilies.

Theſe ſorts are alſo all as hardy as the Orange Lilies, and will grow in any ſoil and ſituation.

*Martagon Kinds.*

There are ſeveral ſpecies, all of which differ from the white and orange Lily kinds, in having the flowers reflexed, and the petals of the corolla revolute, or rolled quite back; they have all large, ſcaley, bulbous, perennial roots; leaves and flower-ſtalks riſing annually in ſpring, ſurmounted by many flowers, generally in a reflexed or drooping poſition, and with all their petals turned back toward the ſtalk.

[3]LILIUM *Martagon.*

*Old Purple Martagon, or Turk's Cap.*] Hath a large ſquamous bulbous root; upright flower-ſtalk, three or four feet high, garniſhed with broadiſh leaves, in whorls, and terminated by large looſe ſpikes of purpliſh, black-ſpotted, reflexed flowers, with revolute petals.

*Varieties.*] Double flowered old Martagon—red old Martagon, with hairy ſtalks—imperial old Martagon, with divided ſtalks.

This ſpecies and varieties have been long inhabitants of our gardens; they all flower in June, have a good appearance, but impart a diſagreeable odour.

[4]LILIUM *Pomponium.*

*Pomponey Martagon.*] Hath a large ſcaley bulbous root; an upright flower-ſtalk, three or four feet high; garniſhed with narrow awl-ſhaped leaves, placed ſparſedly; and the top terminated by many reflexed, bright-red flowers, having revolute petals.

*Varieties.*] Pomponey double red Martagon—white pomponey Martagon——double white Martagon—red ſpotted Martagon——white-ſpotted pomponey Martagon—yellow pomponey Martagon—yellow-ſpotted pomponey Martagon—early ſcarlet Martagon—major ſcarlet pomponey Martagon.

All theſe pomponey Martagons flower in June, and make a fine appearance, their flowers being large and numerous.

They are hardy, grow freely any where, and may be propagated plentifully by off-ſets when their ſtalks decay.

[5]LILIUM *Chalcedonicum.*

*Chalcedonian Scarlet Martagon.*] Hath a large bulbous root; an upright thick flower-ſtalk, three feet high; cloſely garniſhed with broad ſpear-ſhaped leaves, placed irregularly; and terminated by ſeveral large, reflexed, bright-ſcarlet flowers, with revolute petals.

*Varieties.*] With deep-ſcarlet flowers——with purple flowers—with large bunches of flowers.

They all flower in July, and make a very fine appearance; will grow any where, and multiply faſt by off-ſets of the root.

[6]LILIUM *Superbum.*

*Superb Great Yellow Martagon.*] Hath a large, ſcaley, bulbous root; ſtrong upright ſtalk, four or five feet high; garniſhed with broad, ſpear-ſhaped, ſparſed leaves; and terminated by numerous, large, reflexed, revolute, yellow flowers, in a pyramidal cluſter; flowers in June or July.

This makes a noble appearance, and is worthy of a place in every collection.

[7]LILIUM *Canadenſe.*

*Canada Spotted Martagon.*] Hath a large ſcaley bulbous root; an upright ſtrong ſtalk, riſing four or five feet high; garniſhed with oblong pointed leaves, in whorls; and terminated by numerous, large, bell-ſhaped, reflexed, yellow flowers, ſpotted with black, having the petals ſcarcely revolute.

This flowers in Auguſt, is a fine majeſtic plant, and makes a grand appearance during the time of its blow.

*Variety*] With deep yellow flowers.

All theſe ſeven ſpecies of *Lilium*, and reſpective varieties, are univerſally bulbous in root, as before obſerved, very large, compoſed of numerous ſquamæ, or ſcales, encreaſe conſiderably by off-ſets, and are all perennials; but are annual in ſtalk, which always riſe directly from the root in ſpring, crowned immediately with the flower buds, which in all the ſorts, ſtand naked without any ſort of calix or cup; each flower is large and of ſix oblong petals, blowing in perfection principally in June, July, and Auguſt, ſucceeded

ceeded by ſeed in autumn; then the ſtalks decay, and the roots ceaſe to grow for ſome ſpace of time that ſeaſon; which period of reſt, before the bulbs begin again to grow, is the proper time to remove them, when neceſſary, either to ſeparate the off-ſets for encreaſe, or to tranſplant the main roots into another place, or to take them up for ſale, &c.

They all demand eſteem as plants of ornament for the beauty of their flowers, which are ſtrictly noble, and ſome of the grandeſt that adorn our gardens, though on account of their commonneſs and eaſy culture, are rather diſregarded; but even the moſt common ſorts of them claim attention as flowery plants, as for inſtance, the white Lily, very common in moſt places, is nevertheleſs a very elegant flower, it adorning the top of the ſtalk in a vaſt cluſter of pure ſnowy white flowers, that whereſoever ſituated, it diſtinguiſhes itſelf ſingularly ornamental, and diffuſes a fragrant odour all around. All the others poſſeſſes alſo a proportionable degree of beauty and value for the embelliſhment of the pleaſure ground. Therefore all the ſpecies and reſpective varieties, are proper ornaments for every compartment of the pleaſure-ground; and if the different ſorts are properly intermixed, they will effect a moſt elegant variety, ſucceeding each other in blow, upwards of three months; obſerving if any ſorts are wanted particularly for ſhady or cloſe places, the common white Lily, orange Lily, and common Martagons, are the moſt eligible, for they will thrive under trees; and the orange Lily alſo often in ſmall gardens in the midſt of buildings, in towns and cities; but beſides planting all the ſorts for the beauty of their flowers, I would adviſe to have many of the ſtriped-leaved white Lily placed towards the fronts of the moſt conſpicuous compartments, for the beauty alſo of its leaves in autumn, winter, and ſpring, as already obſerved, which, if diſpoſed alternately with the common white Lily, whoſe leaves are entirely green, they will exhibit the more ſtriking variety.

One method of planting and general culture is the ſame for all the ſorts.

The proper time for planting and tranſplanting them is in autumn, when their flowers and ſtalks decay, which is generally in Auguſt and September, the roots being then at reſt for a ſhort ſpace of time, which is the only proper ſeaſon for removing them, and for procuring roots to plant; though the bulbs taken up at the above ſeaſon of reſt, may be kept out of ground, if neceſſary, till October or November: the white Lilies, however, do not ſucceed if kept long out of the earth, and all the others ſucceed beſt when planted again as ſoon as poſſible. The bulbs of all the ſorts are ſold at the nurſeries; their prices are very reaſonable, and the moſt proper time to apply for them is from the end of Auguſt till October, as above noticed.

Plant them ſingly in different parts of the the borders, and towards the front of the principal ſhrubbery clumps; placing them four or five inches deep, and at good diſtances from one another, obſerving to mix the different ſorts in the alternate way; that is, plant firſt a white, next an orange Lily, &c. ſtationing ſome forward, others more back in the ſeveral compartments to effect the greater ſhow of variety.

After being planted, none of the ſorts require any particular culture, for they will endure all weather at every ſeaſon; ſo no more is neceſſary than deſtroying weeds among them by hoe, and as ſome of them run up with pretty tall ſlender ſtalks, they, if ſupported with ſticks to preſerve effectually their upright poſition, their flowers will always appear to the beſt advantage.

They may all remain undiſturbed two or three years, or longer, nor indeed is it proper to remove theſe ſorts of bulbs oftener, for by remaining they flower ſtronger after the firſt year, and having encreaſed by off-ſets into large bunches, many ſtalks will riſe from each bunch of roots, ſo as to exhibit a large cluſter of flowers; it is, however, proper to take up the bulbs entirely every three or four years at leaſt, at the decay of the ſtalk, to ſeparate the encreaſed off-ſets both for propagation, and to diſburthen the main roots, and give them room to take their proper growth.

Obſerve, that when deſigned to remove any of theſe kinds of bulbs, the proper ſeaſon for it is in ſummer and autumn, July, Auguſt, and September, when their flower-ſtalks decay, and the bulbs done growing, before they begin again to emit freſh fibres below, and to form any ſhoot at top, after which effort of growth, it is improper to remove them that ſeaſon, which would prevent their flowering the following year, and ſome ſorts probably

Probably not the year after in due perfection, for it weakens thoſe large kinds of bulbs conſiderably when removed at an improper ſeaſon; mark, therefore, the above mentioned time for removing the roots of all theſe ſpecies; for when having done their year's growth, at the decay of the flower and ſtalk, they become inactive for ſome time, not drawing any nouriſhment, and at which period they may be ſafely removed; but as ſome ſorts very ſoon begin again to emit new fibres at bottom, and form the ſhoot of the future leaves and flowers, which is particularly the caſe of all the white Lily tribe; ſo that when neceſſary to remove the roots, obſerve the proper time, as above, and never remove any of the ſorts after they have begun to ſhoot again, if you would inſure the next year's bloom and proſperity of the bulbs. I would, however, remark, that as ſome ſorts, ſuch as the orange Lily kinds, &c. do not begin to puſh new leaves till towards ſpring, the roots may more ſafely be removed, if neceſſary, any time from the decay of the flower and ſtalk, till toward Chriſtmas: but would obſerve on the other hand, that the ſooner the removal or planting is performed after the decay of the ſtalk, the better; for all bulbs planted early in autumn, flower ſtronger than ſuch as are planted a month or two later. See BULBUS.

Such bulbs, however, which are removed at the proper period of reſt may, if occaſion require it, be kept out of ground a month or two, eſpecially in dry ſand or moſs, or the like, to keep them from drying and ſhrinking by the air; but the retention of theſe roots long out of the earth, ſhould only be practiſed, either when neceſſary to keep them for ſale, or to ſend to any diſtance, or that the ground is not ready for their reception, and ſuch like occaſions; though they ſhould never be kept out of ground longer than October, or November at lateſt; the white Lily kinds in particular, ſhould be kept but as ſhort a time as poſſible above ground.

*Propagation of all the Sorts.*

The propagation of all the ſorts is moſt commonly by off-ſets of the root; they may alſo be raiſed from ſeed to obtain new varieties.

By Off-ſets.—All the ſorts of theſe roots yield off-ſets abundantly every year, which when greatly wanted for propagation, may be taken off annually in autumn, otherwiſe once in two or three years, according as they are wanted; and the proper time of the year is in ſummer and autumn, when the flower is paſt and the ſtalks decayed, as obſerved above; obſerving, that in order to ſeparate the off-ſets properly, the whole ſhould be taken up, and all the off-ſets, ſmall and great, ſeparated from the main bulbs: the ſmall off-ſets ſhould then be planted in beds a foot aſunder, and three deep, to remain a year or two; and the large bulbs ſhould be planted again in the borders, &c. ſingly; the off-ſets alſo in the nurſery beds, after having obtained ſize and ſtrength for flowering in perfection, may be planted out where wanted.

By Seed.——This is ſometimes practiſed, but more particularly for the Martagons, to obtain more varieties. In autumn, ſoon after the ſeed is ripe, ſow it in pots or boxes of rich light earth, half an inch deep; place the pots in a ſheltered ſituation all winter, and the plants will appear in the ſpring; when in April remove the pots to have only the morning ſun all the ſummer, giving moderate waterings; in Auguſt tranſplant the bulbs into nurſery-beds in flat drills an inch deep, and three or four aſunder, but as the bulbs will be very ſmall, ſcatter the earth and bulbs together in the drills, and cover them with earth the above depth; and having growed here till Auguſt or September following, tranſplant into another bed, placing them eight or nine inches each way aſunder, here to remain to ſhow their firſt flowers, then tranſplant them finally into the pleaſure-ground.

LINUM, Lint, or Flax.

This genus conſiſts of herbaceous annuals and perennials of erect growth, proper both for valuable oeconomical uſes, and to form variety in gardens. The common flax being a moſt valuable annual for field culture, for the bark of its ſtalks to make linen, and its ſeeds linſeed-oil; and ſome of the perennials ſerve to adorn the pleaſure-ground; all of them riſing with erect ſtalks from about two to four or five feet high, garniſhed with narrow leaves, and terminated by ſmall funnel-ſhaped quinquepetalous flowers.

Claſs and order, *Pentandria Pentagynia.*

*Characters.*] CALIX, five ſpear-ſhaped permanent leaves. COROLLA, is funnel-ſhaped, conſiſting of five oblong petals. STAMINA, five awl-ſhaped filaments, and arrow-ſhaped antheræ. PISTILLUM, an oval germen, five filiforme ſtyles, and reflexed ſtigmas.

ſtigmas. PERICARPIUM, a globular, pentagonous, quinquevalvular, decemlocular capſule, having one oval plane ſeed in each cell.

There are many ſpecies, but not more than one proper for oeconomical uſes, which is the common Flax, an annual; and one ſometimes cultured in gardens for variety, a perennial.

1 LINUM *Uſitatiſſimum.*

*Moſt Uſeful, or Common Cultivated Annual Flax.*] Hath a taper fibrey root; upright, ſlender, unbranched ſtalk, two feet and a half high; garniſhed with narrow, ſpear-ſhaped, alternate, grey coloured leaves; and the ſtalk dividing into foot-ſtalks at top, terminated by ſmall, blue, crenated flowers, in June and July; ſucceeded by large round capſules of ten cells, containing each one ſeed.

This may be ſaid to be one of the moſt valuable plants in the whole vegetable kingdom; as from the bark of its ſtalks is manufactured the Flax, or Lint, for making all ſorts of linen cloth; from the rags of the linen is made paper; and from the ſeeds of the plant is expreſſed the linſeed oil, ſo uſeful to phyſicians as well as painters, and other trades.

The plant is annual, and is raiſed in fields like corn. See its *Culture.*

2 LINUM *Perenne.*

*Perennial Siberian Flax.*] Hath a fibrated perennial root, ſending up annually ſeveral upright annual ſtrong ſtalks, branching four or five feet high; garniſhed with ſmall, narrow, ſpear-ſhaped, alternate, dark-green leaves; and terminated by umbellate cluſters of large blue flowers in June, ſucceeded by ſeeds in autumn.

Both theſe ſpecies of *Linum* are hardy, the firſt is but of one year's duration, the ſecond of many by the root, but is annual in ſtalk.

The firſt is cultivated in fields for the uſes before obſerved, but rarely in gardens, except a few plants in patches for variety; it riſes from ſeed in ſpring, ſhoots up into ſtalk gradually arriving to its full height in June and July, and having ſtood to perfect its ſeed, is then pulled and prepared for uſe.

The perennial ſort is proper furniture for any of the large borders, or other parts of the pleaſure garden to encreaſe the variety.

*Propagation of both Sorts.*

The propagation of both theſe plants is by ſeed in ſpring; the common ſort is ſowed in fields, as hereafter directed; and the perennial ſort in a bed or border of common garden-earth, in ſhallow drills ſix inches aſunder; and when the plants are two or three inches high, thin them to the ſame diſtance, and in autumn may plant them out where wanted, where they will abide by the roots many years, producing new ſtalks every ſpring.

But with reſpect to the general culture of the common Flax, this is raiſed in great quantities in fields in many places, both for the ſake of its ſtalks to afford the flax for linen, and its ſeeds for oil, as above noticed.

It ſhould have as good ground as poſſible, and this prepared for the reception of the ſeed, by proper repeated ploughings, and harrowings, to render the ſoil fine, and the ſurface even; and March and beginning of April is the ſeaſon for ſowing it: about two buſhels is the proper quantity for an acre. It may be ſowed either broad-caſt, and harrowed in with a light harrow, or may be ſowed in ſhallow drills eight or ten inches aſunder, though the former is the moſt expeditious method; but by having it in drills, the ground can be readily hoed to deſtroy weeds, and which by looſening the ground, will prove alſo very beneficial to the crop of Fax, nor will the plants be liable to be trodden down as when they grow promiſcuouſly.

Weeds, however, muſt at any rate be kept down, either by repeated hand-weedings, or by hoeing, as ſhall be convenient, which ſhould be ſtrictly attended to while the plants are young, and until they are grown above the reach of the weeds.

In the middle or latter end of Auguſt, the plants will be arrived at full growth, begin to turn yellow at bottom, and brown at top, and their ſeeds ripen, it is then the proper time to pull them, though if it was not for the ſake of the ſeed, they might be pulled a little before the ſeeds ripen, whereby the Flax is generally better coloured and finer; but if ſuffered to ſtand till the ſeeds are fully ripe, it is commonly ſtronger, ſomewhat coarſer and more in quantity. It ſhould be pulled up by handfulls, roots and all, ſhaking off all the mould; then either ſpread them on the ground by handfuls, or bind them in ſmall bunches, and ſet them upright againſt one another, for ten days or a fortnight, till they are perfectly dry and the ſeed ripened; then ſhould be houſed, and the ſeeds threſhed out; winnowed and properly dried in an airy room, and then put up for uſe; the flax ſhould then be rippled and ſorted, and afterwards carried

to

to a pond or canal of water, and laid to ſteep, covering it down with ſtraw hurdles, or the like, laying ſtones on them; and are to remain till the ſtalks become brittle, and the bark or rind, the uſeful part, ſeparate readily from the reed; it is then properly ſteeped, when it muſt be taken out and ſpread by handfulls in ſwaths to dry, turning it occaſionally till properly bleached and dried, and it is then ready for the flax dreſſer.

LIQUIDAMBAR, Sweet Gum-tree.

This genus furniſhes two beautiful deciduous trees for ornamental plantations, growing thirty or forty feet high, forming fine pyramidal heads, adorned with large angular and oblong leaves, and monoecious apetalous flowers.

Claſs and order, *Monoecia Polyandria.*

*Characters.*] CALIX, male and female apetalous flowers, apart on the ſame tree, the males numerous in conical looſe catkins, and females in a globe, at the baſe of the male ſpike; the males having a four-leaved involucrum, which in the females is double; and each floret a bell-ſhaped proper cup. COROLLA, both male and female florets are apetalous. STAMINA, numerous ſhort filaments, incorporated in a body; and didymous, four-furrowed, bilocular, erect antheræ. PISTILLUM, an oblong germen, two ſubulate ſtyles, and recurved downy ſtigmas. PERICARPIUM, many unilocular, bivalvular capſules, collected into a globular ligneous body, having many oblong ſeeds.

There are but two ſpecies, both of America, but very hardy trees, of the deciduous tribe, and are ſingular for producing a liquid, tranſparent, gummy ſubſtance of great fragrance.

1 LIQUIDAMBAR *Styraciflua.*

*Styraciflua, or Maple-leaved Virginia Liquidambar.*] Riſes with an upright ſtraight ſtem, and regular branchy head, thirty or forty feet high; palmated-angulated leaves, of five ſerrated lobes; exſuding a glutinous fragrant ſubſtance; and ſaffron-coloured flowers in amentums at the ends of the branches in April; ſucceeded by large roundiſh fruit, having many protuberances.

2 LIQUIDAMBAR *Aſplenifolia.*

*Spleenwort-leaved Canada Liquidambar.*] Riſes with an upright ſtem, branching twenty or thirty feet high; oblong leaves, ſinuated on the edge alternately very deep; and ſaffron-coloured flowers in amentums, ſucceeded by roundiſh fruit.

Both theſe trees have great merit for the embelliſhment of the ſhrubbery plantations, in aſſemblage with others of the deciduous tribe of ſimilar growth; and being handſome ſtraight-growing trees, forming fine heads, attaining their proper height in this country, are alſo well adapted for planting detached as ſingle objects in ſpacious graſs opens to diſplay their fine pyramidal growth; in which they will appear very ornamental, and by emitting their odoriferous particles, will perfume the circumambient air in ſummer.

They proſper in any common ſoil and ſituation, and endure our ſevereſt cold without injury.

Both the ſorts are retained in the nurſeries for ſale, but the firſt is the moſt common.

Their propagation is by ſeed, and by layers, in the full ground.

By Seed.—The ſeed arrives from America in ſpring, when it ſhould be ſowed as ſoon after as poſſible, in a bed of light earth, half an inch deep, and the plants will riſe ſome the ſame year, others probably not till the ſpring following; indulge them with moderate waterings occaſionally; keep them clean from weeds all ſummer, and give protection from ſevere froſt, the firſt two winters; and when two years old, plant them out in ſpring in nurſery rows, two feet aſunder, to remain three or four years, or till wanted for the ſhrubbery, &c.

But ſome perſons ſow the ſeeds in pots, &c. in order to move to different ſituations as the ſeaſon requires; and that if the plants ſhould not come up the ſame year, the pots may be plunged in a hot-bed the ſpring following to forward them.

By Layers —— In autumn lay the young ſhoots of the preceding ſummer, by ſlit-laying, &c. and they will moſt of them be rooted by autumn following, though in a dry hungry ſoil they are ſometimes two years before they are ſufficiently rooted for tranſplantation.

LIRIODENDRON, Tulip-tree *(Tulipifera).*

One large hardy deciduous tree, of North America, for ornamental plantations, conſtitute this genus, adorned with large, broad, lobated leaves, and hexapetalous liliaceous flowers, fancied to reſemble the form of a tulip; hence the name Tulip-tree.

Claſs and order, *Polyandria Polygamia.*

*Characters.*]

*Characters.*] CALIX, a two-leaved involucrum, and three-leaved inner cup, all deciduous. COROLLA, is bell-ſhaped, and conſiſts of ſix petals, in two ſeries, obtuſe and channelled at the baſe, the outer three are deciduous. STAMINA, numerous linear filaments, having narrow antheræ faſtened longitudinally to their ſides. PISTILLUM, numerous germina formed into a cone, no ſtyle, but a globular ſtigma crowning each germen. PERICARPIUM, none, numerous ſeeds collected imbricatumwiſe into a ſort of cone.

There is but one known ſpecies, which formerly was termed *Tulipifera*; but is now changed by Linnæus to *Liriodendron*, from the fancied reſemblance of its flower to a lily, whence it might with as much or more propriety be called Lily-tree as Tulip-tree.

LIRIODENDRON *Tulipifera*.

*Tulip-tree.*] Riſes with an upright large trunk, branching irregularly forty or fifty feet high; large lobated alternate leaves, of three lobes, the middle one truncated, thoſe of the ſides rounded; and from the ends of the branches bell ſhaped flowers, compoſed of ſix petals in a double ſeries, ſpotted with green, red, white, and yellow; appearing ornamentally in July, ſucceeded by large conic fruit, not ripening in England.

Some of theſe trees have acquired a large ſize and ſtature in England, and produce flowers, which they never effect till of ſome conſiderable age and bulk; the trunk is covered with a grey bark, and the younger wood of a blueiſh or browniſh colour, commonly very pithy, and when broken, emits a ſtrong aromatic odour, and the leaves are of ſingular ſtructure on long foot-ſtalks. In America ſome of theſe trees are thirty feet in circumference, with large very unequal and irregular boughs; and the timber is of great uſe in its native ſoil, particularly for making that kind of boat called periaugues, which are formed of the trunk, excavated or hollowed.

This curious tree grows freely here in the full ground, and is proper for our ornamental plantations, ſtationing them with the deciduous kinds of ſimilar growth; is alſo very proper to exhibit ſingly in large lawns and other ſpacious opens of graſs-ground.

It is cultivated for ſale in all the nurſeries.

Its propagation is by ſeed.—This is imported annually from America, which may be had of the ſeed-dealers in ſpring; and is then to be ſowed in the full ground, in beds of light earth, placing the ſeed length-wiſe, and cover it near an inch deep; they will come up the ſame year in May; obſerving to give water in dry weather, and if the bed is arched over with hoops, to have occaſional ſhade from the mid-day ſun in ſcorching weather, it will prove very beneficial to the germination of the ſeeds, and growth of the young plants, being alſo careful to continue the waterings occaſionally during the ſummer; and in the winter, if you allow them ſhelter of mats in froſty weather, it will effectually preſerve their tops, which being ſometimes a little tender the firſt year, are apt to ſuffer by froſt; however this covering is not always abſolutely neceſſary, for I have obſerved them ſtand very well without any. When they are two years old, plant them out in ſpring in nurſery-rows, two feet diſtant, and a foot aſunder in each row; there to remain a few years, till from three to ſix or eight feet high, then tranſplanted where they are always to ſtand.

LOBELIA, Cardinal-flower *(Repuntium.)*

It conſiſts of herbaceous and underſhrubby erect flowery perennials for the pleaſure-garden and hot-houſe, riſing with erect ſtalks from about two to five or ſix feet high, ornamented with oblong, oval, and ſpear-ſhaped, ſimple leaves; and ornamental ſpikes of beautiful, monopetalous, ſomewhat ringent, five-parted flowers.

Claſs and order, *Syngeneſia Monogamia.*

*Characters.*] CALIX, is ſmall, monophyllous, quinquedented, and growing round the germen. COROLLA, is monopetalous, a little ringent, and with a long cylindric tube, and five-parted limb, the two upper parts ſmalleſt, and form the upper lip, and the other largeſt and ſpreading. STAMINA, five ſubulate filaments, having ſyngeneſious antheræ. PISTILLUM, an acuminated germen under the corolla, cylindric ſtyle, and obtuſe hairy ſtigma. PERICARPIUM, an oval bilocular capſule, opening at top, and numerous ſmall ſeeds.

There are many ſpecies, but not more than three or four commonly cultivated, two hardy herbaceous kinds for the open ground, and two ſhrubby plants for the ſtove.

*Hardy Herbaceous Kinds.*

Theſe are fibrous-rooted, erect-growing perennials, natives of North America, but

have been long retained in the Engliſh gardens for the beauty of their flowers.

[1]LOBELIA *Cardinalis.*

*Common Cardinal Flower.*] Hath a thick, fibrated, milky, perennial root; crowned with lanceolate, ſerrated, radical leaves; upright, firm, round ſtalks, riſing two feet high; garniſhed with ſpear-ſhaped, ſawed, alternate leaves; and terminated by long ſpikes of beautiful ſcarlet flowers, in July and Auguſt.

[2]LOBELIA *Siphilitica.*

*Siphilitic Blue Cardinal Flower.*] Hath a thick, fibrated, perennial root; crowned with oval, lanceolate, crenated, radical leaves; upright firm ſtalks, half a yard high; garniſhed with leaves like the radical ones; and from the axillas, pale-blue flowers, with reflexed cups; appearing in July.

*Varieties.*] With deep-blue flowers—violet-coloured flowers.

Both theſe ſpecies flower very ornamentally, and the flowers numerous in long ſpikes; which in dry warm ſeaſons, are ſucceeded here by ripe ſeeds in autumn.

They are hardy enough to ſucceed in the full ground all the year in a dry warm ſoil, though as being liable to ſuffer by ſevere froſt a ſhare of them ſhould be retained in pots for moving to ſhelter of a frame in froſty weather.

*Tender Shrubby Kinds.*

[3]LOBELIA *Plumierii.*

*Plumier's Shrubby Lobelia.*] Hath a ſhrubby, ſomewhat ſucculent ſtalk, riſing five or ſix feet high; oval-oblong entire leaves, placed alternate; and from the ſides of the ſtalk, white flowers, growing by two or three together on long foot-ſtalks.

[4]LOBELIA *Surinamenſis.*

*Surinam ſhrubby Lobelia.*] Hath a ſhrubby ſtalk, riſing half a yard high; oblong, ſerrated, ſmooth leaves; and flowers from the axillas on very long foot-ſtalks.

[5]LOBELIA *Pinifolia.*

*Pine-tree-leaved Shrubby Lobelia.*] Hath a ſhrubby ſtalk, riſing a yard high; linear entire leaves in cluſters; and blue flowers from the ſides of the ſtalks.

The flowers of all theſe ſpecies of Lobelia conſiſt only of one petal, cylindrically tubular below, and divided at top into five parts, ſee the *Characters*; thoſe of the herbaceous kinds are ſometimes ſucceeded here by ſeeds, but rarely any of the others.

The two firſt ſpecies are very ornamental flowery plants, for the principal compartments of the pleaſure-garden; but being but moderately hardy, liable to ſuffer by ſevere froſt, it is proper to keep ſome alſo in pots to move to occaſional ſhelter in froſty weather, they produce extremely ſhowey garden-flowers; more particularly the *Lobelia Cardinalis*, in its beautiful ſcarlet ſpikes, occupying half the length of the ſtalks, conſiſting of numerous flowers; but both the ſorts make a fine appearance for a month or ſix weeks; ſo both demand a place in every curious collection, to encreaſe the variety of herbaceous flowery perennials, and for which purpoſe they have been long retained in moſt of our eminent gardens, and are kept in all the nurſeries for ſale.

The other three tender ſhrubby ſorts being natives of the hot parts of America, Aſia, and Africa, require a hot-houſe here, ſo muſt be kept in pots, and retained in that department, the firſt of them as the moſt common in the Engliſh gardens.

*Propagation.*

The two hardy herbaceous kinds are propagated by ſeed, cuttings of their ſtalks, and by parting their roots.

By Seed.—They riſe from ſeed one year, and flower the next, and abide ſeveral years. Sow the ſeed in autumn, or early in ſpring in a warm border, or in pots or boxes to move to different ſituations in different ſeaſons, to have ſhelter from froſt, and ſhade from the mid-day ſun in ſummer, &c. obſerving thoſe ſowed in autumn generally come up more freely the following ſpring than thoſe which are ſown in that ſeaſon; allow ſhelter in hard froſts, as juſt obſerved, either under a frame, or awning of mats, but ſhould be fully expoſed in all mild weather; giving occaſional watering in ſpring and ſummer. When the plants are come up two or three inches, prick them out in ſeparate ſmall pots of rich earth, give water, and place them in the ſhade till freſh rooted, repeating the waterings occaſionally in hot dry weather, and ſhift them into larger pots as they ſhall require; in winter move them into a frame to have occaſional ſhelter from inclement weather; and in ſpring, in March, ſome of them may be turned out into the full ground, when they will flower the enſuing ſummer; and ſome may be retained in pots to move to ſhelter in winter, to be as a reſerve in caſe thoſe

thoſe in the open air ſhould be killed by froſt; theſe will alſo flower at their uſual time in ſummer.

As theſe beautiful plants generally flower in the greateſt perfection in the firſt and ſecond year of their bloom, it is proper to raiſe a ſupply of new plants every year or two, in order to have them to flower in their utmoſt perfection annually.

By Off-ſets.—Both theſe hardy ſorts ſometimes afford off-ſets for young plants from their ſides at bottom, which may be ſeparated in autumn, and potted, and managed as for the ſeedlings.

By Cuttings.—In June, if ſome of the young ſtalks are divided into lengths of five or ſix inches, planted in an eaſterly border, two parts of three deep, covered down with hand-glaſſes, and watered occaſionally; they will emit roots, and form young plants in a month or ſix weeks; the glaſſes ſhould then be taken away, and manage the plants as above.

The tender kinds are propagated by ſeeds procured from abroad, ſowing them in pots of light ſandy earth, and plunged in the bark-bed; and when the plants are three inches high, plant them in ſeparate pots, and plunged alſo in the bark bed, giving water and occaſional ſhade till rooted.

Theſe ſorts muſt always remain in the hot-houſe, and have frequent moderate waterings.

LOCULAMENTA, *Loculi*, Cells, or Pockets, the internal diviſions, or departments of a capſule or other dry ſeed-veſſel.

Theſe *Loculi*, or Cells, are thoſe departments of a ſeed-veſſel which immediately contain and incloſe the ſeeds; and in point of number, ſome capſules have but only one Cell, others two, three, or many; when of one Cell it is termed *unilocular*; when of two, *bilocular*; of three, *trilocular*; of four, *quadrilocular*; of five, *quinquelocular*; of ten *decemlocular*; of many, *multilocular*, &c. each Cell having, ſome but one, others ſeveral ſeeds; it being various in different genera.

LONICERA Honeyſuckle.

This genus retains a grand collection of celebrated deciduous flowering ſhrubs and ſome ever-greens, proper for all ornamental plantations, conſiſting both of upright growers, and twining climbers, riſing from three or four to ten or twelve feet high; adorned with oblong, oval, and cordated moſtly oppoſite leaves, and a great profuſion of elegant monopetalous, tubular, five-parted, very fragrant flowers, moſt part of ſummer.

Claſs and order, *Pentandria Monogynia*.

*Characters.*] CALIX, is ſmall, five-parted, and reſts on the germen. COROLLA, is monopetalous and tuberous, having an oblong gibbous tube, divided above into five reflexed ſegments. STAMINA, five ſubulate filaments, and oblong antheræ. PISTILLUM, a roundiſh germen under the receptacle, filiforme ſtyle, and obtuſe capitated ſtigma. PERICARPIUM, an umbellicated bilocular berry, containing roundiſh compreſſed ſeed.

In this genus are now comprehended as ſpecies, ſeveral genera of former botaniſts, ſuch as the *Diervilla*, *Symphoricarpos*, or St. Peter's-wort, *Periclymenum*, &c. Linnæus diſcovering their flowers to poſſeſs equally the ſame *Characters* as Lonicera, has retained them all as ſpecies only of this genus.

They may be divided into two claſſes, the upright growers, and trailers.

*Upright Kinds.*

Theſe ſorts riſe with upright firm ſtalks, branching moderately, their branches moſtly ſupporting themſelves tolerably erect, forming low, upright, buſhy heads; they are all hardy, deciduous, and moſt of them produce ornamental flowers, which however, are rather inferior both in numbers, beauty, and fragrance, to thoſe of the trailing kind, but they nevertheleſs exhibit a pleaſing elegance, and agreeable variety, in their general appearance; and are very proper furniture for the ſhrubbery.

The ſpecies of the above kinds commonly retained in our gardens are:

LONICERA *Alpigena*.

*Alpine Upright Red-berried Honeyſuckle.*] Riſes with a ſhrubby, ſhort, thick, upright ſtem, branching ſtrong and erectly, four or five feet high; largiſh ſpear-ſhaped leaves, in pairs oppoſite; and from the ſides of the branches many red flowers, by twos on long footſtalks; each ſucceeded by two red berries joined together at their baſe; flowers in April and May, and the berries ripen in autumn.

[2]LONICERA *Cærula*.

*Blue-berried Upright Honeyſuckle.*] Riſes with a ſhrubby upright ſtem, branching moderately three or four feet high, the branches

covered with a purpliſh bark; oblong-lanceolate leaves, by pairs oppoſite; and from the ſides of the branches, many white flowers by twos on ſhort foot-ſtalks, each ſucceeded by a pair of blue berries joined together at the baſe: flowers in May, and the berries ripen in Auguſt.

[3]LONICERA *Nigra.*

*Black berried Upright Honeyſuckle.*] Riſes with a ſhrubby upright ſtem, branching three or four feet high; oblong, elliptical, entire leaves; and white flowers, ſucceeded by black berries, ſingle and diſtinct; flowering in May.

[4]LONICERA *Xyloſteum.*

*Xyloſteum, or Fly Honeyſuckle.*] Riſes a ſhrubby, ſtrong, upright ſtem, branching ſeven or eight feet high, the branches having a whitiſh bark; oblong-oval, downy leaves, in pairs oppoſite; and from each ſide of the the branches, erect white flowers, each ſucceeded by large double red berries, joined together at their baſe; flowers in June, and the berries ripen in September.

[5]LONICERA *Tartarica.*

*Tartarean Honeyſuckle.*] Riſes with a ſhrubby upright ſtem, branching erectly three or four feet high; heart-ſhaped oppoſite leaves; and whitiſh erect flowers, ſucceeded by red berries, ſometimes diſtinct and ſometimes double.

[6]LONICERA *Diervilla.*

*Diervilla, or Yellow-flowered Acadian Honeyſuckle.*] Riſes with ſhrubby upright ſtalks, branching erect, but moderately, three or four feet high; oblong, heart-ſhaped, pointed, ſerrated leaves, by pairs oppoſite; the branches terminated by racemus cluſters of pale-yellow flowers; flowers in May and June, continuing ſometimes till autumn, but rarely ripens ſeed here.

[7]LONICERA *Symphoricarpos.*

*Symphoricarpos, or Shrubby St. Peter's Wort.*] Riſes with a ſhrubby rough ſtem, branching erect four or five feet high, the branches ſlender and numerous; cloſely garniſhed with ſmall oval oppoſite leaves on ſhort foot-ſtalks; and ſmall greeniſh flowers round the ſides of the ſtalk; appearing in Auguſt.

*Trailing, or Climbing Kinds.*

Theſe ſorts have moſtly weak declinated ſtalks and branches, which, unleſs ſupported, trail along the ground, ſome ſorts rambling to a great length; but having ſupport of ſtakes, or ſtems of trees, &c. they will climb or twine round them many feet high, and often climb over the adjacent ſhrubs, hedges, or other ſupport in their neighbourhood, for they are all volubilate climbers, aſcending by twining ſpirally round any ſupport, generally to the left, according to the apparent motion of the ſun; they alſo, if trained againſt arbours, ſeats, walls, pales, &c. may be extended a conſiderable length, in the ſpace of one ſummer; ſome of the ſorts may alſo with a little trouble be trained as ſtandards, as hereafter directed.

They are moſtly of the deciduous tribe, except one ſpecies, and one or two varieties, which are ever-green: ſeveral of the ſorts are remarkable for having the upper leaves ſitting cloſe, uniting at their baſe, ſo as to appear perforated by the ſtalk or branch; and all the ſorts are remarkably floriferous; the flowers elegant and fragrant, generally continuing a month or two in ſucceſſion, and the evergreen kinds much longer.

The moſt material ſpecies of the above kinds are:

[8]LONICERA *Periclymenum.*

*Periclymenum, or Common Climbing Honeyſuckle.*] Comprehends two principal varieties; Engliſh wild honeyſuckle—Dutch honeyſuckle, &c. each of which furniſhing alſo ſome varieties.

*Engliſh Wild Honeyſuckle, or Woodbine of our Woods and Hedges.*] Riſes with ſhrubby, weak, very long, ſlender ſtalks and branches trailing on the ground, or climbing round any ſupport, and extend many feet in length; oblong-oval oppoſite leaves, diſtinct on ſhort foot-ſtalks; and all the branches terminated by oval imbricated heads, furniſhing ſmalliſh flowers of different colours in the varieties; flowering from June or July until autumn.

*Varieties of this*] With white flowers—with red flowers—with ſtriped leaves—oak-leaved, having the leaves ſinuated, or cut on the edges like thoſe of the oak-tree—ſtriped oak-leaved.

This ſpecies grows wild in England in great plenty in woods and hedges, and produce abundance of flowers, which however are ſmall, but by garden-culture they are much improved: the plant and all its above varieties have generally very weak trailing ſtalks and branches, that they cannot be trained with upright ſtems, and their flowers are generally ſmall; a few plants of each, however, are proper to introduce as climbers, to encreaſe the variety among the others.

The

The following varieties grow much ſtronger, and produce large and more elegant flowers.

*Dutch, or German Honeyſuckle.*] Riſes with a ſhrubby declinated ſtalk; and ſtrong ſhooting, long, trailing, purpliſh branches, advancing a conſiderable length; oblong-oval oppoſite leaves, diſtinct, on ſhort foot-ſtalks; and all the branches terminated by oval imbricated heads, furniſhing large beautiful red flowers, of fragrant odour; appearing in June and July.

*Varieties of this*] Long-blowing, red, German honeyſcuckle—late red-flowering——ever green late red-flowering, retaining its leaves all the year, and often its bloom till near Chriſtmas.

[9]LONICERA *Caprifolium.*

*Caprifolium, commonly called Italian Honeyſuckle.*] Riſes with ſhrubby declinated ſtalks, ſending out long, ſlender, trailing, twining, greeniſh branches; oval, cloſe-ſitting, leaves, by pairs oppoſite, the upper ones cloſely join at their baſe, appearing perforated by the branch; and all the branches terminated by verticillate or whorled bunches of cloſe-ſitting flowers of great fragrance, of different colours and time of flowering in the varieties.

*Varieties of this*] Early white-flowering, appearing in May—early red-flowering; appearing alſo in May—late red-flowering, appearing in June and July, and is a fine ſort—yellow flowered——ever-green red-flowering, the leaves large, thick, and remain all the year; and it flowers from June until the end of autumn.

This ſpecies and varieties are eaſily diſtinguiſhed, by producing their flowers in whorled bunches, appearing as if three or four bunches grew out of one another; are large, numerous, and ſweetly ſcented.

The following is alſo valuable for its large elegant flowers, but are almoſt devoid of ſcent.

[10]LONICERA *Sempervirens.*

*Ever-green Trumpet-flowered Honeyſuckle.*] Riſes with a ſhrubby declinated ſtalk, ſending out ſlender, long, trailing, reddiſh branches; oblong-oval, cloſe-ſitting, ſhining, ever-green leaves, in pairs oppoſite, the upper ones cloſely join at the baſe, appearing perforated by the ſhoot, and all the branches terminated by naked verticillate ſpikes of long, unreflexed, deep-ſcarlet flowers, of great beauty, but little fragrance.

This ſpecies and following varieties of it are alſo diſtinguiſhable by their flowers growing in whorled ſpikes.

*Varieties of this*] Large Virginia trumpet-honeyſcuckle, having large bright-ſcarlet flowers——minor Carolina trumpet-honeyſuckle, with ſmaller ſcarlet flowers.

Theſe are all the principal ſorts of *Lonicera* that merit culture in our gardens, and that are to be met with in the nurſeries for ſale.

The flowers of all the ten ſpecies and reſpective varieties, are of one ſingle, oblong, tubulous petal, it having the lower part a long tube, enlarging at top, and deeply divided into five, moſtly reflexed ſegments, (ſee the *Characters*) and thoſe of moſt of the ſorts are ornamental, but preference is due to thoſe of the trailing kinds, and which poſſeſs alſo the greateſt fragrance.

The plants of all the ſorts are ſhrubby, durable in root, ſtem, and branches; and ſo hardy as to grow in any common ſoil and ſituation, both in open expoſures, and under ſhades of trees, more particularly the trailing kinds.

They are all admirable furniture for ornamental plantations in gardens, both for the variety of their different growths, and ornament and fragrance of their flowers; though the flowers of the upright kinds are not ſo ſhowy as thoſe of the trailers; but they, however, exhibit an exceedingly agreeable variety. Thoſe of the trailing ſpecies have certainly the greateſt merit both in their numbers, ſize, elegance, and odour, as well as in duration: however, the ſhrubs of all the ſorts are proper to be introduced as plants of ornament in every ſhrubbery; the upright kinds to intermix as ſtandard ſhrubs, they having upright firm ſtems, and erect moderate-ſhooting branches, forming handſome heads; but the trailing kinds, whoſe branches are great ramblers, and without ſupport, trail along the ground, ſhould generally be introduced as climbers, having ſtout ſtakes placed to each for them to climb upon, which they effect by aſcending ſpirally round the ſupport, to a conſiderable height; and may alſo be placed to aſcend round the ſtems of trees, and to climb among the boughs of the adjacent buſhes, ſhrubs, and hedges, which they will effect in a very agreeable manner, by interweaving their branches therewith, mount aloft, ſpread about, and ſhow their flowers at top, appearing as if produced from the plant upon which they climb. In this manner may all the ſorts of *Lonicera*, both upright growers, and climbers, be made to ornament our gardens.

I ſhould

I ſhould adviſe to diſperſe plenty of the different trailing *Loniceras* near the ſides of all the principal walks, both for the beauty of their flowers, and for the delightful odour they conſtantly emit all around.

Theſe climbers are likewiſe proper for training againſt walls, &c. for the ornament and fragrance of their flowers, training their branches four or five inches aſunder; obſerving to thin out the ſuperabundant ſhoots annually, and train in ſome of the moſt robuſt for ſucceſſion wood, either at full length, or ſhortened as it may ſeem proper for the ſpace deſigned to fill.

Having obſerved above, that the trailing kinds are principally adapted for climbers, I would however remark, that with a little pains they may alſo be made to form low buſhy ſtandards; this is done by training them at firſt to one upright ſtem, by means of ſtakes, and prune their rambling young ſhoots every year, as ſhort as you ſhall ſee occaſion, ſo as to keep them within proper bounds; by this practice they may be made to form tolerable ſtandard ſhrubs, with erect firm ſtems, and buſhy heads.

The ever-green kinds of theſe ſhrubs are principally all of the trailing tribe, and have ſingular merit, not only in their ever-green foliage, plentitude, and elegance of their flowers, but in their long continuance in bloom, which is frequently from June till November, and ſometimes till Chriſtmas, and after, in mild ſeaſons; and thoſe of the *Lonicera Caprifolium*, or Italian kind, impart a moſt agreeable fragrance: all of which kinds having long trailing twining branches, will form beautiful climbers; they may alſo be trained as ſtandards by the means of ſupporting their ſtems at firſt, and ſtopping their young ſhoots as hinted above; but the Italian ſort being the ſtrongeſt ſhooter is the beſt for this purpoſe.

As to the general culture of all the ſorts, they require very little; the upright ſorts in particular, require to have only their ſtraggling ſhoots ſhortened, and dead wood cut out; and the trailing kinds, which are trained as climbers, muſt have their branches conducted in a proper manner upon their reſpective ſupports; and every year all rambling ſhoots muſt be reduced and trained as you ſhall ſee proper, ſo as to preſerve them within due limits, except you deſign they ſhall run wild in their own rural way, eſpecially thoſe intended to climb among the branches of trees, ſhrubs, and buſhes; thoſe alſo intended to cover arbours and ſeats, ſhould be pruned and trained annually, laying the ſhoots along at their length, eſpecially till they have covered the allotted ſpace; ſhortening or clearing out, however, all ſuch ſtragglers which cannot be properly trained; likewiſe ſuch of thoſe ſorts as are trained againſt walls, &c. muſt have an annual pruning and training, by going over them two or three times in ſummer, laying in ſome of the moſt convenient proper ſhoots, ſome at their length, ſhortening or retrenching others as it ſhall ſeem neceſſary to preſerve regularity, and the proper ſucceſſion of flowers; obſerving, however, to train enough, at this time, of ſuch particularly as ſhall appear neceſſary to continue the bloom as long as poſſible; and in winter-pruning, thin out all thoſe left in ſummer, which may now appear ſuperfluous or unneceſſary, and ſhorten all ſuch as are too long for the ſpace allotted for them, eſpecially all thoſe with weak ſtraggling tops; and nail in the remaining proper branches and ſhoots cloſe to the wall.

*Propagation of all the Sorts.*

The propagation of all the ſorts is effected by layers and cuttings, more particularly the latter; both of which readily emits roots and form plants in one year, fit to tranſplant; ſome ſorts are alſo propagated by ſuckers, and by ſeed.

By Layers.——In autumn, winter, or ſpring, lay a quantity of the lower young ſhoots of the former ſummer, by ſimple laying, ſhortening their ſtraggling tops, they will be well rooted by autumn following, each commencing a good plant, and ſhould be taken off and planted in nurſery rows for a year or two, to acquire proper ſize and ſtrength for uſe.

By Cuttings.——Any time from October till March is the proper time for this work, but the ſooner the better; and by which method prodigious quantities of the plants may be raiſed, as almoſt every cutting will readily grow. Chuſe the young ſhoots of the former ſummer, the ſtrongeſt and moſt robuſt, and which divide into cuttings from about ſix or eight to ten or fifteen inches long, plant them in rows in any ſhady border of common earth, a foot aſunder, and half that diſtance in each row, or cloſer if great quantities are required, putting each cutting two parts out of three, or more, into the ground, they will take root freely

freely without any trouble, and ſhoot at top, ſo as to form proper plants by autumn or winter following, at which time they may be tranſplanted into the nurſery quarters, to have more room to grow, placing them in rows two feet diſtance, and a foot apart in the rows; where let them remain a year or two, or till wanted for the ſhrubbery.

By Suckers.—The *Lonicera Diervilla* ſends up annually abundance of ſpawn, or ſmall ſuckers from the root, by which it may alſo be propagated, each of which taken up in autumn or winter, and planted in the nurſery will form a proper plant; obſerving this ſort is likewiſe propagated with great eaſe by layers and cuttings as above.

By ſeed —Several of the upright ſorts, and others, furniſh plenty of ſeeds, which if ſowed in autumn, in a bed of common mould, an inch deep, many of the plants will probably riſe in ſpring, but a great part of them are apt to remain till the ſecond ſpring before they appear.

LOTUS, Bird's-foot Trefoil.

It conſiſts of herbaceous and underſhrubby plants for the pleaſure-garden and green-houſe, ſome trailers, and ſome of erect growth, from one to two or three feet high, adorned moſtly with trifoliate leaves, and papilionaceous ornamental flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, five-parted at top, and permanent. COROLLA, is papilionaceous, the ſtandard roundiſh and reflexed backward, the wings ſhorter, broad and roundiſh, and the keel ſhort and cloſed above. STAMINA, ten diadelphous filaments, and ſmall antheræ. PISTILLUM, an oblong taper germen, a ſimple ſtyle, and inflexed ſtigma. PERICARPIUM, a cloſe, cylindrical, bivalvular, unilocular pod, having numerous partitions ſeparating the ſeeds.

The name Bird's-foot Trefoil given to the plants of this genus, is derived from the fancied reſemblance of the bended ſeed-pods of ſome of the ſorts, to the toes of birds feet.

There are many ſpecies, but thoſe common to our gardens are, a hardy herbaceous annual for the pleaſure-garden, and four underſhrubby perennials for the green-houſe.

*Hardy Annual Kind.*

[1]LOTUS *Tetragonolobus.*

*Tetragonous Winged-podded Lotus, commonly called Winged Pea.*] Hath trailing, ſlender, branchy ſtalks, a ſoot long; garniſhed with trifoliate oval leaves, accompanied by two oval bractea at their baſe; and from the axillas of the branches large papilionaceous red flowers, one on each foot-ſtalk; ſucceeded by tetragonous ſolitary pods, having a membranous wing, or lobe, running longitudinally at each corner.

It flowers ornamentally in June and July, and the ſeeds ripen in autumn.

This plant is of the tribe of hardy annuals, and has been long cultivated as a flowery plant to adorn the flower-borders, &c. is generally ſowed in patches where the plants are to remain.

*Tender Green-houſe Kinds.*

Theſe kinds are perennial in root, and moſtly with durable ſtalks; are natives of diſtant warm countries, and require protection here from froſt, ſo muſt be kept in pots, and placed among the green-houſe plants.

The ſorts are;

[2]LOTUS *Creticus.*

*Cretan Silvery Lotus.*] Hath a ſlender underſhrubby ſtalk, riſing by ſupport three or four feet high; ornamented with trifoliate bright-ſilvery leaves; and from the ſides of the branches long foot-ſtalks, each terminated by ſeveral yellow flowers, ſucceeded by ſubternate pods.

[3]LOTUS *Jacobæus.*

*Jacobæus Lotus of St. James's Iſland.*] Hath upright herbaceous ſtalks, branching two or three feet high; adorned with narrow, ſpear-ſhaped, cloſe-ſitting, whitiſh leaves, ſometimes are trifoliate, and quinquefoliate; and from the upper part of the branches long ſlender foot-ſtalks, terminated each by three or five yellowiſh purple flowers, ſucceeded by ſubternate pods.

It flowers moſt part of ſummer and autumn, ſucceeded by plenty of ſeeds.

[4]LOTUS *Hirſutus.*

*Hairy Italian Lotus.*] Hath upright hairy ſtalks, branching a yard high; garniſhed with trifoliate hoary leaves; and from the ſides of the branches longiſh ſoot ſtalks, terminated by heads of whitiſh hoary-cupped flowers; ſucceeded by oval pods; flowers in June, and the ſeeds ripen in autumn.

[5]LOTUS *Dorycnium.*

*Dorycnium, or White Auſtrian Lotus.*] Hath underſhrubby ſmooth ſtalks, branching three or four feet high; five-lobed, hand-ſhaped, hoary leaves; and the branches terminated

minated by aphyllous heads of ſmall white flowers; ſucceeded by ſhort pods; flowers in June.

The flowers of all theſe ſpecies of Lotus are of the papilionaceous, or butterfly-ſhaped kind, compoſed each of four petals, i. e. a vixillum, two wings, and a carina. See the *Characters*.

The firſt ſpecies being a hardy annual of the flowery kind, is proper for ornamenting the compartments of the pleaſure-garden. It is raiſed from ſeed annually in ſpring, in the open ground, in the places where the plants are to remain to flower. Sow it any time in ſpring, from February till May, in patches in different parts of the garden, five or ſix ſeeds in each patch, half an inch deep; the plants will ſoon come up, which remaining in the ſame place for flowering, require only occaſional weeding, and may either be ſuffered to trail, according to their natural growth, or may tie them up to ſticks; they will flower equally well in either method, exhibiting their crimſon flowers very ornamentally.

This plant was formerly cultivated as an eſculent, for its young green ſeed-pods to dreſs and eat like peas, alſo in the manner of kidney-beans.

The green houſe kinds effect an agreeable variety in that collection, both in their foliage and flowers. They all require ſhelter from froſt, the two firſt of them in particular; but the two laſt are ſomewhat hardier, and will ſometimes ſucceed in the full ground all the year in a warm and dry ſituation, ſo may place ſome to take their chance; it, however, is proper to keep ſome of all the ſorts in pots of rich earth, in order for moving to ſhelter in winter.

The propagation of theſe green-houſe ſorts is by ſeed, and by cuttings.

By Seed.—Sow it in April in a warm border; or, to bring them more forward, in a moderate hot-bed; and when the plants are about three inches high, plant them in ſeparate ſmall pots of light rich earth, give water, and place them in the ſhade till freſh-rooted.

By Cuttings.——Cuttings of the young ſtalks and branches, planted any time from April till July, in beds or pots of rich mould, giving ſhade and water, they will emit roots, and form plants in a few weeks, but may be greatly facilitated by covering them cloſe with hand-glaſſes till they begin to ſhoot at top, then inure them gradually to the air, and ſoon after may be tranſplanted into ſeparate pots.

LUNARIA, Moonwort, Sattin-flower, or Honeſty.

The plants are tall, herbaceous, ornamental annuals and perennials, of upright branchy growth, for the pleaſure-garden, riſing two or three feet high, garniſhed with heart-ſhaped, and oval-lanceolate leaves, and cluſters and ſpikes of tetrapetalous cruciforme flowers; ſucceeded by broad, roundiſh, moon-ſhaped, flat, very thin pods, of a ſattin colour, ſo tranſparent as to diſcover the ſeed through them; hence it is commonly called Honeſty.

Claſs and order, *Tetradynamia Siliculoſa*.

*Characters.*] CALIX, four oblong-oval deciduous leaves. COROLLA, four large, obtuſe, cruciforme petals. STAMINA, four long and two ſhorter filaments, and erect, patent antheræ. PISTILLUM, a pedicellated oval oblong germen, very ſhort ſtyle, and an obtuſe entire ſtigma. PERICARPIUM, a large elliptical plane, compreſſed, very thin, bilocular pod, erected on a ſmall foot-ſtalk, containing kidney-ſhaped, compreſſed, bordered ſeeds.

There are but two ſpecies, an annual and perennial, the former of which has been long a reſident of our gardens, commonly known by the name of Honeſty.

The ſpecies are:

1 LUNARIA *Annua*.

*Annual Lunaria, commonly called Sattin-flower, or Honeſty.*] Hath fibrey roots, crowned by large heart ſhaped leaves; amidſt them an upright reddiſh flower-ſtalk, branching all around, a yard high, adorned with heart-ſhaped leaves, oppoſite below and ſitting cloſe above; and from the ſides and ends of all the branches cluſters of cruciforme purple flowers, ſucceeded by numerous, broad, moon-ſhaped, white, ſattiny, pellucid pods.

*Variety.*] Large podded ſattin-flower, or honeſty.

Both the varieties flower in May or June, and their pods and ſeed ripen in autumn; the ſeed-pods being numerous, white ſattin-like, and tranſparent, exhibit a ſingularly agreeable appearance; and as they remain long on the branches, the ſtalks are often cut off in September, and dried, then tied in ſpreading bunches, to place in large rooms all winter, where they will appear very ornamental, more eſpecially if the pods are diveſted of their

their outer huſks, they will be whiter, more fattiny and ſhining.

²LUNARIA *Rediviva.*

*Redivive Sweet-ſcented Moon-wort.*] Hath fibrated perennial roots; upright, firm, tough ſtalks, branching two feet high; garniſhed with oval-ſpear-ſhaped, rough leaves, placed alternate above; and the branches terminated by ſpikes of ſweet-ſcented flowers, of different colours in the varieties; ſucceeded by oblong flat pods.

*Varieties.*] With purple flowers—with white flowers—and with yellow flowers; all flowering in June, ſucceeded by pods and ripe ſeeds in autumn, having the ſame property as the former.

The flowers of both the ſpecies, and reſpective varieties are cruciforme, and conſiſt each of four heart-ſhaped petals, are numerous on each plant and conſpicuous.

Both the ſpecies and their varieties are very hardy, and will grow any where; the firſt ſort decays annually after having flowered and ſeeded; but the perennial is of ſeveral years duration in root, eſpecially if cultivated in a dry ſandy, or rubbiſhy ſoil.

The firſt ſpecies, *Lunaria Annua*, however, may be conſidered both as an annual and biennial; for, as an annual, being ſowed early in ſpring, it will come up the ſame ſeaſon, and often run up to flower, perfect ſeeds, and wholly periſh in autumn; and as a biennial, if ſowed in ſummer, or early in autumn, it will riſe the ſame year, ſtand the winter, flower early in ſummer, perfect ſeeds in autumn, and then totally periſh; for conſidered either as annual or biennial, it always decays root and branch ſoon after the ſeeds are ripe; remarking that the autumn-ſowed plants always grow ſtrongeſt, and from ſcattered or ſelf-ſown ſeeds, numbers of young plants will riſe ſpontaneouſly.

But as to the ſecond ſort, it being once raiſed, it remains perennial in root, ſending up freſh ſtalks annually in ſpring for flowering, which always decay as ſoon as they have perfected ſeeds.

The propagation of both the ſpecies, &c. is by ſeed, in the natural ground in autumn or ſpring, either in patches to remain, or in beds for tranſplantation. By the former method the plants are generally ſtronger than thoſe which are tranſplanted; but they ſucceed very well both ways; obſerving, when deſigned to ſow them in patches, to put ſeveral ſeeds in each, half an inch deep, and when the plants come up, leave only one of the beſt in each patch; and if intended to ſow any for tranſplantation, ſow them evenly on any bed or border, and rake them in; and when the plants are two or three inches high plant them out, the annual ſorts where they are finally to remain to flower; and the perennials either where they are to remain, or in nurſery beds till autumn, then to be planted out for good.

LUPINUS, Lupine.

This genus conſiſts of hardy, herbaceous, flowery annuals, and a perennial, all for the pleaſure-garden, riſing with upright ſtalks, from about a foot to three or four high; ornamented with digitate, or fingered leaves, and terminated by long whorled ſpikes of papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous and bifid. COROLLA, is papilionaceous, the vexillum roundiſh-cordated, emarginated, with the ſides reflexed and compreſſed, the wings nearly oval, and join at their baſe, and a narrow, falcated, acuminated carina. STAMINA, ten diadelphous filaments, and roundiſh-oblong antheræ. PISTILLUM, an awl-ſhaped compreſſed germen, ſubulated ſtyle, and obtuſe ſtigma. PERICARPIUM, a large oblong, compreſſed, acuminated, coriaceous, unilocular pod, containing ſeveral roundiſh compreſſed ſeeds.

There are about ſeven ſpecies, ſix annuals and one perennial, all hardy, and moſtly plants of ornament, both in their finely digitate leaves, and variety of their flowers.

*Annual Kinds.*

Of theſe kinds there are about four or five ſpecies common to our gardens; have all fibrated roots, each plant riſing with one upright branchy ſtalk, as in their deſcription.

LUPINUS *Lutea.*

*Yellow Lupine.*] Riſes with an upright ſtalk, branching a foot or eighteen inches high; garniſhed with digitate leaves, of eight or nine long narrow lobes; and the ſtalks and branches terminated by looſe whorled ſpikes of yellow flowers, having verticillate cups with appendages, the upper lip bipartite, and the under one tridented; flowers in June and July.

The flowers of this have a ſweet fragrance, for which peculiar merit it is in great eſtimation.

[2]LUPINUS *Hirſutus.*

*Hairy Giant Lupine.*] Riſes with an upright, thick, downy, hairy ſtalk, branching ſtrongly three or four feet high; garniſhed with digitate hairy leaves, of from nine to eleven, oblong, wedge-ſhaped, ſilvery-white lobes; and the ſtalk and branches terminated by long whorled ſpikes of large flowers, of different colours in the varieties, having alternate cups with appendages, the upper-lip bipartite, the under one tridented.

*Varieties.*] With blue flowers——with fleſh-coloured flowers, commonly called Roſe Lupine. The flowers of both varieties are large and ſhowey, appear in July, and are ſucceeded by large, broad, hoary ſeed-pods.

[3]LUPINUS *Anguſtifolia.*

*Narrow-leaved Tall Blue Lupine.*] Riſes with an upright firm ſtalk, branching a yard high; digitate large leaves, of nine or ten oblong, obtuſe, blueiſh lobes; and the ſtalks and branches terminated by whorled ſpikes of blue flowers, having alternate cups with appendages, the upper-lip bipartite, and the under entire; flowers in July.

[4]LUPINUS *Varius.*

*Variegated-ſeeded Blue Lupine.*] Riſes with an upright firm ſtalk, two feet and a half high; digitate leaves, of ſix or ſeven oblong hairy lobes, and the ſtalk and branches terminated by ſpikes of blue flowers, having ſemi-verticillate cups with appendages, the the upper-lip bifid, and the under almoſt tridented; and with variegated ſeed.

[5]LUPINUS *Alba.*

*White Lupine.*] Riſes with an upright thick ſtalk, branching two feet high; digitate leaves of ſeven or eight narrow hairy lobes, covered with a ſilvery down; and the branches ending in looſe ſpikes of white flowers, having alternate cups without appendages, the upper lip entire, and the under tridented.

All theſe annual Lupines riſe from ſeed ſowed annually in ſpring and ſummer in the open ground, arrive to full growth in June and July, when they flower, and ripen ſeed abundantly in autumn, then the plants totally periſh root and branch.

They are all very ornamental in the pleaſure-garden, but the yellow ſort claim precedence for the ſweetneſs of its flower.

*Perennial Kind.*

There is but one ſort, it is perennial in root, and annual in ſtalk.

[6]LUPINUS *Perennis.*

*Perennial Blue Virginia Lupine.*] Hath long fibrated, creeping, deeply-penetrating roots; upright channelled ſtalks, branching near two feet high; digitate leaves of eight or ten ſpear-ſhaped narrow lobes; and the branches terminated by looſe ſpikes of blue flowers, having alternate cups, without appendages, the upper-lip emarginated, and the under one entire; flowers in June.

All the ſpecies flower in June and July, and ripen plenty of ſeeds in autumn.

The flowers of all the ſorts are papilionaceous, conſiſting of four petals, that is, a ſtandard, two wings, and carina (ſee the *Characters*), and grow in erect ſpikes, often diſpoſed in whorls one above another; which in all the ſorts, are ſucceeded by oblong compreſſed, legumenous pods, containing from three to five or ſix roundiſh flat ſeeds.

The leaves of all theſe plants are beautifully digitated into many lobes, ſtand moſtly upon long foot-ſtalks, and exhibit an agreeable variety.

The plants of all the ſorts ſucceed in any of the open borders, &c. and effect a fine variety, as well as very ornamental appearance; and are all eaſily raiſed from ſeed, which ſhould generally be diſpoſed in ſmall patches in the different flower compartments, in the places where it is deſigned the plants ſhall flower; placing ſome more forward, and others backward, according to their order of growth; obſerving the annuals muſt be raiſed annually, as they always periſh ſoon after they have flowered and ripened ſeeds; but the perennial ſort, once raiſed is of ſeveral years duration.

*Propagation, &c. of all the Sorts.*

The propagation of all the ſorts is effected with the utmoſt facility by ſeed in the full ground in March, April, and May; obſerving, that as too copious moiſture is apt to rot the ſeed, they ſhould not be ſowed earlier than the middle or latter end of March, except on very dry warm ſoils.

The annual ſorts ſhould always be ſowed at once in the places where it is intended the plants are to flower, for they do not ſucceed by tranſplantation; and to have a long ſucceſſion of bloom, about three or four different ſowings may be neceſſary, from about the middle or latter end of March until June, eſpecially the yellow ſort, whoſe bloom is rather of ſhort duration; obſerving to ſow all

the

the ſorts in patches, four, five, or ſix ſeeds in each, near an inch deep; and when the plants come up, leave only three of the beſt of them, though of the large kind one or two may be ſufficient in each place. When large quantities are required for noſegays, to ſupply the markets, &c. as practiſed about London with the yellow ſweet-ſcented ſort, they may be ſowed in rows in beds, drilling them in an inch deep, allowing a foot between the rows. In either mode of ſowing all the ſorts, let the plants remain in the ſame place for flowering, as above mentioned, and keep them clean from weeds, which is all the culture they require; and by repeated ſowings at a month's interval, the bloom may be continued from June or July until September or October; and the firſt ſown plants will furniſh plenty of ripe ſeed.

If ſome ſeeds are ſowed in autumn, in September, in a warm dry ſituation, the plants will come up, and often ſtand the winter tolerably well, and flower early the following year; or, if ſome are ſowed in pots, eſpecially the giant ſort, compriſing the large blue, and the roſe Lupine, which in wet autumns ripen ſeed but indifferently; ſo that by placing the pots in a garden frame, to have occaſional protection from hard froſt, they will flower early in the following ſummer, ſo as to perfect ſeeds before they are attacked by the autumnal rains.

The perennial ſort may be ſowed either in patches in the different compartments, as already obſerved, for the plants to remain where ſowed; or may be ſowed in beds in drills, for tranſplantation; but as the plants generally ſend their roots deep into the ground, they generally ſucceed beſt when permitted to remain where raiſed, than by removal; however, both methods may be practiſed occaſionally, and the plants once raiſed remain durable in root many years, ſending up new ſtalks annually in ſpring.

LYCHNIS, *Lychnis*, or Campion, including alſo the Bachelors-button, Catch-fly, &c.

It conſiſts of hardy, herbaceous, very floriferous ornamental perennials, of upright growth for the pleaſure-garden, riſing with erect firm ſtalks, two or three feet high, adorned at each joint with long ſpear-pointed leaves; and all the ſtalks terminated by cluſters and ſpikes of quinquepetalous, very conſpicuous flowers, of different colours in different ſpecies.

Claſs and order, *Decandria Pentagynia.*

*Characters.*] CALIX, is monophyllous, tubulous, five-parted at top, and permanent. COROLLA, five petals, having long tails, or ungues, the upper part, or limb, broad plane, and in ſome cut into ſegments. STAMINA, ten long filaments, alternately arranged, and attached to the ungues of the petals, and incumbent antheræ. PISTILLUM, a ſuboval germen, five long ſtyles, and reflexed downy ſtigma. PERICARPIUM, an oval, *unilocular*, quinquevalvular, covered capſule, having numerous roundiſh ſeeds.

There are about ſeven ſpecies, but not more than four that have merit as garden-plants, viz. the ſcarlet Lychnis—Bachelors-button—Catch fly——Ragged Robbin: each compriſing ſome varieties.

The ſpecies are;

[1]LYCHNIS *Chalcedonica.*

*Chalcedonian Scarlet Lychnis.*] Hath a fibrated perennial root; upright, ſtraight, hairy, annual ſtalks, riſing three or four feet high; garniſhed with long, ſpear-pointed, cloſe-ſitting leaves, by pairs oppoſite; and the ſtalk crowned by a large, compact, flat bunch of beautiful ſcarlet, or flame-coloured flowers; appearing in June and July.

*Varieties.*] With ſingle ſcarlet flowers—with large, double, ſcarlet flowers, of exceeding beauty and elegance——with pale-red flowers—with white flowers.

Of theſe varieties of this ſpecies, the double ſcarlet Lychnis is ſuperior to all for ſize and elegance, the flowers being large, very double, and collected into a very large bunch, and exhibit a charming appearance; the ſingle ſcarlet kind is alſo very pretty; and the others effect an agreeable variety with the ſcarlet kinds. All the ſingles furniſh plenty of ſeed, by which they may be raiſed abundantly; but the double, by its multiplicity of petals, exclude the generative organs, rarely ever produce ſeed, ſo can only be propagated by ſlipping the roots, and by cuttings of its flower-ſtalks. See the *Propagation.*

[2]LYCHNIS *Dioecia.*

*Dioecious Lychnis, commonly called Bachelors-button.*] Hath fibrated perennial roots; upright ſtalks, branching very diffuſe and irregular, two or three feet high; having oval, acute-pointed, rough leaves, by pairs oppoſite; and all the branches terminated by cluſters of dioeceous flowers of different colours and properties in the varieties; flowering in April and May.

*Varieties.*] Common ſingle red-flowered Bachelors-button——double red——double white—and ſingle white-flowered.

The double varieties are exceedingly ornamental in their bloom; the flowers large, very double, and continue long in blow; the ſingle red ſort grows wild by ditch ſides, and other moiſt places in many parts of England; from which the doubles were accidentally obtained by culture in gardens, and are propagated only by ſlipping the roots; and the ſingles, both by roots and by ſeed.

The flowers are often dioecious, i. e. male and female on diſtinct plants.

[3]LYCHNIS *Viſcaria.*

*Viſcous, German Lychnis, commonly callea Catch-fly.*] Hath fibrey perennial roots; crowned by a tuft of long, graſſy leaves cloſe to the ground; many erect, ſtraight, ſingle ſtalks, riſing a foot and a half or two feet high, exſuding from their upper part a viſcous or clammy matter; garniſhed with long narrow leaves, by pairs oppoſite; and terminated by many reddiſh-purple flowers, in cluſters one above another, forming a ſort of long looſe ſpike; all the flowers with entire petals; flowering in May.

*Varieties.*] With ſingle red flowers—with double red flowers—with white flowers.

The double variety is conſiderably the moſt eligible for general culture, and is propagated in plenty by parting the roots.

All the varieties of this ſpecies emitting a glutinous liquid matter from their ſtalks, and flies happening to light thereon, ſometimes ſtick and entangle themſelves, the plant thereby obtained the name Catch-fly.

[4]LYCHNIS *Flos-cuculi.*

*Cuckoo-flower Lychnis, commonly called Ragged Robin.*] Hath fibrey perennial roots; upright, branchleſs, channelled ſtalks, riſing near two feet high; garniſhed with long, narrow, ſpear-ſhaped leaves, in pairs oppoſite; and terminated by branchy foot-ſtalks, ſuſtaining many purple, deeply quadrifid flowers; appearing in May.

The flowers having each petal deeply quadrifid in a torn or ragged-like manner, the plant obtained the cant name of Ragged Robin.

*Varieties.*] With ſingle flowers—double flowers. The double ſort is a large, very multiple, fair flower, is an improved variety of the ſingle, which grows wild in moſt of our moiſt meadows, and is rarely cultivated; but the double, being very ornamental, merits culture in every garden; it, like the other double Lychniſes, rarely produces ſeed, but is eaſily propagated by ſlipping the roots.

All the four ſpecies and reſpective varieties are very hardy; all fibrous-rooted, the roots perennial; but are annual in ſtalk, which riſes in ſpring, flower in ſummer, ſucceeded in the ſingles by plenty of ſeed in autumn; by which all the ſingle varieties may be raiſed in abundance, but the doubles only by dividing the roots, and ſome by cuttings of the flower-ſtalks.

The flowers of all the ſorts, conſidered ſeparately, are ſmalliſh, but their numbers on each plant renders them conſpicuous; each flower in its ſingle ſtate, is compoſed of five plane petals, (ſee the *Characters*); but in the doubles, the petals are numerous; the ſingles ſucceeded by plenty of ſeed, but the doubles rarely any.

All theſe plants are very ornamental furniture for the pleaſure-garden, particularly the doubles, and will proſper in any common ſoil, will remain in all weathers unhurt, and each individual be of many years duration in root, which when of ſome ſtanding, ſend up many ſtalks every ſpring, and which being all terminated by numerous flowers, make a fine appearance in ſummer; but the ſcarlet Lychnis claims preference, eſpecially the double kind, which is ſingularly beautiful, even the ſingle ſcarlet ſort is alſo very ſhowy and pretty, and by ſome preferred to the double; all the other ſpecies, however, in their reſpective double-flowered ſtates, are pretty ornaments for the principal compartments of the pleaſure-ground.

All the ſorts are kept in the nurſeries for ſale; and having a few plants of each, may ſoon encreaſe the ſtock.

They may be planted any time from October till March in open weather, though if in autumn the better; obſerving to place the talleſt growers the moſt backward, the others more toward the front, according to their ſeveral degrees of height.

All the culture they require, is the clearing them from weeds in ſummer, in common with the other plants of the ſame compartments; ſupporting with ſtakes the ſtalks of thoſe which ſhall need it, and cutting down the decayed ſtalks in autumn.

*Propagation of all the Sorts.*

The propagation of all the ſorts is exceeding eaſy; all the ſingles by ſeed, and parting the

the roots; and the doubles by dividing or ſlipping the roots only, ſometimes alſo by cuttings of their ſtalks; all performed in the full ground.

By Seed.——The ſingles may be raiſed in great plenty this way, though but few of them except the ſingle ſcarlet Lychnis, are worth raiſing, ſince the doubles may be ſo eaſily encreaſed by ſlipping the roots, &c. March or April is the proper time for ſowing, chuſing a bed or border of light earth, which being dug, ſow the ſeeds on the ſurface, each ſort ſeparate, and rake them in; the plants will come up in two or three weeks, give occaſional waterings and hand-weeding; and in June, when the plants are two or three inches high, plant them out in beds or borders, in rows ſix inches aſunder; water them till freſh rooted, and let them remain till October, then tranſplant them where they are to remain, and they will all flower the following ſummer.

By Slipping the Roots.—All the ſorts, both ſingle and double, may be propagated by this method, but is more particularly applicable to the doubles, becauſe they cannot with certainty be obtained from ſeed; the beſt ſeaſon for performing this work is autumn, after the ſtalks decay; it, however, may alſo be done in the ſpring: the ſcarlet Lychnis affords offſets the moſt ſparing of any; all the others afford plenty; as to the method of ſlipping them, the whole root may either be taken up and divided into as many ſlips as are furniſhed with proper root-fibres, or the main root may ſtand, and ſlip off as many of the outer off-ſets as ſhall ſeem convenient; if the ſlips taken off in either method are tolerably ſtrong, the beſt of them may be planted at once where they are to remain; but if rather ſmall and weak, it is the moſt eligible to plant them in nurſery-rows, half a foot aſunder, to remain a year, then tranſplant for good.

By Cuttings of the Stalks.—This is more particularly neceſſary for the double ſcarlet Lychnis, when it encreaſes but ſparingly by off-ſets of the root. The work is performed in ſummer, when the ſtalks are well advanced in growth, but before they flower, or have become hard and woody: cut ſome of them off cloſe to the bottom, and divide them into lengths of from three to five joints, and plant them in an eaſterly border of rich earth, putting them two parts of three, or more, into the ground, leaving only one joint out; give water directly, and repeat it, together with occaſional ſhade in hot weather, and they will be well rooted, and form proper plants fit to tranſplant in autumn.

If the above cuttings, as ſoon as planted, are covered down cloſe with hand-glaſſes, it will greatly promote their rooting, ſo as to form ſtronger plants before winter.

LYCIUM, Box-thorn.

This genus retains three ſhrubby exotics of Africa, &c. for the green-houſe and ſhrubbery, riſing from about ſix or eight to ten feet high, armed with ſpines, and adorned with ſmall entire leaves, and monopetalous infundibuliforme flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is ſmall, obtuſe, erect, five-parted, and permanent. COROLLA, one funnel ſhaped petal, having a cylindric incurved tube, divided above into five ſmall ſegments. STAMINA, five ſhort ſubulated filaments, and erect antheræ. PISTILLUM, a roundiſh germen, ſimple ſtyle longer than the ſtamina, and thick bifid ſtigma. PERICARPIUM, a roundiſh bilocular berry, and numerous reneiforme ſeeds.

The ſpecies known in our gardens are;

LYCIUM *Afrum.*

*African Narrow-leaved Box-thorn.*] Hath ſhrubby irregular ſtalks, branching nine or ten feet high, the branches whitiſh, crooked, knotty, and armed with long ſharp ſpines; numerous ſmall linear leaves in cluſters, of different ſizes in each cluſter, the ſmaller ſtanding at the baſe of the larger; and purple flowers on ſhort foot-ſtalks from the ſides of the branches.

²LYCIUM *Barbarum.*

*Barbary Roſemarinus-leaved Lycium.*] Hath ſhrubby ſtalks, branching irregularly ſix or ſeven feet high, the branches whitiſh, and armed with thorns; ſmall ſpear-ſhaped, oval, thick, whitiſh leaves, placed irregularly; and ſmall white flowers from the ſides of the branches, having bifid cups; flowers in June.

Of this ſpecies are the two following varieties, both ſhrubby trailers, of hardy temperature; they were formerly conſidered as diſtinct ſpecies, but obſervation has determined them to be varieties only of the above ſpecies, *Lycium Barbarum:*

*Trailing Broad-leaved Barbary Lycium.*] Hath ſhrubby, declinated, very diffuſed ſtalks and branches of trailing growth, advancing irregularly many feet in length, ſpread about every way, and armed with very long thorns;

large

large, oval, ſpear-ſhaped, thick, whitiſh-green leaves, growing on all ſides by threes; and purpliſh flowers, ſingly on ſhort foot-ſtalks from the ſides of the branches, having bifid cups; flowering from Auguſt till October.

*Trailing Narrow-leaved Barbary Lycium.*] Hath ſhrubby, very branchy ſtalks, of trailing growth, ſpreading irregularly every way, armed with ſhort thorns; long, lanceolate, narrow, alternate, whitiſh-green leaves; and ſmall flowers, having bifid cups; flowering in June and July.

The flowers of all the ſorts conſiſts of one funnel-ſhaped petal, with an incurved tube, divided above into five parts; ſee the *Characters*.

All the four ſorts are durable in root, ſtem, and branches, and both the ſpecies are evergreen, retaining their leaves all the year; and they all flower here annually in ſummer.

The two ſpecies being ſomewhat tender require protection from froſt, ſo muſt be kept principally in pots, and placed among the green-houſe plants, where, as being cloſely garniſhed with numerous ſmall foliage, they will effect an eligible variety in that collection; ſome of them may alſo be placed in a warm part of the ſhrubbery to take their chance, and will ſucceed tolerably, except in very ſevere winters.

But the two varieties of the *Lycium Barbarum* are hardy, ſucceed in the open ground the year round, and are proper for the ſhrubbery, to introduce as trailers or climbers, for their branches trail and ramble about every way, ſo ſhould have ſupport of ſtakes, &c. to train them upon.

They all ſucceed in any common earth of a garden; let the green houſe ſorts, however, be potted in light, rich, loamy mould, if poſſible.

*Propagation.*

The propagation of all the ſorts is by ſeed, layers, and cuttings; but as they all grow freely by the two latter methods, raiſing from ſeed is almoſt unneceſſary, eſpecially to the two hardy varieties.

By Seed.—This is ſometimes practiſed for the green-houſe kinds; ſow the ſeed in autumn in pots, an inch deep, which in winter place in a frame, &c. to have ſhelter from froſt, but to enjoy the full air in open weather; and in ſpring plunge them in a moderate hot-bed, it will ſoon bring up the plants; when they are about three inches high, plant them in ſeparate pots, give water, and place them in the ſhade till freſh-rooted, and repeat the waterings as there ſhall be occaſion.

By Layers.—In ſpring lay a quantity of the young branches, by ſimple or common laying, they will readily emit roots, and be proper for tranſplanting in autumn.

By Cuttings.—In March or April plant cuttings of the young ſhoots of the green-houſe kinds in pots, and plunge them in a ſhady border, give water in hot weather, and they will readily grow; or if any time from April till the end of June, young cuttings are planted in a ſhady border, they will emit roots, and form plants fit to be potted in autumn; but cuttings of the two hardy varieties planted at almoſt any time of the year will readily grow, though from October till March is the beſt time, and they will form good plants by autumn following.

LYSIMACHIA, Looſe ſtrife.

The plants are hardy herbaceous perennials and biennials, &c. of upright growth, moſtly for the pleaſure-garden, riſing with erect ſtalks, from about half a yard to two or three feet high; garniſhed with narrow, entire leaves; and terminated by ſpikes and cluſters of monopetalous, rotated, five-parted, ſpreading flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is erect, acutely five-parted, and permanent. COROLLA, is monopetalous, rotaceous, and deeply divided into five flat, open-ſpreading ſegments. STAMINA, five ſubulate filaments, and acuminated antheræ. PISTILLUM, a round germen, filiforme ſtyle, and obtuſe ſtigma. PERICARPIUM, a globular, decemvalvular, unilocular capſule, having many angular ſeeds.

There are many ſpecies, but not more than three or four commonly retained in gardens, and thoſe moſtly perennials; all the ſorts having fibrated roots, ſending up ſtalks annually.

The ſpecies are;

1 LYSIMACHIA *Vulgaris.*

*Common Great Yellow Looſe-ſtrife.*] Hath a thick, creeping, widely-ſpreading, reddiſh root; upright firm ſtalks, three or four feet high; garniſhed with ſpear-ſhaped, pointed, ſeſſile leaves, by threes or fours; and each ſtalk dividing at top into ſeveral foot-ſtalks, each

each of thoſe terminated by a racemous cluſter of elegant yellow flowers; in June and July.

This inhabits ditch-ſides and moiſt places in many parts of England; but being a tall, fine ſhewy plant in bloom, it is admitted into large gardens for the variety of its flowers.

[2]LYSIMACHIA *Ciliata.*

*Ciliated Canadian Yellow Looſe-ſtrife.*] Hath a creeping, faſt-ſpreading root; many upright ſtalks, riſing two feet high; oval-lanceolate, ſmooth, oppoſite leaves, having ciliated foot-ſtalks; and from the upper axillas, long ſlender foot-ſtalks, each ſuſtaining one yellow flower; in June and July.

[3]LYSIMACHIA *Nummularia.*

*Nummularia, commonly called Yellow Money-wort, or Herb Two-pence.*] Hath a ſmall, creeping, ſpreading root; numerous, weak, trailing, rooting ſtalks; ſmall, nearly heart-ſhaped, ſmooth, oppoſite leaves; and from the axillas, long ſlender foot-ſtalks, each having a ſolitary yellow flower; in June and July.

It grows naturally in moiſt ſhady places in England, but is cultivated in many gardens for variety.

[4]LYSIMACHIA *Salicifolia, or Willow-leaved white Spaniſh Looſe-ſtrife*, is now removed to another genus; it grows three feet high, hav ſpear-ſhaped, narrow leaves, and the ſtalks terminated by long looſe ſpikes of fine white flowers; in June.

The flowers of all theſe plants are each of one rotaceous, or wheel-ſhaped, deeply-five-parted petal, are pretty numerous on each plant, tolerably conſpicuous, and are ſucceeded by ripe ſeeds in autumn, except the ciliated kind, which rarely produce ſeeds in England.

All the plants are perennial in root, and annual in ſtalk, and all of them multiply exceedingly by their creeping roots.

They are all very hardy, proſper in any common ſoil and ſituation in a garden, but delight moſt in ſomewhat ſhady moiſt places; they, however, may be planted any where to form a variety, and their roots will abide for years, and encreaſe greatly ſo as to ſend up many ſtalks, and exhibit a very ſhowy bloom.

All the ſorts here ſpecified are kept in moſt of the nurſery gardens for ſale.

They may be planted any time from October till March, and their culture is only the keeping them clear from weeds, and cutting down their decayed ſtalks in autumn, like other herbaceous perennials; and when the roots have ſpread too much, trim them in all around within due bounds.

*Propagation.*

The propagation of all the ſorts is effected abundantly by parting their roots any time, from the decay of the ſtalks in autumn until new ones begin to riſe in ſpring.

They may alſo be propagated by ſeed; ſowing them in autumn upon an eaſt border, and the plants will riſe plentifully in the following ſpring, ſome of which, when about three inches high, may be thinned out and planted in a ſhady border till autumn, when theſe, and all the others may be tranſplanted where they are to remain.

LYTHRUM, Willow-herb, *(Salicaria)* or Purple Looſe-ſtrife.

It furniſhes ſome hardy herbaceous, erect-growing, flowery perennials for ornamenting the pleaſure-garden compartments, riſing with upright ſtalks, from one to three or four feet high; adorned with cordate-lanceolate, and linear leaves; and terminated by long ſpikes of hexapetalous, very ornamental, purple flowers.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX, is monophyllous cylindric, having the brim indented in twelve parts alternately ſmaller. COROLLA, ſix oblong, obtuſe, patent petals, inſerted into the denticuli of the calix. STAMINA, twelve filaments, the upper ones the ſhorteſt, and aſſurgent antheræ. PISTILLUM, an oblong germen, ſubulate, declinated ſtyle, and riſing orbicular ſtigma. PERICARPIUM, an oblong, acuminated, unilocular, covered capſule, incloſing numerous ſmall ſeeds.

There are about nine or ten ſpecies, but not more than one in eſteem for our purpoſe, or that is commonly cultivated in the Engliſh gardens, which, however, comprehends ſome varieties.

LYTHRUM *Salicaria.*

*Salicaria, or Common Willow-herb.*] Hath a fibrated perennial root; upright, angular, purpliſh ſtalks, riſing three or four feet high; cordate-lanceolate leaves, oppoſite by pairs; and the ſtalk and branches terminated by long, erect ſpikes of reddiſh-purple, dodecandrous flowers; in July.

*Varieties.*] With round leaves—with long acute leaves—trifoliate leaved, growing three leaves

leaves at a joint——quadrifoliate, or four leaves at a joint—with quadrangular ſtalks—with hexangular ſtalks——with bright red flowers—purple-flowered—with verticillate, or whorled flowers.

This beautiful plant and varieties are reſidents of brook-ſides, and the like places in moſt parts of England, and are often diſregarded; they, however, merit culture in every curious garden for their ſtately growth and ornamental appearance of their elegant flowers, which adorn the top of the ſtalk in very long erect ſpikes.

They are all very hardy, perennial in root, and annual in ſtalk.

They may be employed to ornament any of the compartments of the pleaſure-ground, but are the moſt proſperous in moiſt, or ſomewhat ſhady ſituation, in which they will grow taller, ſtronger, produce larger ſpikes, and continue longer in beauty.

The plants may be eaſily obtained in the places of their natural growth, and are ſold at moſt of the nurſeries; and the ſeaſon for planting them is any time in open weather from October till March.

The propagation is by parting the roots, and by ſeed.

By parting the Roots.—Autumn, in October or November, is the beſt ſeaſon: the root may be divided into ſlips, preſerving fibres to each which if tolerable ſtrong, plant them at once where they are to remain; but if weak, ſet them in nurſery rows for a year.

By Seed —This is hardly worth practice, ſince the plants may be encreaſed with the utmoſt facility by roots; however the moſt ſucceſsful ſowing-ſeaſon is autumn, ſoon after the ſeeds are ripe, ſowing them in a bed or border of rich earth, and rake them in; they will riſe in ſpring; in ſummer, if too thick, thin out ſome and plant them in nurſery-rows till autumn; when both theſe, and thoſe remaining in the ſeed bed may be planted out for good, and will flower the next ſummer.

LUXURIANS, Luxuriant Plants, &c.—Theſe are ſuch that are greatly augmented in growth beyond their common natural ſtate; and it is obſervable of ſuch plants, &c. for the general part, that they rarely acquire that degree of perfection as plants of more moderate growth; and which ſtate of Luxuriance ſometimes happens through the exceſs of nouriſhment, and ſometimes by the nature of ſome particular plants.

But Luxuriance operates differently; it prevails ſometimes in the whole plant, ſometimes in particular parts of a plant, as in ſome of the ſhoots, and frequently in the flowers. We ſhall therefore conſider them under theſe three heads: 1. Luxuriant Plants—2. Luxuriant Shoots—3. Luxuriant Flowers.

'Luxuriant Plants and Trees.—Theſe as above obſerved, are ſuch as ſhoot conſiderably ſtronger than plants of the ſame ſpecies generally do, and is applicable both to herbaceous plants and trees, &c. and that very Luxuriant Plants and Trees never attain perfection ſo ſoon as moderate growers, as for example: moſt eſculent plants which ſhoot luxuriantly to leaves and ſtalks, &c. ſuch as cucumbers, melons, cabbage, cauliflowers, turneps, radiſhes, beans, peas, &c. never arrive ſo ſoon to perfection as thoſe of moderate growth, and ſuch plants as appear to be naturally of themſelves of that very Luxuriant nature are very improper to ſtand from which to ſave ſeed for propagation.

The ſame is alſo obſervable of fruit-trees; for ſuch as are very Luxuriant ſhooters are much longer before they attain a bearing ſtate, than thoſe of middling growth, nor do they ever bear ſo plentifully, nor the fruit attain ſuch perfection as in moderate-ſhooting trees: this Luxuriance happens ſometimes through exceſs of nouriſhment, as before obſerved, and ſometimes is the nature of the tree, and very frequently is acquired by unſkillful pruning, for it is very often the practice of bad pruners, that when wall or eſpalier trees aſſume a Luxuriant growth, to cut all the ſhoots ſhort, by which practice, inſtead of reducing the tree to a moderate ſtate of ſhooting, has increaſed its vigour, becauſe, as we have before occaſionally obſerved, the ſhortening of ſtrong ſhoots, promotes their throwing out ſtill ſtronger, and producing more abundant or ſuperfluous wood.

Therefore, in pruning very Luxuriant eſpalier and wall-fruit-trees, aſſiſt them in their own way, by training in plenty of ſhoots annually for a year or two, to divide the redundancy of ſap; that is, in training in the neceſſary ſupply of ſhoots, both in the ſummer and winter pruning, always leave them rather thicker than in the common practice, and moſtly at full length, unleſs it ſhall ſeem neceſſary to ſhorten any in ſome particular part of the tree, to force out a ſupply of wood to fill a vacancy; obſerving that ſome ſorts of fruit

fruit-trees ſhould never be ſhortened, except occaſionally for the purpoſe of procuring a ſupply of wood as juſt mentioned, which is particularly to be remarked in apples, pears, plums, cherries, figs, &c. for if ſhortening was to be practiſed to theſe ſorts, they would continue ſhooting every year ſo luxuriantly to wood, that they would never form themſelves into a proper bearing ſtate: even thoſe trees where ſhortening is neceſſarily practiſed in winter, to moſt of the annual ſupply of ſhoots, as in peaches, nectarines, &c. it, in caſes of Luxuriant growth, ſhould be very ſparingly performed, that is, not to cut any of the ſhoots very ſhort, and ſome of the moſt vigorous leave almoſt, or quite at full length.

This is the only method to reduce a Luxuriant tree to a moderate growth, and to a bearing ſtate; for by training the ſhoots thicker, and leaving them longer, and continuing it for a year or two, the redundant ſap conſequently having greater ſcope to divide itſelf, it cannot break out with that Luxuriance, as when it has not half the quantity of wood to ſupply with nouriſhment, as in the caſe of pruning ſhort; and by practiſing the above hints, a Luxuriant tree may in two years be brought to a moderate growth, and become a good bearer. See ESPALIERS, WALL-TREES, PRUNING, &c.

Luxuriance ſeldom occurs with any continuance in ſtandard-trees where permitted to take their natural growth, except ſometimes a ſtraggling ſhoot, which ſhould always be taken out by the rules mentioned in the following article.

[2]Luxuriant Shoots.—Theſe are applicable principally to trees and ſhrubs; more particularly to the fruit-tree kind, and eſpecially thoſe which undergo the diſcipline of an annual pruning; Luxuriant ſhoots, therefore, are frequently mentioned in the culture of the ſeveral ſorts of fruit-trees.

However, Luxuriant ſhoots are ſuch which ſhoot ſo vigorouſly in length and ſubſtance, as greatly to exceed the general growth of thoſe uſually produced on the ſame kind of plant or tree, and are ſometimes general, and ſometimes only happens to particular ſhoots in different parts of a tree, &c. and thoſe ſhoots denominated Luxuriant, are diſcoverable by their extraordinary length and thickneſs, and by their vigour of growth, which always greatly impoveriſhes the other more moderate ſhoots in their neighbourhood, and likewiſe the fruit, &c. and ſuch ſhoots very frequently occur in fruit-trees by the effects of pruning. When they are in general ſo, that is, all, or moſt of the ſhoots of an eſpalier or wall-tree are Luxuriant, manage them as above directed in treating of Luxuriant trees; but when luxuriance happens to particular ſhoots here and there in a fruit-tree, or indeed any other tree or ſhrub, under training, that ſuch ſhoots being both of ſuch a very Luxuriant nature as to draw the nouriſhment, or ſap, at the expence of all the adjacent moderate ſhoots on the ſame tree, and often by its vigorous irregular growth, cannot be trained with any degree of regularity; ſo that conſidering theſe diſadvantages of ſtraggling Luxuriant ſhoots, they ſhould for the moſt part, as ſoon as diſcoverable, in ſummer or winter pruning, be cut out, taking them off as cloſe as poſſible to the part of the branch from whence they originate, that no eye may be left to ſhoot again; unleſs, however, ſuch a ſhoot ſhall riſe in any part of a tree or ſhrub, where a further ſupply of wood may be requiſite, in which caſe it may be retained, and ſhortened as it ſhall ſeem convenient to force out a ſupply of more ſhoots laterally to fill the vacancy.

But, as above noticed, where a tree is wholly of a Luxuriant nature, producing almoſt in general Luxuriant ſhoots, leave them moderately thick, and train them along moſtly at full length, and by thus leaving a larger ſupply of wood for the ſap to divide itſelf, the tree in two ſeaſons will be reduced to a proper growth; when it may afterwards be managed according to the general rules exhibited under its reſpective genera.

[3]Luxuriant Flowers.—All double flowers may be conſidered as Luxuriant, eſpecially ſuch which have either the cup or corolla multiplied, or ſo augmented in numbers inward, as to exclude ſome part of the fructification, for the ſame is obſervable in flowers as in eſculent plants and fruit-trees, that Luxuriance tends to their imperfection in the original intention of nature; the flower being deſigned for perfecting the fruit and ſeed; but when the petals are multiplied to the diminution of the ſtamina, &c. ſo that no impregnation enſues, no fruit or ſeed can be produced, conſequently, by the Luxuriant augmentation of the corolla, plants often become barren.

Luxuriance in flowers, however, conſiſts of three modifications. Firſt, ſuch as have the petals multiplied, yet do not entirely

exclude the ſtamina. Secondly, ſuch in which, by the multiplicity of the petals, all the ſtamina are excluded, ſo that no impregnation can be effected. Thirdly, ſuch flowers as produce one out of another, as in the prolific anemone, &c.

But Luxuriant flowers which do not exclude all their ſtamina, are capable of impregnation, and conſequently produce ſeed.

The higheſt degree of luxuriance is often obſervable in carnations, anemones, ranunculus, poppy, lychnis, peony, narciſſus, violet, &c.

---

# M.

MAGNOLIA, *(Magnolia)* Laurel-leaved Tulip-tree.

This genus conſiſts of moſt elegant ever-green and deciduous trees of North America, for ornamental plantations and the green-houſe; riſing with upright trunks, dividing upward into fine regular heads; adorned with noble large, oblong, ſimple foliage, and large novem-petalous flowers of remarkable fragrance; which, in America, their native ſoil, are ſucceeded by a large egg-ſhaped ſtrobilus, ſcaley fruit, compoſed of ſeveral compreſſed, roundiſh, unilocular capſules, containing large pendulous ſeeds, i. e. that being diſcharged from their departments, hang by long threads in a ſingularly curious manner; but the fruit never attains perfection in England, and is not of the eatable kind.

Claſs and order, *Polyandria Polygamia.*

*Characters.*] CALIX, is three petaliforme, oval, concave, deciduous leaves. COROLLA, nine oblong, concave, obtuſe petals, narrow at the baſe. STAMINA, numerous ſhort filaments inſerted into the baſe of the piſtillum, and linear antheræ attached to the ſides of the filamentum. PISTILLUM, numerous oblong-oval germina, very ſhort, recurved, contorted ſtyles, and longitudinal hairy ſtigmas. PERICARPIUM, an oval ſtrobilus, or cone, compoſed of compreſſed, roundiſh, almoſt imbricated, cluſtered, unilocular, bivalvular capſules, each containing one roundiſh, baccated ſeed, hanging by ſlender threads from the ſcales of the ſtrobilus.

There are but four ſpecies, all of the tree kind, one of them an ever-green, and one of the moſt beautiful in the world; the other three are deciduous, and alſo very beautiful. All the ſorts, though originally of American growth, proſper in our gardens in the full ground all the year; they, however, being ſomewhat tender while young, require protection from froſt, but afterwards may be turned out into the principal ſhrubbery plantations in the moſt conſpicuous parts, where they will appear exceedingly ornamental in their fine luxuriant foliage, in ſome reſembling the noble leaves of laurel, but much larger, as in ſome ſorts they are near a foot long and almoſt half as broad.

*Ever-green Kind.*

This is a noble tree, very diſtinguiſhable from all others, yet known by its ſingularly large, and beautiful ſhining leaves.

MAGNOLIA *Grandiflora.*

*Greater Grandiflorous Ever-green Magnolia.*] Riſeth with an upright ſtem, branching out upward into a regular head, ſeventy or eighty feet high; garniſhed with very large, ſpear-ſhaped, thick, firm, cloſe-ſitting, ever-green leaves, eight or ten inches long, and near half as broad, of a ſhining green above, and paler underneath; and from the ends of the branches, large pure-white flowers, of nine or ten broad-ſpreading petals; ſucceeded by oval, cone-like fruit, which never ripen in England.

*Variety.*] With leaves of a ſhining-green above, and of a ruſty colour underneath.

*Deciduous*

*Deciduous Kinds.*

Theſe ſorts though deciduous are moſt beautiful trees, when in foliage, and elegant furniture for the beſt ſhrubberies.

[2]MAGNOLIA *Glauca.*

*Glaucous-leaved Deciduous Magnolia.*] Riſes with an upright ſlender ſtem, branching ten or fifteen feet high, having a ſmooth white bark; oval oblong, deciduous leaves, three or four inches long, of a glaucous hoary colour underneath; and from the extremity of the branches white flowers, ſucceeded by conic ſtrobilus fruit, which never ripens in England.

This ſort is remarkable for retaining its leaves great part of winter, appearing like an ever-green.

[3]MAGNOLIA *Tripetala.*

*Tripetalate Magnolia, or Umbrella-tree.*] Riſes with an upright ſtem, branching about twenty feet high; very large lanceolate leaves, diſpoſed in circular rays horizontally, in form of an umbrella; and large white flowers, having the outer petals dependent.

The name Umbrella-tree is derived from the diſpoſition of its admirable large foliage, ſo as to reſemble the form of an umbrella.

[4]MAGNOLIA *Acuminata.*

*Acuminate Long-leaved Deciduous Magnolia.*] Riſes with an upright ſtem, branching fifteen or twenty feet high, having a ſmooth light bark; large oval-oblong, acuminate-pointed leaves, eight or ten inches long, and half as broad; and white flowers, having from nine to twelve petals; ſucceeded by conical fruit, not ripening in England.

All theſe four ſpecies of Magnolia are admirable fine ornaments for the principal ſhrubbery compartments; the grandiflorous kind alſo for the green-houſe, which is the moſt beautiful of all the ſorts; but all of them are remarkably ornamental in their large elegant foliage, which are univerſally ſimple, entire, and almoſt ſeſſile; and all the ſpecies after having acquired ſome conſiderable age and ſize, produce flowers here annually in June or July, are large, of a ſnowy white, and remarkable fragrance; and ſometimes on old trees are ſucceeded by the formation of fruit, but it never acquires maturity in this country.

The flowers of all the ſorts in their characteriſtic ſtate, conſiſt each of nine oblong obtuſe petals, and numerous filaments and germina, &c. ſee the *Characters.*

In the American woods where theſe trees grow naturally in great abundance, the flowers are numerous on each tree, continue a long time in bloom, and perfume the whole woods with their agreeable odour.

All the four ſpecies are of ſomewhat tender temperature, and liable to injury from froſt while young, the *Magnolia Grandiflora* moſt of all; but none of them, however, ſo tender but that they may be naturalized to this climate, after having occaſional protection in winter during their infant ſtate, by keeping them in pots three, four, or five years, in order to move to ſhelter of a frame or green-houſe in froſty weather; obſerving that the grandiflorous kind need this care the longeſt of any, the ſeedling plants of which generally requiring to be five or ſix years old before they can be truſted in the full ground finally; the other three ſorts, as they drop their leaves in autumn, their ſhoots become more hardened, and not ſo ſubject to the rigours of froſt, will generally ſucceed in the open ground after the ſecond or third winter; but all the ſorts ſhould be gradually hardened by expoſing them conſtantly to the full air ſummer and winter, in all mild or open weather, and only give ſhelter from froſt; and when tranſplanted into the full ground, it ſhould be done in March; but ſome of the ever-green *Magnolia* ſhould alſo be retained in pots as green-houſe plants.

The grandiflorous ever-green Magnolia is one of the moſt beautiful trees in nature, both in the procerity and grandeur of its growth; and in its luxuriant noble leaves, which renders the tree ſingularly conſpicuous and diſtinguiſhable, at all ſeaſons, and may be conſidered the fineſt ornamental ever-green yet known, both for the ſhrubbery and green-houſe. Remarking, as already obſerved, that as the trees of this ſort are impatient of froſt whilſt young, they ſhould be kept in pots a few years, in order to have ſhelter of a garden-frame or green-houſe occaſionally in winter, when froſts prevail; and even when thoſe intended for the ſhrubbery are turned out into the full ground, it is proper alſo to erect a ſort of frame-work of pliable poles, &c. archwiſe over each plant, in November, for the ſupport of a covering of mats in rigorous weather, for a few winters: it is likewiſe proper, as before noticed, to retain ſome in pots, to be managed as green-houſe plants; and if thoſe in the full ground ſhould ſuffer by the froſt, theſe will remain unhurt, and

be as a reſerve; obſerve, however, with reſpect to thoſe in the full ground, to endeavour to naturalize them gradually as much as poſſible, to ſtand our ordinary winters without covering, which undoubtedly may in time be effected, eſpecially thoſe plant raiſed by layers and cuttings from plants, which have been of ſome years ſtanding in the open ground.

The deciduous *Magnolias* are alſo remarkably ornamental trees, and ought to be introduced into every curious collection in ſhrubberies, where by their admirable fine foliage, they will exhibit an elegant variety. All theſe deciduous ſorts after having occaſional ſhelter two or three winters in their minor ſtate, will ſucceed tolerably in the open ground all the year without covering.

All the ſpecies, both ever-green and deciduous, are cultivated in the nurſeries for ſale, of which the firſt ſort, as being the moſt beautiful, and requiring more care in its culture, is generally pretty high rated.

The beſt ſeaſon for planting all the ſorts is in February and March, before they begin to make an effort for ſhooting, though as thoſe ſorts which are in pots may be turned out with the ball of earth about their roots, ſo as ſcarce to feel their removal, they may be occaſionally tranſplanted in October or begining of November; I, however, ſhould gegenerally prefer the ſpring-planting that they may be both firmly rooted, and inured to the ſoil, ſituation, and full air before winter.

Obſerve, that in the diſpoſition of all the ſorts in the ſhrubbery, as they are rather of a tender nature in their younger growth, it is proper to allot them a ſheltered ſunny ſituation, and dry ſoil; and all of them ſhould be ſtationed in the moſt conſpicuous point of view; and not too cloſely crowded with ſhrubs of inferior merit; they have alſo an admirable effect diſpoſed ſingly in different parts, particularly in open ſpaces of graſs-ground in the internal parts of the ſhrubbery plantations, the *Magnolia Grandiflora* in particular appear beautiful in this mode of diſpoſition; obſerving of this ſort, that whereſoever ſtationed, to allow it the occaſional ſhelter of an awning of mats in froſty weather, as before noticed.

### *Propagation, &c. of all the Sorts.*

The propagation of all the ſorts is by ſeed, alſo by layers and cuttings.

By Seed.—This is received annually from America, preſerved in ſand, and commonly arrives here early in ſpring, which ſhould be ſowed as ſoon after as poſſible in pots of light rich earth, half an inch deep; and the pots then either plunged in a moderate hot-bed, juſt to bring up the plants an inch or two high, or may be plunged in common earth under a warm wall or hedge, or in a frame, in the full ſun till the middle or latter end of April, then replunged in an eaſterly border open to the morning ſun; giving moderate ſprinklings of water in dry weather, and the plants will riſe the ſame year, thoſe having aid of a hot-bed, probably in April, and the others in May; obſerving to inure thoſe in the hot-bed timely to the full air. All ſummer let the ſeedlings raiſed by either method be very regularly ſupplied with water; at the approach of winter remove the pots into a green-houſe, or rather under a garden-frame, there ſheltered from froſt all winter, but indulge them with the open air all mild weather. In March if the pots are plunged in a bark hot-bed, under a frame two or three months, it will forward the ſeedlings greatly, being careful to give water, and harden them to the open air gradually, ſo as to be removed into it fully in June, to remain till October, then allow them ſhelter in winter as aforeſaid. Spring following plant them into ſeparate pots, and plunge them into a hot-bed as above, to ſet them forward, giving water, occaſional ſhade, and the benefit of the free air; and in June remove the pots to a ſhady border for the remainder of the ſummer; in winter give them ſhelter, as before, from ſevere froſt, but to have the full air in all open weather. The ſame care may be proper for two or three winters, when ſome of them may be turned out of the pots with the ball about their roots, into the full ground in a warm place, eſpecially the deciduous kinds; but the grandiflorous or ever-green ſort, being tender, muſt not be too ſoon committed to the winter's cold, they ſhould, therefore, be continued in occaſional ſhelter, as above, four or five years at leaſt, and when turned out into the open ground, it is proper to mat them occaſionally, as already hinted, in ſevere winters; ſtill retaining ſome in pots to be managed as green-houſe plants.

By Layers.—All the ſorts may alſo be propagated by this method, which may be performed in autumn or ſpring: chuſe the young pliable ſhoots, give them a gentle twiſt, or a

ſlit

ſlit in the part to be layed, and lay them in the uſual method: ſome will be rooted in one year, others probably not in leſs than two; then in March take them off and plant each in a pot, plunge them in a moderate hot-bed for a month or two to ſet them a-going freely at firſt, and they will form good ſtrong plants by autumn, allowing them ſhelter in winter for a year or two, then may be tranſplanted into the full ground.

By Cuttings.—This may be effected by aid of a bark-bed, particularly that in the ſtove, &c. In March or April plant ſome ſhort young ſhoots of the preceding year in pots, plunge them to the rims in the hot-bed, giving water and occaſional ſhade, many of them will be rooted the ſame year, when they muſt be inured by degrees to the open air, afterwards managed as the layers.

MALPIGHIA, Barbadoes Cherry.

The plants are ſhrubby ever-greens of the warm parts of America, &c. retained here in ſtoves for variety; riſing with branchy ſtems, from eight or ten to fifteen or twenty feet high, ornamented with oval and lanceolate entire leaves, and large pentapetalous flower, ſucceeded by baccaceous, cherry-ſhaped, red, eatable fruit.

Claſs and order, *Decandria Trigynia.*

*Characters.*] CALIX, is ſmall, five-leaved, connivent and permanent. COROLLA, five reniforme, concave, ſpreading petals, having long narrow ungues. STAMINA, ten broadiſh, ſubulate, erect filaments, and heart-ſhaped antheræ. PISTILLUM, a roundiſh germen, three ſlender ſtyles, and obtuſe ſtigmas. PERICARPIUM, a large globular, furrowed, unilocular berry, containing three angular, rough, ſtoney ſeeds.

There are eight or nine ſpecies, thoſe of them chiefly found in the Engliſh gardens are;

[5]MALPIGHIA *Glabra.*

*Glabrous-leaved Malpighia, or Common Barbadoes Cherry.*] Riſes with a ſhrubby, erect, ſlender ſtem, branching fifteen or twenty feet high; oval, entire, very ſmooth, oppoſite leaves; and from the ſides and ends of the branches long foot-ſtalks, each ſuſtaining an umbellate cluſter of roſe-coloured flowers; ſucceeded by roundiſh, baccaceous, red, cherry-like fruit.

[2]MALPIGHIA *Punicifolia.*

*Pomegranate-leaved Malpighia.*] Riſeth with a ſhrubby erect ſtem, branching diffuſely eight or ten feet high; oval, entire, ſmooth, oppoſite leaves; and from the ſides and ends of the branches ſhortiſh foot-ſtalks, each ſuſtaining one pale-red flower; ſucceeded by round baccaceous fruit.

[3]MALPIGHIA *Urens.*

*Stinging Malpighia.*] Riſes with a ſhrubby robuſt ſtem, branching fifteen or eighteen feet high; oblong-oval leaves, covered underneath with briſtly, decumbent, ſtinging hairs; and from the ſides of the branches aggregate foot-ſtalks, each ſuſtaining one purple flower; ſucceeded by oval, red fruit.

All theſe ſhrubs retain their leaves the year round; and begin flowering here about the end of autumn, continuing in conſtant ſucceſſion till ſpring, exhibiting a fine variety in the ſtove, where they are frequently ſucceeded by ripe fruit, which in moſt ſorts is of the ſize and ſhape of a ſmall cherry; is of an acid palatable flavour, and in the Weſt Indies, where the ſhrubs grow naturally in vaſt plenty, the fruit is eaten by the inhabitants inſtead of cherries; but thoſe of the firſt ſort are in moſt eſteem.

As the plants are natives of hot countries, they require a hot-houſe here, ſo muſt be always be kept in pots of rich earth, and retained in the ſtove, except about a month or two in the heat of ſummer, when they may be placed abroad; obſerving to ſupply them duly with water all the year.

Their propagation is by ſeed; ſow it in ſpring, in pots of rich earth, and plunge them in a hot-bed; and when the plants are three or four inches high, prick them in a ſeparate ſmall pots, give water, and plunge them in the bark-bed in the ſtove, where let them remain a year or two, then may be placed in any part of this department.

MALVA, Mallow.

This genus conſiſts of herbaceous perennials, biennials, and annuals, for medical uſes, and for ornament in gardens; and a ſhrubby plant for the green-houſe, riſing moſtly with erect ſtalks, from about half a yard to ten or twelve feet high, in different ſorts; garniſhed with large, roundiſh, lobated leaves, and quinquepetalous flowers.

Claſs and order, *Monadelphia Polyandria.*

*Characters.*] CALIX, is double, the exterior part is of three heart-ſhaped leaves, the interior is monophyllous and five-parted at the brim. COROLLA, is five obcordate plane petals, coaleſcing at their baſe. STAMINA, numerous monodelphous filaments, inſerted into

into the corolla, and kidney-ſhaped antheræ. PISTILLUM, an orbicular germen, ſhort cylindric ſtyle, and many briſtly ſtigmas. PERICARPIUM, a round depreſſed head, compoſed of numerous arilli, or ſeed covers, each having one kidney-ſhaped ſeed.

There are upwards of twenty different ſpecies, but not more than four or five generally known here; three or four of which are hardy herbaceous plants, and one ſhrubby exotic for the green-houſe.

*Hardy Herbaceous Kinds.*

The firſt and ſecond of theſe kinds, is the common Mallows of the field, for medicinal purpoſes, the others are ſometimes kept in gardens for variety.

[1]MALVA, *Sylveſtris (perennial).*

*Common Wild Upright Mallow.*] Hath a long, fibrated, tough, deeply-ſtriking root; upright ſtalks, two or three feet high; garniſhed with roundiſh ſeven-lobed leaves, having the lobes acute; and many reddiſh-purflowers from the ſides of the ſtalks.

*Varieties.*] With jagged leaves——with white flowers—with blue flowers.

This is perennial in root, but annual in ſtalk, grows wild every where: its root, leaves, flowers, and ſeed, are all medicinal.

[2]MALVA *Rotundifolia.*

*Round-leaved Proſtrate Wild Mallow.*] Hath proſtrate, or declinated ſtalks; roundiſh cordate, obſoletely five-lobed leaves, and purpliſh flowers.

This alſo grows wild, as the former.

[3]MALVA *Alcea (Biennial).*

*Malva Alcea, or Vervain Mallow.*] Hath long fibrated roots; upright ſtalks, branching two feet high; garniſhed with large, many-parted, roughiſh leaves; and large bright-red flowers from the ſides of the ſtalks.

*Varieties.*] With downy leaves——with white flowers

This ſort and varieties are all biennial, and grow wild in ſome parts of England.

[4]MALVA *Moſchata.*

*Malva Moſchata, or Jagged-leaved Vervain Mallow.*] Hath long fibrated roots; reniforme, deeply-cut, radical leaves; upright ſtalks, branching about two feet high; garniſhed with five-parted leaves, having the lobes pinnated into many parts; and large red flowers.

*Varieties.*] With roundiſh leaves—curled leaves—with white flowers.

They are all biennial, and grow wild here in ſome parts.

[5]MALVA *Criſpa (annual).*

*Curled-leaved Syrian Mallow.*] Riſes with an upright ſtrong thick ſtalk, ſix or eight feet high; cloſely garniſhed with large, angular, curled leaves, having the edges curiouſly furbelowed; and from the axillas glomerated cluſters of reddiſh flowers.

This is an annual of Syria, but hath been long retained in our gardens for ornament.

All the above five herbaceous Mallows flower in June, July, and Auguſt, ſucceeded by great plenty of ſeed in autumn.

*Shrubby Green-houſe Kinds.*

[6]MALVA *Capenſis.*

*Cape Shrubby Mallow.*] Riſes with a tree-like, erect, thick, durable ſtem, ten or twelve feet high, branching out laterally the whole length, the branches numerous and hairy; garniſhed with ſubcordate, laciniated, ſmooth leaves; and from the ſides of the branches, large deep-red flowers; appearing great part of the year.

*Variety.*] Gooſeberry-leaved Cape Shrubby Mallow.

With reſpect to the merit of all theſe ſix ſpecies of Malva, take the following hints.

As to the five herbaceous kinds; the two firſt of them are exceedingly uſeful in medicine, particularly the *Malva Sylveſtris*; but they both growing wild all over England, and being moſt troubleſome weeds, are rarely admitted into the gardens; but the third and fourth ſorts, although they grow naturally alſo in ſome parts of England, are introduced into many gardens for ornament and variety, and they effect a very conſpicuous diverſity in aſſemblage with other plants of ſimilar growth; and the *Malva Criſpa* is likewiſe, very proper to increaſe the variety in large pleaſure-grounds, which it effects moſt agreeably in the procerity of its growth and beautifully furbelowed leaves.

And the Cape Shrubby Mallow is very ornametal, and green all the year, but being a native of Africa, requires ſhelter in winter, therefore muſt be kept in pots of good earth, and placed in the green houſe collection.

*Propagation.*

All the herbaceous kinds are raiſed plentifully from ſeed. Sow them in ſpring, in a bed

bed or border of any common earth, either in patches where they are deſigned to flower, half an inch deep, or in a bed, and raked in, for tranſplantation, which ſhould be performed when the plants are three or four inches high; though I ſhould adviſe the annual ſort in particular to be ſowed in patches where the plants are to remain: ſeveral ſeeds in each patch, but leave only two or three of the beſt plants to grow to perfection.

The ſhrubby kind is alſo eaſily raiſed from ſeed in ſpring, but ſhould have the aid of a hot-bed, and when the plants are about three inches high, plant them in ſmall pots, harden them by degrees to full air, afterwards manage them as other green exotics.

MAMMEA, Mammee-tree.

There are but two ſpecies, both large evergreen trees of the hot parts of America and Aſia, and retained here in hot-houſes for variety; both of them adorned with large oval-oblong ſtiff leaves, and large quadripetalous, flowers, ſucceeded by large round eatable fruit, of a moſt exquiſitely rich flavour.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, is monophyllous, two-parted and deciduous. COROLLA, four large concave ſpreading petals. STAMINA, numerous ſhort filaments, and oblong antheræ. PISTILLUM, a roundiſh depreſſed germen, cylindric ſtyle, and a capitated permanent ſtigma. PERICARPIUM, a large ſpherical, baccaceous, fleſhy, unilocular fruit, terminated by the ſtyle, and contains four ſuboval rough ſeeds.

The ſpecies are:

[1]MAMMEA *Americana.*

*American Mammee-tree.*] Riſes with an upright, robuſt, rough trunk, branching ſixty or ſeventy feet high; large, oval-oblong, firm, ſplendid leaves, and having the ſtamina ſhorter than the corolla; and large round fruit.

[2]MAMMEA *Aſiatica.*

*Aſiatic Mammee-tree.*] Riſes with an upright large ſtem, branching fifty or ſixty feet high; covered with a cinereous, furrowed bark; large oval-oblong leaves; flowers, having the ſtamina longer than the corolla; and large tetragonous fruit.

Both theſe trees in their native ſoil produce abundance of fine fruit, as large as Catharine peaches, of a yellowiſh-green colour, and ſaid to be of a delicate flavour.

The firſt ſort grows in great plenty in the Weſt Indies; and the other in Java.

In this country they require to be continued conſtantly in the ſtove, ſo muſt be kept always in pots, and placed in that conſervatory, where they will cauſe a fine variety all the year with their large ſplendid foliage.

Their propagation is by ſeed, which arrives from America, &c. in ſpring. Sow it in ſmall pots of light rich earth, and plunge them in the bark-bed, where they will ſoon come up; give gentle waterings, and about Auguſt tranſplant them into ſeparate pots a ſize larger, plunging them in the bark bed, and give ſhade and water till freſh-rooted.

MANURE. This compriſes all ſorts of dungs, compoſts, and other materials proper for the improvement of land. See COMPOSTS, DUNG, &c.

Manure, therefore, is neceſſary to all ſoils, to repair them when exhauſted by the growth of vegetables, and to cure the defects of ſoils naturally bad, ſuch as to enrich and fertilize very poor land; to render very ſtrong or ſtubborn land more light, looſe, and pliable; and to render very light, looſe, dry ſoils more compact and moiſt; and wet land drier, &c. ſtrong moiſt land is the moſt improved by light manures, to open and looſen it; very light land by the more heavy and moiſt ſort of Manure; and wet land by dry light compoſts; ſome ſoils require Manure annually, others but once in two or three years; all of which in reſpect to garden-culture is fully exp'ained under the article DUNGS, &c.

The proper Manure for garden-ground being fully exhibited under the article DUNGS, it is needleſs to repeat it here.

But for corn-fields, &c. various ſorts of Manure are occaſionally uſed, according to the nature of the ſoil, and what different countries afford, as for inſtance:

All ſorts of horſe dung, neats dung, hogs-dung, farm-yard mulch; or a mixture of all or any of thoſe together, ſuits almoſt all ſorts of land; or a compoſt of any or all of thoſe, and chalk, lime, earth, mud of ponds and ditches, cleanſings of ſtreets, aſhes, rotten tanner's bark, rotten wood, and ſaw duſt, rotten vegetables, &c. or ſuch of any of theſe materials as can be had, and formed into a compoſt-heap to rot together, make a good Manure, both for corn and graſs-land.

For the method of making compoſt heaps, ſee COMPOST.

Rotten tanner's-bark alone, or in compoſt, is good Manure for ſtrong, cold, corn-land; and

and will alſo ſuit graſs, if applied the beginning of winter, for the rains to waſh it into the ground.

Rotten wood, and rotten ſaw-duſt, is very proper for ſtrong land.

Rotten vegetables, ſuch as all ſorts of weeds, and the refuſe of kitchen-gardens, &c. laid in heaps, and if mixed with mud or any earthy ſubſtance, and the whole lie to rot, they will make a tolerable good Manure for corn-land.

Green fern mowed down and laid in heaps to rot, is alſo uſed as Manure.

Marle, chalk, lime, &c. properly prepared, either alone, or in compoſt, are greatly uſed in many places as a dreſſing for corn-land.

Sea-ſand and ſhells, &c. being full of ſalts, are ſometimes uſed as Manure for ſtrong clayey and ſtubborn loamy ſoils.

Sea-weed is likewiſe employed as Manure, and, being full of ſalts, greatly improves corn-land.

Aſhes of all ſorts prove excellent Manure, eſpecially to all ſtrong cold or moiſt land; but coal aſhes are ſuperior to thoſe of wood, or of any other kind of vegetables; the farmers in the counties round London have experienced this, and they fetch them from that city by cart and waggon-loads, twenty or thirty miles diſtance; for in London they in general uſing coal-fuel, prodigious quantities of aſhes are daily made, and collected in carts and carried to the aſh-hills in the environs of the city; where numbers of people are employed in ſifting them, and ſell the ſiftings by the ſack or load to the farmers for Manure; alſo to the brick-makers for tempering their loam or brick-earth.

Bones of animals are alſo uſed as Manure for ploughed-land, where they are to be had in due quantities, as about London and other great cities.

Soot is alſo uſed as Manure to ſprinkle thinly over corn-land.

Malt duſt, containing a natural heat and ſweetneſs, proves an eligible Manure to moſt ſorts of land, but more particularly to ſtubborn, clayey, and ſour harſh ſoils.

Cleanſings of ſtreets laid in compoſt-heaps with horſe-dung, &c. makes excellent Manure both for corn and graſs-ground.

All Manure for ploughed or digged-land, ſhould be applied at the time the ground is to be tilled, and not ſpread about any long time before it is ploughed in, eſpecially in hot dry weather, which would exhauſt the ſalts, and other enriching particles; obſerving, however, where any hard ſubſtances, as marle, ſhells, &c. are uſed for Manure, it is proper to ſpread them abroad ſome conſiderable time, expoſed to the ſun, rains, and froſt, to pulverize, before they are ploughed into the ground.

The Manuring graſs-land ſhould generally be performed in autumn, about Michaelmas, or a little before or after, and not in the heat of ſummer, as is often practiſed, whereby the ſun's heat greatly exhauſts its moiſture and goodneſs; but when done in autumn, the rain ſoon waſhes the enriching particles into the ground, to the great benefit of the graſs, and encreaſe of the future crop.

MARANTA, Indian Arrow-root.

It conſiſts of two herbaceous perennial exotics of the Indies, kept here in hot-houſes for curioſity; have thick, knotty, creeping roots, crowned with long, broad, arundenaceous leaves, ending in points, and upright ſtalks, half a yard high, terminated by bunches of monopetalous, ringent, five-parted flowers.

Claſs and order, *Monandria Monogynia.*

*Characters.*] CALIX, is three ſpear-ſhaped leaves placed on the germen. COROLLA, is monopetalous and ringent, has an oblong, compreſſed, oblique, inflexed tube, the limb divided into ſix parts, the ſide ones large and repreſent a lower-lip. STAMINA, one membraneous filament, reſembling a ſegment of a corolla, and linear antheræ attached to the border. PISTILLUM, a roundiſh germen under the calix, ſimple ſtyle, and obſoletely trigonous ſtigma. PERICARPIUM, a roundiſh trigonous trivalvular capſule, and one oval hard ſeed.

The ſpecies are;

[1]MARANTA *Arundinacea.*

*Arundinaceous Maranta.*] Hath a thick, knotty, creeping, fleſhy root; crowned by long, broad-baſed, arundenaceous, or reed-like leaves, diminiſhing upward to a point; amidſt them upright, divided, branchy ſtalks, two feet high, terminated by bunches of white flowers.

[2]MARANTA *Galanga.*

*Galanga, or Indian Arrow-root.*] Hath a thick, creeping, fleſhy, juicy root; crowned by many ſmooth leaves, ſix or ſeven inches long; amidſt them upright, ſimple, or undivided ſtalks, half a yard high, terminated by looſe bunches of ſmall white flowers.

Both

Both the ſorts flower here annually in June and July, each flower conſiſting of one ringent, or grinning petal, ſix-parted at top. See the *Characters*.

The plants are perennial in root, but annual in leaf and ſtalk, ſometimes, however, the leaves of the ſecond ſort abide moſt part of the year.

Both the ſpecies being natives of the hot regions of the Indies, in this country they muſt be potted, and always kept in the hot-houſe, plunging them moſtly in the bark-bed, and refreſh them with moderate waterings, but more frequent when in a growing ſtate, and ſhift them into larger pots occaſionally.

Their propagation is by parting the roots, and ſpring is the proper ſeaſon, juſt before they begin to ſhoot; planting them in pots of light rich earth, and plunge them in the bark bed.

In America the roots of the *Galanga* being uſed by the Indians to extract the poiſon communicated by their poiſoned arrows, it derived the name of Arrow-root.

MARLE, a kind of clayey, or ſtrong earthy ſubſtance, of a chalky nature, generally placed deep in the earth, and is of a fertile quality, by its ſalt and oily properties, and is uſed to manure land. See MANURE.

Marle is of different natures in different parts.

Some is nearly of the nature of fullers earth, and is of a fat enriching quality, and of which there is blue, grey, yellow, and red coloured; the blue is eſteemed to be the beſt.

Some is a kind of ſoft ſtone, or rather of a flatey nature, of a blueiſh and grey colour, and is called ſtone or ſlate Marle, found commonly near river-ſides, and ſides of hills, &c. and though hard when dug, eaſily diſſolves by rain and froſt.

Clay Marle reſembles a fat ſort of clay or loam, and is ſometimes mixed with chalk ſtones.

Spitting or delving marle, is of a compact, ſtrong, fat temperature, generally of a brown colour; and is met with in the ſides of hills, and in ſome wet boggy grounds.

There are ſome other ſorts of Marle of leſs note, which lie very deep, and not ſo eaſily obtained.

The ſure ſign of the goodneſs of Marle is when it readily diſſolves by wet or froſt.

All the ſorts of Marle are accounted good manure for improving light, looſe, ſandy land in particular, eſpecially the fat kinds of Marle; though it may be applied with ſucceſs to moſt ſorts of land, obſerving, however, to uſe it more ſparingly on ſtrong ſoils, leſt it bind it too cloſe; but to ſandy ground there can be no danger, and proves one of the beſt dreſſings for ſuch kind of land.

It is commonly laid upon the land as it is taken from the pits; but ſome burn it, when one load will go as far as three or four.

MARTYNIA, *Martynia*.

This genus conſiſts of two tender herbaceous flowery plants of South America, an annual and a perennial, both for the hot-houſe; riſing with erect ſtalks, garniſhed with oblong ſimple leaves, and terminated by ſhort ſpikes of large monopetalous bell-ſhaped flowers.

Claſs and order, *Didynamia Angioſpermia*.

*Characters.*] CALIX, is five-parted and withering. COROLLA, is monopetalous, bell-ſhaped, the tube ventricoſe, and the limb five-parted at top. STAMINA, two long and two ſhort incurved filaments, and connivent connected antheræ. PISTILLUM, an oblong germen, ſimple ſtyle, and bilobed ſtigma. PERICARPIUM, an oblong, quadrangular, quinquelocular capſule, opening in two at top, and having oblong ſeeds.

The ſpecies are;

[1]MARTYNIA *Annua*.

*Annual Martinia.*] Riſes with an upright, robuſt, hairy, branching ſtalk, three feet high; garniſhed with large oval-oblong, angulated, entire, hairy, viſcous leaves; and from the forks of the ſtalk, and ends of the branches, ſhort ſpikes of large reddiſh-purple flowers.

[2]MARTYNIA *Perennis*.

*Perennial Martynia.*] Hath thick knotty roots, ſending up ſeveral robuſt, ſimple, ſucculent, purpliſh ſtalks, a foot high; garniſhed with oblong, ſerrated, thick, cloſe-ſitting leaves; and terminated by ſhort ſpikes of blue flowers.

Both the ſpecies flower here in July and Auguſt, and are very ornamental; each flower is of one bell-ſhaped petal, ſucceeded by large, oblong, thick, tough capſules, which in the annual ſort ripen here in autumn, but the ſecond ſeldom ripen ſeeds in England.

Theſe two plants being inhabitants of the hotteſt parts of the world, will not ſucceed here without artificial heat, ſo require the aid of a hot-houſe.

In reſpect to their duration, the firſt continues but one ſeaſon, the other ſeveral years by the root, but the ſtalks decay annually in autumn.

The firſt ſort is propagated by ſeed, ſowed in pots in ſpring, and plunge them in a hot-bed, or in the bark-bed in the ſtove, giving ſprinklings of water; and when the plants are two or three inches high, plant them out in ſeparate ſmall pots, which plunge alſo in the bark-bed, allowing them ſhade and water; and when they are a little advanced in growth, ſhift them into larger pots, managing them as above.

The ſecond ſort is propagated by dividing the roots in ſpring, planting each off-ſet in a pot of rich mould, and plunged in the bark-bed.

It may alſo be encreaſed by cuttings or the ſtalks planted in pots, and plunged in the bark-bed.

MAS *Planta*, a Male Plant; a dioecious plant, which produces male flowers only. See the claſs *Dioecia*.

All the plants of this kind belong to the claſs *Dioecia*, and the plants of which have Male and female flowers always on ſeparate roots, i. e. the Males on one plant, and the females on another; ſo that the plants furniſhing the Male bloſſoms, are properly Male Plants, and thoſe producing female flowers, are termed female plants. See FEMINEUS *Planta*.

Of this kind are ſpinach, hemp, *Myrica Meniſpermum*, and many others.

Male Plants never produce ſeed; which is produced only from the females; but both Male and female plants riſe from the ſame ſeed.

MASCULUS *Flos*, a Male Flower; a flower of the claſſes *Dioecia* and *Monoecia*, which is furniſhed with ſtamina, &c. or Male organs; but not the piſtillum ſtyle and ſtigma, the female organs. See STAMINA, PISTILLUM, and FEMINEUS *Flos*.

Male Flowers are produced either upon ſeparate plants from the females, as in all the plants of the claſs *Dioecia*, or on the ſame plant with the females, as in cucumber, melon, and all other plants of the claſs *Monoecia*, ſo that Male and female flowers, ſeparated on diſtinct plants, conſtitute the claſs *Dioecia*; and ſeparated on the ſame plant, the claſs *Monoecia*; thoſe of the latter are alſo androgynous, that is, a mixture of both Male and female flowers on the ſame plant. See ANDROGYNA *Planta*, and the claſſes *Dioecia* and *Monoecia*.

MATRICARIA, Feverfew.

The plants are hardy herbaceous perennials of upright growth, valuable in medicine, and to ornament the pleaſure garden, riſing two or three feet high, garniſhed with compound pinnated leaves, and terminated by many compound radiated flowers.

Claſs and order, *Syngeneſia Polygamia Superflua*.

*Characters.*] CALIX, a compound radiated flower, having a hemiſpherical general cup, compoſed of linear imbricated ſcales. COROLLA, the general flower is compound and radiated, having the diſc compoſed of numerous funnel-ſhaped hermaphrodite florets, five-parted and ſpreading at top, and oblong flat female florets compoſe the radius. STAMINA, in all the hermaphrodites five ſhort filaments and cylindric antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and in the hermaphrodites a bifid patent ſtigma, in the females two revolute ones. PERICARPIUM, none, many oblong naked ſeeds.

There are ſeveral ſpecies, but not more than one that have any particular merit, viz.

MATRICARIA *Parthenium*.

*Common Feverfew.*] Hath very fibrey cluſtering roots; crowned with numerous compound leaves; upright ſtalks branching on every ſide, two or three feet high; garniſhed with compound plane leaves, of ſeven oval folioles, cut into many parts; and all the branches terminated by many compound, radiated, white flowers, having a yellow diſc.

*Varieties.*] With full double flowers—with ſemi-double flowers—with double fiſtular flowers——with a fiſtular diſc and plane radius—with ſhort-rayed flowers—with rayleſs flowers——with rayleſs ſulphur-coloured heads—with finely curled leaves.

This ſpecies and all its varieties flower abundantly in June, each flower compoſed of numerous hermaphrodite and female florets, the former compoſe the diſc, the latter the radius, or border, and which, in the double and in the fiſtulous kinds, are very ornamental in gardens, but of diſagreeable odour, and are all ſucceeded by plenty of ſeed in autumn.

The plants are moſtly perennial in root, though in ſome moiſt ſoils are rather biennial or but of two or three years duration.

They

They have all a diſagreeable odour, but poſſeſs exceedingly great merit as medical plants, being very efficacious in many diſorders, and for which properties they are worthy of a place in every garden.

Conſidered alſo as plants of ornament, all the doubles and fiſtular flowered kinds, and the curled-leaved ſorts, are proper furniture for any of the compartments of the pleaſure-garden, where in aſſemblage they will effect a very agreeable variety, and the flowers will continue a month or ſix weeks in beauty.

*Propagation.*

The propagation is by ſeed, parting the roots, and by cuttings.

By Seed.—All the varieties are tolerably permanent from ſeed, where they ſtand ſeparate at a diſtance. Sow it in March and April, upon a bed or border of light earth, and rake it in; and when the plants are two or three inches high, plant them out in nurſery rows, ſix inches aſunder, to remain till autumn, then tranſplant them finally, and they will all flower the following ſummer.

By parting the Roots.—All the ſorts may be propagated in plenty by this method; but is effectual for continuing any approved variety of the double-flowered and curled-leaved kinds, or any other ſort; obſerving previous to this method of propagation, that in order to encourage the plants to afford ſlips, their flower-ſtalks, as ſoon as the flower begins to fade, ſhould be cut down cloſe, when the plants will more readily puſh out freſh heads, or offſets at bottom, both for continuing the roots, and for propagation; and they may be ſlipped or divided for encreaſe, either in autumn or ſpring.

By Cuttings.——This, like dividing the roots, is the certain method for continuing any particular variety. The cuttings of the young ſtalks planted in ſpring or ſummer, in a ſhady border, in the uſual way, will readily grow, and become good plants by autumn.

Remark: it is always proper to raiſe ſome of the beſt varieties every year or two from ſeed, as before directed, to ſupply the place of any old roots that may prove biennial.

MEDEOLA, Climbing African Aſparagus.

The plants are herbaceous, one of which is a climbing exotic of Africa, cultivated here as a green-houſe plant; is adorned with pinnated leaves, and hexapetalous, ſpreading, revolute flowers.

Claſs and order, *Hexandria Trigynia.*

*Characters.*] CALIX, none. COROLLA, ſix oblong-oval, ſpreading, revolute petals. STAMINA, ſix awl-ſhaped filaments, and incumbent antheræ. PISTILLUM, three corniculated germens, three ſtyles, and recurved ſtigmas. PERICARPIUM, a roundiſh, trifid, trilocular berry, and three heart-ſhaped ſeeds.

There are but two ſpecies, one of which a tall climber, the other a ſmall erect plant; but it is the climbing ſort that is uſually cultivated, of which there are two varieties, both for the green-houſe.

MEDEOLA *Aſparagoides.*

*Climbing African Aſparagus.*] Hath roots compoſed of ſeveral oblong, fleſhy knobs, united at top; ſending up annually long, climbing, very branchy ſtalks, winding round any ſupport four or five feet high; pinnated leaves, compoſed of oval, ſpear-ſhaped, alternate folioles; and from the ſides of the branches white flowers, ſingly, and by twos on each foot-ſtalk.

*Variety.*] Narrow-leaved; having weaker ſtalks, and longer and narrower leaves.

Both the varieties flower here in October and November, each flower of ſix ſpreading, rolled petals, and the ſeed ripen in ſpring.

They are perennial in root, and annual in ſtalk, which generally die to the ground every ſummer, and new ones ſhoot up in autumn, continue their growth all winter, and exhibit their leaves and flowers in full vigour.

They muſt be potted in light rich earth, and placed among the green-houſe plants to have ſhelter in winter; afford them moderate watering all the year, and larger pots occaſionally.

The propagation is by parting the roots; they furniſh off-ſets freely, and the proper time to take them off is in ſummer, when the ſtalks are decayed: plant each in a pot of good earth, and place them in the ſhade, and give occaſional light waterings; they ſhoot up ſtalks in the end of Auguſt, or early in September; place ſticks for them to twine upon, and in autumn move them into the green-houſe, where they will exhibit their foliage, and flower moſt part of winter.

MEDICAGO, *(Medica)* Medick.

This genus furniſhes a ſhrubby ever-green for the green-houſe and ſhrubbery, herbaceous

annuals for the pleaſure-garden, and that celebrated herbaceous perennial called Lucerne, for field culture, as fodder for cattle; all of them garniſhed with trifoliate leaves, and papilionaceous flowers.

Claſs and order, *Diadelphia Decandria*.

*Characters.*] CALIX, is monophyllous, bell-ſhaped, and divided into five acute ſegments. COROLLA, is papilionaceous, conſiſting of an oval, entire, reflexed ſtandard, two oblong-oval wings, and an oblong, bifid, obtuſe, reflexed carina, bending from the vexillum. STAMINA, ten diadelphous filaments, and ſmall antheræ. PISTILLUM, an oblong, incurved, compreſſed germen, ſhort ſtyle, and ſmall ſtigma. PERICARPIUM, a long, compreſſed, inflexed pod, incloſing ſeveral reniforme ſeeds.

There are many ſpecies, but not more than three which have merit for our collection, one ſhrubby ever-green, one herbaceous annual, and an herbaceous perennial.

*Shrubby Kind for the Green-houſe and Shrubbery.*

It is retained commonly as a green-houſe plant, but will alſo ſucceed in the full ground in a warm ſituation.

[1]MEDICAGO *Arborea.*

*Tree Medicago, or Shrubby Moon-trefoil.*] Hath a ſhrubby ſtalk, branching numerous and erectly ſix or eight feet high, having the younger branches covered with a hoary ſilvery down; cloſely garniſhed with trifoliate, ever-green leaves, each compoſed of three ſmall wedge-ſhaped lobes, hoary underneath; and from the ſides of the branches, long foot-ſtalks, terminated by cluſters of bright yellow flowers, ſucceeded by moon-ſhaped pods.

This is a beautiful ever-green and flowering ſhrub, and exhibits a plentiful bloom, from ſpring till autumn, and if ſheltered in winter, continue in flower moſt part of the year.

It being a native of Italy, it, with us, is conſequently a little tender, and requires ſhelter in winter, either of a green-houſe, or of a warm ſheltered ſituation in the full ground, for it will live in the open air in the ſhrubbery in moderate winters; but as being rather impatient of ſevere froſt, it is proper always to keep ſome alſo in pots to move to ſhelter among the green-houſe plants.

*Herbaceous Annual Sort for the Pleaſure-Garden.*

There are ſeveral annual ſorts, but not more than one proper as garden plants, which is comprehenſive of ſeveral varieties, known in gardens by the names of Snails, and Hedgehogs, &c. ſo called from the different odd ſhapes of their ſeed-pods.

[2]MEDICAGO *Polymorpha.*

*Polymorphous Medicago, or Snail and Hedgehog-trefoil.*] Hath trailing herbaceous ſtalks, branching diffuſely; garniſhed with trifoliate leaves, having indented ſtipulæ; and from the ſides of the branches papilionaceous yellow flowers; ſucceeded by ſnail-ſhaped pods, of many different forms in the varieties.

*Varieties.*] Common Snail Medicago, having large ſmooth pods, ſhaped and twiſted like a ſnail——Hedgehog Medicago, having large prickly ſnail-ſhaped pods, being armed with ſpines, pointing every way like a hedgehog—with turbinated pods—with globular pods—with orbicular pods—with long crooked pods—with double pods—with cluſtered pods——with twiſted pods——with jagged leaves.

All theſe plants are admitted into the pleaſure-ground principally for the ſingularity of their ſeed-pods; they are very hardy, and eaſily raiſed from ſeed in the common ground.

They all flower, and exhibit their ſingular ſeed-pods in June and July, ripening ſeeds in autumn.

*Herbaceous Perennial for Field Culture.*

[3]MEDICAGO *Sativa.*

*Cultivated Fodder-Medicago, or Lucerne.*] Hath a ſtrong fibrey, deeply-penetrating, perennial root; many upright, ſmooth, annual ſtalks, riſing two or three feet high; garniſhed with trifoliate, alternate leaves, having ſpear-ſhaped lobes; and from the axillas racemus foot-ſtalks of purple flowers; ſucceeded by contorted pods.

This ſpecies is in great eſtimation as an article of huſbandry for fodder, and is now cultivated in fields in great plenty in many places, is of ſuch quick growth, as often to afford four or five different cuttings every ſummer.

*Varieties of it are*] With yellow flowers—With ſaffron-coloured flowers—with violet-coloured flowers—with ſtriped flowers.

*Pro-*

*Propagation of three Species.*

First ſort.—The *Medicago Arborea* is propagated by ſeed and cuttings.

By Seed.—In March or April ſow it on a warm border in ſhallow drills, half an inch deep; or, to bring them forwarder, may ſow them in pots, and plunge them in a hot-bed juſt to bring up the plants an inch or two high, then harden them by degrees to the open air; in winter following, all of them raiſed in either method, require ſhelter from froſt; and in ſpring plant ſome ſingly in pots, in order to be managed as green houſe plants, and plant ſome alſo out in nurſery-rows, in the full ground in a dry warm ſituation, to take their chance the year round.

By Cuttings.—In March or April cut off ſome robuſt young ſhoots, form them into cuttings from ſix to eight or ten inches long, plant them in a bed of light rich earth, or, to forward them more, may plant ſome in pots and plunge them in a hot-bed; in either method, give occaſional waterings, and ſhade from the mid-day ſun; they will all be well rooted by the end of ſummer, and next ſpring they may be tranſplanted, ſome into ſeparate pots for ſhelter in winter; others in nurſery rows in the full ground.

Second Sort.—The *Polymorphous Medicago*, is propagated by ſeed, ſowed annually where the plants are to remain, in the latter end of March or in April. Sow them in patches towards the fronts of the borders, ſeveral ſeeds in each, but when the plants come up, and a little advanced in growth, thin them to one or two of the beſt in each patch, they will all flower, and exhibit their ſeed-pods in June and July.

Third Sort.—The cultivated *Medicago*, or Lucerne, is propagated by ſeed in open fields, ſowed commonly in drills, where the plants are to remain; and once raiſed, is of many years duration.

This plant is now greatly extolled as a moſt excellent and profitable ſummer's fodder for all ſorts of cattle; it comes up in great abundance, and is of ſuch quick growth, as often to afford four or five different mowings from May until September; is generally given to the cattle green, cutting it down when from about ten to fifteen inches high, while the ſtalks remain ſoft and tender; it is alſo ſometimes made into hay for winter uſe; though its chief uſes is to cut and eat green; for which purpoſe there is ſcarcely any plant in nature equal to it, as conſidering, in the firſt place, it preſents itſelf very early in ſpring, before any other green fodder can be had, and during ſummer affords ſeveral diſtinct mowings for all ſorts of cattle; therefore in conſideration of the goodneſs of the nature of the plant as fodder, and the great abundance it affords, it highly merits culture, and ſucceeds in almoſt any ſoil, and the ſame crops continue good for many years.

It proſpers beſt in light dry ſoils, and in which it is of longeſt duration; for in ſtrong, or very moiſt land, although it may flouriſh at firſt, yet it is often apt to go off in three or four years; whereas in ſuitable dry ground, the ſame crop will flouriſh for half a century, and often proſpers well in any dry barren ground, where hardly any other crop will ſucceed.

But to proceed to its propagation, which, as already obſerved, is by ſeed in the ſpring of the year.

The ground is to be prepared for the reception of the ſeed by proper ploughing or digging; but for large quantities in fields, ploughing is the eligible tillage, repeating it as the nature of the land ſhall require; together with repeated harrowings, to render the ſoil fine for the reception of the ſeed, which ſhould generally be ſowed in ſhallow drills, and the proper ſeaſon is March and April.

The ſeed is ſold by moſt of the nurſery and ſeedſmen from about eight pence to a ſhilling per pound, and from ſix or eight to ten or twelve pounds is ſufficient for an acre of land; that is, by drill-ſowing ſix or eight pounds will be enough; but by broad-caſt, it will require ten or twelve.

Drill-ſowing is the moſt commonly practiſed, and is the moſt commendable method of ſowing this ſeed; therefore draw ſhallow drills ſcarce an inch deep, and half a yard or two feet aſunder: ſow the ſeeds in the drills thinly with an even hand, and cover them in evenly with the earth, the depth of the drills; but this method of drill-ſowing is ſometimes performed with a drill-plough, furniſhed with a hopper, for ſowing the ſeed as the drills are formed, covering them in the above depth; ſome, however, ſow the ſeed by broad caſt, and harrow it in, as the moſt expeditious method; but by drilling, the plants ſtanding diſtant in rows, affords a much better opportunity of cleaning the crop from weeds by broad-hoeing.

In

In either method of ſowing, the plants will ſoon come up, and be ready for mowing in June or July.

Remark. However, the crop will require occaſional cleaning from weeds: if in rows it may be expeditiouſly performed by broad-hoeing, which ſhould be performed for the firſt time ſoon after the Lucerne comes up, and which muſt be repeated occaſionally, eſpecially after each mowing; but in broad-caſt ſown crops, the plants riſing promiſcuouſly, the hoeing cannot be ſo readily performed; it, however, muſt be done as well as poſſible, at the ſame time cutting up the weakeſt plants where too thick, leaving them all at proper diſtances for the broad-hoe to paſs between, for the plants ſpread exceedingly, provided they have room, and each ſend up numerous ſtalks.

In June or July the Lucern will be grown fifteen or eighteen inches high, or more, and begin to flower, when the firſt mowing may be performed; and the plants ſhooting up again ſtrongly, afford another cutting in autumn, which is all that ſhould be performed the firſt year.

The ſecond year, however, and every year afterwards, will afford three or four cuttings at leaſt; early in May the firſt crop will be ready for mowing; which may be performed when the plants are about a foot high, or a little more or leſs; and in a month or five weeks interval, another ſuch crop will be ready, and this ſucceeded by another, &c. but when deſigned to make it into hay, two or three crops may be ſufficient; or it may be fed off occaſionally with ſheep in ſpring, ſummer, and autumn; but which ſhould generally be taken off in winter, until about February or March.

MEDICINAL PLANTS. Plants that are uſed in medicine.

Vaſt numbers of plants poſſeſs Medicinal properties, and are uſed accordingly. A great many of which grow wild in this country, and great numbers are of foreign growth, and imported hither dried, from many different parts of the world; but many eminent medical plants are alſo cultivated here in our gardens, the principal ſorts of which are fully treated of as they occur in the courſe of this work under their reſpective genera.

A liſt, however, of the principal Medicinal Plants of our gardens and fields collected into one point of view in this place, may be convenient in aſſiſting the memory in ſelecting the proper ſorts for a collection, referring to their reſpective genera for their culture; we therefore exhibit in the following alphabetical arrangement, a liſt of the genera which furniſh the moſt material Medicnal Plants, pointing out thoſe ſpecies in each genera, by their reſpective ſpecific names, which are the moſt commonly uſed, conſiſting of herbaceous, perennials, biennials, and annuals, and of ſome trees and ſhrubs; remarking, that ſome of moſt of the ſorts are alſo valuable for other uſes beſides medicine; ſome for œconomical uſes, and ſome for variety and ornament in gardens; all of which are illuſtrated under their proper heads; obſerving alſo, that moſt of the ſorts in this liſt are hardy enough to grow here in the open ground, ſome of which grow wild in the fields, &c.

VIOLA, Violet.
——— *Odorata.*
——— *Tricolor.*
VITEX, Chaſte-tree.
——— *Agnus caſtus.*
VISCUM, Miſtoe.
——— *Alba.*

The abovelist of Medicinal Plants, by being collected from the different parts of the work under one head, will greatly aſſiſt the memory in making a collection of theſe kinds, or for procuring them for uſe; many of which however, poſſeſs a conſiderable ſhare of merit for other domeſtic uſes, as well as for variety and ornament in gardens, as before ſuggeſted; all of which, together with their general culture, is fully explained under their reſpective genera, as above, as they alphabetically arrange in the courſe of the work.

MELIA, *Azedarach)* Bead-tree.

This genus conſiſts of ſome deciduous and ever-green exotic trees of the Indies, proper for the ſhrubbery, green-houſe and ſtove; riſing near twenty feet high; adorned with large pinnated or winged leaves, and cluſters of pentapetalous flowers.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, is ſmall, monophyllous, and five-parted. COROLLA, five long, narrow, ſpear-ſhaped, ſpreading petals, a cylindric, monopetalous nectarium much indented at the brim. STAMINA, ten very ſmall filaments inſerted into the top of the nectarium, and ſmall oblong antheræ. PISTILLUM, a conical germen, cylindric ſtyle, and capitated quadrivalvular ſtigma. PERICARPIUM, a globular drupaceous fruit, containing a roundiſh, five-furrowed, quinquelocular nut, each cell having one ſeed.

There are but two ſpecies, one of which is a deciduous tree for the green-houſe and ſhrubbery, having an ever-green variety for the ſtove; and the other ſpecies is alſo of the temperature of ſtove-plants.

*Shrubbery and Green-houſe Kinds.*

1 MELIA *Azedarach.*

*Azedarach, or common Deciduous Bead-tree of Syria.*] Riſes with an upright robuſt ſtem, branching widely all around, about twenty feet high; large bipinnated, or double-winged deciduous leaves, of numerous folioles, each wing terminated by an odd one; and from the ſides of the branches long bunches of ſmall blue flowers; ſucceeded by roundiſh oblong, deeply five-furrowed, yellowiſh fruit, not eatable.

The fruit of this plant in Catholic countries is ſtrung like beads, to compoſe ſome ſort of roſaries; whence the name of Bead-tree.

This ſhrub is cultivated here ſometimes in the ſhrubbery, but more commonly as a green-houſe plant; for, being a native of hot countries, in theſe parts it is rather tender. Some ſhould be kept in pots to have ſhelter in ſevere weather,

weather, as a reſerve, in caſe thoſe in the ſhrubbery ſhould be deſtroyed.

It is very ornamental in its large, compound, doubly-winged foliage, which are often near two-feet long.

*Hot-houſe Kinds.*

*Variety.*] *(Melia Azedarach.)*

*Ever-green Semperflorous, Common Bead-tree of Ceylon*] Hath an upright ſtem, branching widely all around, about twenty feet high; large bipinnated ever-green leaves; and long paniculated bunches of blueiſh flowers, ſucceeded by roundiſh purple fruit; flowers always, or at leaſt moſt part of the year.

2 MELIA *Azadirachta.*

*Azadirachta, or Indian Bead-tree.*] Hath an upright robuſt ſtem, branching widely, and grows twenty feet high or more, covered with a dark-purple bark; pinnated or ſingly-winged leaves, of five or ſix pair of oblong lobes, terminated by an odd one; and from the branches long paniculated bunches of white flowers; ſucceeded by oval, olive-ſhaped, purple fruit, not eatable.

The flowers of all theſe ſhrubs are, ſeparately, ſmall, each of five ſpreading petals; but many being collected into long cluſters, they are tolerably conſpicuous.

All the three ſpecies merit culture in every garden accommodated with proper conveniences, they being very ornamental in their pinnated foliage.

The firſt ſort, however, will ſucceed tolerably in the open ground in a dry warm ſituation, though it is rather ſubject to be hurt by ſevere froſt: it is nevertheleſs proper to have ſome always in every curious ſhrubbery, to take their chance of all weathers, where, by the diſplay of their elegant bipinnated foliage, they will effect a very diſtinguiſhable variety: it is alſo proper to have ſome always in pots, and managed as green-houſe plants, both to encreaſe the variety, and be as a reſerve in caſe thoſe fully expoſed ſhould be killed in ſevere weather.

But the other two ſorts, the ever-green variety of the common Bead-tree, and the *Azadirachta*, being natives of very hot countries, require the almoſt conſtant aid of our ſtoves here.

The propagation of all the ſorts is by ſeed, aſſiſted by hot-beds.

Firſt Sort.—The ſeeds are obtained from abroad, and generally arrive in ſpring, which ſow in pots of light rich earth, and plunge them in a hot-bed of tanner's-bark or dung, under frame and glaſſes; in which they will come up in a month or ſix weeks, giving frequent waterings, and freſh air; and in June ſhould be fully expoſed in a moderate ſhade until October, then placed under a frame, &c. there to enjoy the free air all winter in open weather, and ſheltered from froſt; and in March following plant them in ſeparate ſmall pots, which plunge in a bark-bed, &c. tho' this is not abſolutely neceſſary, but if practiſed, it will greatly facilitate their rooting and firſt effort of growth; obſerving to indulge them freely with freſh air; and in June, as before obſerved, move them into it fully for the remainder of the ſummer, and allow them ſhelter again in winter, as above: which after being repeated three or four years, ſhifting them occaſionally into larger pots, ſome of the ſtrongeſt and moſt woody plants may be committed to the full ground under a warm wall, or in a dry ſheltered part of the ſhrubbery; and the proper ſeaſon for this work is the firſt fortnight in April; reſerve a quantity alſo in pots to have the management of green-houſe exotics, leſt thoſe in the open ground ſhould be cut off by the froſt.

Second and Third Sorts.—Both theſe ſorts are alſo propagated by ſeeds, ſowed in pots and plunged in the bark-bed, and managed nearly as the firſt ſort, only as being of much more tender quality, muſt be kept always in pots, and plunged in the tan-bed in the ſtove during their infant ſtate; afterwards, having acquired ſome conſiderable ſize and ſtrength, they may be placed in the open air for about two months in the heat of ſummer, and the reſt of the year in the hot-houſe; manage them as other woody exotics of that department. See STOVE PLANTS.

MELIANTHUS, Honey-flower.

Two tall, ligneous, floriferous, perennial exotics for the green-houſe and ſhrubbery, conſtitute this genus, riſing with durable ligneous ſtalks, four or five feet high or more; ornamented with large winged leaves; and terminated by long ſpikes of tetrapetalous flowers.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX, is large, unequal, five-parted, and coloured. COROLLA, four ſpear-ſhaped, narrow, ſpreading, reflexed-pointed petals, and a monophyllous, ſhort, compreſſed, indented nectarium, ſituated in

the lower ſegment of the calix. STAMINA, two long and two ſhort filaments, and oblong, heart-ſhaped antheræ. PISTILLUM, a four-cornered germen, erect ſtyle, and quadrifid ſtigma. PERICARPIUM, a quadrangular, ſemi-quadrifid capſule, having acute diſtinct angles, and divided by partitions into diſtended cells, each having one globular ſeed.

There are but two ſpecies, both natives of Africa, and being rather of a tender nature, are very commonly treated as green-houſe plants; but they will alſo often ſucceed all the year in the open-ground, in warm dry ſituations; it is, however, proper to cultivate ſome by both methods.

The ſpecies are;

[1]MELIANTHUS *Major.*

*Major Melianthus, or Honey-flower.*] Hath a thick, ligneous, ſpreading root; many upright, ligneous, durable ſtalks, riſing ſix or eight feet high; garniſhed with large pinnated leaves, of four or five pair of ſerrated lobes, terminated by an odd one, and have ſingle ſtipulæ growing cloſe to the foot-ſtalks; and from the ſides and top of the ſtalks long ſpikes of chocolate-coloured flowers.

[2]MELIANTHUS *Minor.*

*Minor Melianthus.*] Hath a thick, ligneous, ſomewhat, ſpreading root; upright, ligneous, ſoft, durable ſtalks, riſing four or five feet high, garniſhed with ſmaller pinnated leaves, of four or five pair of folioles, terminated by an odd one, and have two diſtinct ſtipulæ; and from the ſides and ends of the branches long, looſe, pendulous bunches of flowers tinged with green, ſaffron-colour, and red.

Both the ſpecies flower about June; each flower is of four ſpear-ſhaped ſpreading petals; and each plant produces many flowers annually, but rarely are ſucceeded by ſeeds in England.

The plants are very ornamental, both in foliage and flowers, and merit admittance in every collection.

They are durable both in root and ſtalk, for although the ſtems are ſomewhat of an herbaceous nature, they become woody and abiding, more eſpecially if ſheltered occaſionally in winter; but thoſe fully expoſed are ſometimes killed down to the ground in ſevere weather, but the roots generally remaining ſound, ſend up new ſtalks again in the following ſpring.

Conſidered as green-houſe plants, it is proper to keep ſome always in pots to have ſhelter in winter, in caſe thoſe in the open ground ſhould be deſtroyed.

And for the pleaſure-garden, plant ſome in a dry ſoil, in a ſheltered warm expoſure.

Their propagation is eaſily effected by ſuckers, and cuttings.

By Suckers.—Theſe riſe in tolerable plenty from the root, eſpecially of the firſt ſort; and may be taken up in autumn or ſpring, with fibres, and planted ſome in pots for the green-houſe, others in a warm dry part of the nurſery, &c.

By Cuttings.—In ſpring or ſummer take off a quantity of young cuttings towards the tops of the ſtalks or branches, plant them in pots, and plunge them in a hot-bed, giving waterings, they will readily put out roots: or in default of a hot-bed, cover them cloſe with hand-glaſſes, giving occaſional ſhade, they will alſo take root; managing them afterwards as directed for the ſuckers.

MELISSA, Baum, or Balm.

It furniſhes hardy, fibrous-rooted, herbaceous perennials, for medical uſes, and variety in gardens, riſing with upright ſlender ſtalks, from one to two or three feet high, garniſhed with ſimple, oblong, oppoſite leaves, and verticillate cluſters of ſmall monopetalous ringent flowers.

Claſs and Order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, is monophyllous, bell-ſhaped, angular, bilabiated at top, and permanent. COROLLA, is monopetalous, with a cylindric tube, and ringent above; having the upper lip ſhort, round, erect, arched, and indented in two, the lower one trifid, with the middle part largeſt. STAMINA, two longer and two ſhorter filaments, and ſmall antheræ that join by pairs. PISTILLUM, a quadrifid germen, ſlender ſtyle, the length of the corolla, ſituated with the ſtamina, under the upper-lip, and a bifid reflexed ſtigma. PERICARPIUM, none; four naked ſeeds lodged in the permanent calix.

There are ſeveral ſpecies, but the following perennials are the only ſorts for general notice.

[1]MELISSA *Officinalis.*

*Common Officinal Baum.*] Hath fibrey perennial roots; many upright, ſquare, branchy, annual ſtalks, riſing two or three feet high; garniſhed

garniſhed with oblong, indented, oppoſite leaves, by pairs, two or three inches long, and half as broad; and from the upper axillas verticillate cluſters of ſmall white flowers, upon ſingle foot-ſtalks.

*Variety.*] With variegated leaves.

The common Baum is a valuable medical plant, the virtues of which are univerſally known, and ought to be allowed a place in every garden, and may be encreaſed in great plenty by parting the roots.

The variegated kind exhibits an agreeable variety in the pleaſure garden.

[2]MELISSA *Grandiflora.*

*Grandiflorous Meliſſa, or Hetrurian Calamint.*] Hath fibrey perennial roots; upright annual ſtalks, riſing about a foot high; garniſhed with oblong-oval, indented, hairy, oppoſite leaves; and from the upper axillas verticillate cluſters of large purple flowers, on forked foot-ſtalks.

[3]MELISSA *Calamintha.*

*Common Calamint of the Shops.*] Hath fibrey perennial roots; upright, ſquare, branchy, hairy ſtalks, riſing a foot high; roundiſh, indented, oppoſite leaves; and verticillate cluſters of ſmall blueiſh flowers, on forked foot-ſtalks as long as the flowers.

All theſe three ſpecies of *Meliſſa* flower in June and July; each flower is of one ringent, labiated petal, and are diſpoſed in a verticillus, or whorls, in ſmall heads, or cluſters, going quite round the ſtem, on ſhort foot-ſtalks (ſee VERTICILLUS); and are ſucceeded by ripe ſeeds in autumn, but theſe are hardly ever wanted, ſince all the ſorts multiply greatly by root.

They are all perennial in root, but annual in ſtalk, and all ſo hardy as that they will grow in almoſt any ſoil and ſituation.

The plants are fragrant, warm, and accounted cordial and cephalic; their chief virtue reſides in the leaves.

As to their merit in gardens, they are proper both for uſe and ornament.

The *Meliſſa Officinalis*, or common Baum, merits a place in every garden for its admirable medical qualities, as well as for ſome culinary uſes; is eaſily propagated by ſlipping the roots, and ſhould be diſpoſed in the kitchen-garden among the aromatics, in rows about a foot aſunder (ſee the *Propagation*); and its variegated ſort may be diſpoſed in the pleaſure-ground. So refreſhing is the ſmell of both the varieties, ſo ſalutary and cooling when made into tea, by way of medicine, that they have the firſt claim to a place in our gardens. Great quantities of the common green ſort are cultivated in the gardens about London for ſupplying the markets, and is of ſuch quick growth, that it often affords three or four cuttings each ſummer, to cut young for immediate uſe; though when wanted for principal medical purpoſes, or to dry for keeping, it ſhould generally ſtand till arrived nearly at full growth, and juſt beginning to flower, then cut it in dry weather, and dry it in the ſhade, as directed for the mint. When any is deſigned for market, either young or at full growth, tye it in bunches, a good handful in each; which in Londen ſell at from ſix pence to a ſhilling per dozen of bunches.

The ſecond ſort is commonly introduced into pleaſure-gardens, as a plant of ornament and variety.

But the third ſort is chiefly conſidered as a medical plant, though inferior to the common Baum, and as it grows wild in England, is rarely cultivated, except in phyſic gardens.

*Propagation of all the Sorts.*

The propagation of all the ſorts is effected plentifully by parting the roots, which encreaſe exceedingly by off-ſets annually.

Autumn or ſpring is the proper ſeaſon for this work, though it may be done any time in open weather, from the decay of the ſtalk in autumn until ſpring, before new ones begin to ariſe; the moſt eligible ſeaſon, however, is September or October, that the off-ſets may take good root before winter, and be firmly eſtabliſhed againſt ſpring; particularly the common Baum.

The method is, the whole root may either be taken up and divided into as many ſlips as are furniſhed with fibres; or the main root may ſtand, and ſlip off a quantity of off-ſets around the out-ſide; plant thoſe of the common ſort, &c. for uſe, in the kitchen-garden, in four-feet wide beds, in rows of a foot or eighteen inches aſunder, and a foot diſtance in each row; they will ſpread and encreaſe into large bunches the following ſummer, and afford a good cutting or two the ſame year; thoſe intended for ornament or variety, ſuch as the variegated common Baum, and the and the Grandiflorous *Meliſſa*, ſhould be diſperſed ſingly in the different compartments where they are wanted.

All the culture theſe plants require is keeping them clean from weeds: and cut down all remaining ſtalks in autumn; at which time alſo clear off all weeds from the beds of com-

mon

mon Baum, and dig the alleys and ſpread a little of the earth over the ſurface of the beds between the plants, whereby the beds will remain neat all winter, and it will prove beneficial to the plants.

A plantation of Baum will remain in good condition ſeveral years; though if renewed every third or fourth year, is the way to continue a ſucceſſion of crops in full perfection.

MENTHA, Mint, Penny-Royal, &c.

The plants are hardy, herbaceous, aromatic perennials for the kitchen-garden, of admirable ſalutiferous properties, both for culinary purpoſes and medicine; have all creeping perennial roots, ſending up ſtalks annually; ſome erect and two or three feet high, others trailing and ſcarce a foot long; all the ſorts are garniſhed with ſimple, oblong, and oval leaves, and terminated by verticillate ſpikes, and cluſters of numerous, ſmall, monopetalous, tubulous flowers.

Claſs and order, *Didynamia Gymnoſpermia*.

*Characters.*] CALIX, is monophyllous, tubular, erect, five-parted, and permanent. COROLLA, is monopetalous, tubular, erect, and divided into four parts, the upper largeſt and emarginated. STAMINA, four didynamious filaments, and roundiſh antheræ. PISTILLUM, a quadrifid germen, ſlender ſtyle, and ſpreading bifid ſtigma.. PERICARPIUM, none; four ſeeds lodged in the calix.

To this genus is now joined the *Pulegium*, or Penny-Royal.

There are many ſpecies of *Mentha*, moſt of which grow wild in this country by the ſides of brooks, rivers, and watery ditches; but of which there are ſeldom more than three ſpecies cultivated, viz.—common green Spear-Mint—Pepper-Mint—and *Pulegium*, or Penny-Royal.

The moſt material ſpecies are;

[1]MENTHA *Viridis*.

*Green Mint, or common Spear-Mint.*] Hath long creeping very ſpreading roots; upright, ſquare, ſingle, green ſtalks, riſing two or three feet high; garniſhed with oblong, ſerrated, cloſe-ſitting, ſmooth, very green leaves; and the ſtalks terminated by purpliſh flowers, in oblong erect ſpikes; the ſtamina longer than the corolla.

*Varieties.*] Broad-leaved—narrow-leaved—curled-leaved—variegated-leaved.

This is the ſpecies of *Mentha* the moſt commonly eſteemed and cultivated in kitchen-gardens for all culinary uſes, as for ſauces, ſallads, &c. and for ſeveral medical purpoſes: and the curled leaved and variegated ſorts of it, are employed in the pleaſure-garden for variety. It grows wild in England, but has been long cultivated in gardens, and is ſuperior in quality to the two immediately ſucceeding ſpecies, which are alſo of the Spear-Mint kind.

The appellation Spear-Mint is derived from ſpear-like form of the ſpikes of flowers.

[2]MENTHA *Sylveſtris*.

*Wild, long, hoary-leaved Spear-Mint.*] Hath long, thick, ſpreading root; upright, ſquare ſtalks, two feet and a half high; oblong, ſerrated, hoary, cloſe-ſitting leaves; and the ſtalks terminated by pale-red flowers in oblong erect ſpikes, the ſtamina longer than the corolla.

[3]MENTHA *Rotundifolia*.

*Round-leaved Spear-Mint.*] Hath long ſpreading roots; upright ſtalks, two feet high; large, roundiſh, rough, crenated, cloſe-ſitting leaves; and the ſtalk terminated by flowers in oblong erect ſpikes.

Theſe laſt two ſpecies, *Mentha Sylveſtris* and *Rotundifolia*, grow wild here in moiſt places, are often diſtinguiſhed by the names of Horſe Mint; and are ſometimes cultivated, though are ſuppoſed inferior to the firſt ſpecies, *Mentha Viridis*, which is very diſtinguiſhable from both theſe ſpecies; as alſo from the following:

[4]MENTHA *Piperita*.

*Pepper-Mint.*] Hath long, thick, creeping roots; upright, branchy, purple ſtalks, two feet and a half high; garniſhed with oval-oblong, ſerrated, dark-green leaves, having foot-ſtalks; and the ſtalks and branches terminated by purple flowers in roundiſh heads, the ſtamina ſhorter than the corolla.

This ſpecies is of a hot biting taſte; is in univerſal eſtimation as a medicinal herb, greatly uſed for diſtilling, and of which is prepared that fine ſalutary cordial, called Pepper-Mint Water.

The following varieties of *Mentha* are of different ſpecies, and cultivated principally for variety—Orange Mint, having roundiſh leaves, ſmelling like orange-peel—gold ſtriped orange Mint—yellowiſh orange Mint—reddiſh orange Mint—hoary white Mint—ſilvery ſpotted Mint—hoary variegated white and green Mint——variegated white and green, tinged with red. Moſt of theſe varieties are

ſtrongly ſcented, ſome like an orange, others reſembling baum, and ſome like penny-royal.

*Penny-Royal Kinds.*

5MENTHA *Pulegium.*

*Pulegium, or Penny-Royal.*] Hath ſmall, fibrey, very ſpreading roots; ſmall, trailing, roundiſh, rooting ſtalks, ſpreading every way, taking root as they advance; garniſhed with ſmall, oval, obtuſe, crenated leaves; and the ſtalks terminated by verticilli of purple flowers, having the ſtamina longer than the corolla.

This ſpecies is a fine aromatic; it grows wild upon commons, &c. in many parts of Britain; and is cultivated in kitchen-gardens as a culinary herb.

6MENTHA *Cervina.*

*Cervine Upright Penny-Royal.*] Riſes with erect ſtalks, branching on every ſide, a foot and a half high; garniſhed with linear or very narrow thickiſh leaves; and terminated by verticilli of purple flowers.

All theſe ſix ſpecies of *Mentha*, and reſpective varieties, are perennial in root, but the ſtalks riſe in ſpring and decay in autumn.

They flower in June and July: the flowers are moſtly very ſmall, each of one tubular petal, of no beauty, and are ſucceeded by ripe ſeeds in autumn; but the ſeeds are rarely uſed, the plants being all generally propagated either by parting the roots, by young off-ſet plants, or by cuttings.

The plants are all exceedingly hardy, and proſper in any common ſoil of a garden.

They are all of a warm, fragrant, aromatic, and cordial nature, and their virtues reſide in their ſtalks and leaves, and moſt of the Mint kinds poſſeſs excellent medical properties.

With reſpect to their particular merit as garden plants; the common green Spear-Mint is valuable both as a culinary and medical herb; but the Pepper-Mint principally for medical uſes, and for which it is greatly eſteemed, and is generally diſtilled: and the Penny Royals are proper both for kitchen uſes and medicine. Obſerving, that for all of which purpoſes they merit culture in every kitchen-garden, where they ſhould be diſpoſed chiefly in four-feet wide beds, having foot-and-a-half alleys between, the plants, placed in rows lengthways in the beds, ſix or ſeven rows in each, as directed in their propagation.

For kitchen uſes the common green Mint and Penny-Royal are the moſt proper whilſt young and tender, as in ſpring and beginning of ſummer; but by cutting down ſome of their ſtalks occaſionally in ſummer and autumn, a ſucceſſion of young ſhoots may be continued from Mint until October or November; and by the aid of hot-beds, young Mint may be obtained all winter until the common crop comes up in ſpring, as directed in their propagation.

But when any of the ſorts of *Mentha* are required for drying to keep, or are wanted for diſtilling or other medical uſes, they ſhould be permitted to grow up to their full height, till juſt beginning to flower; they are then in the greateſt perfection for thoſe purpoſes.

When any of theſe plants are intended to be dried for keeping for winter uſe, cut them in dry weather, and ſpread them in a dry airy place to dry, but not in the ſun, which would dry them too faſt, and exhauſt their goodneſs; therefore mark this, and ſpread them, or hang them up in bunches, where they may be out of the wet and ſun, and dry gradually.

*Propagation of the Mint Kinds.*

Previous to the work of propagation we will in the firſt place juſt hint, that for the reception of all the ſorts for uſe, prepare, in the kitchen garden, four-feet wide beds, having foot-and-half alleys between, for the convenience of going in to clean, water, and cut the crops, as alſo for earthing the beds a little in autumn, by way of dreſſing, both for neatneſs and to encourage the plants.

But to the propagation: all the ſorts of Mint are propagated either by parting the roots, by young off-ſet plants, or by cuttings.

By Parting the Roots.—In autumn or early in ſpring, before the young ſhoots begin to appear, dig up from any old plantation a quantity of roots, and divide them into ſmaller parts, and of which chuſe the ſtrongeſt and freſheſt for planting; then proceed to plant them in drills, which draw with an hoe lengthways the bed, an inch and a half deep, and half a foot aſunder, ſeven in each bed; and along the bottom of each drill place the roots of the mint thinly, covering them over with the earth, to the depth of the drills, then lightly rake the ſurface ſmooth, and the work is done.

They will readily grow, and afford plenty of young Mint the enſuing ſpring and ſum-

mer for ſallads, and culinary uſes; alſo, if ſuffered to run up, will afford one or two good cuttings at full growth for drying, or for diſtilling.

By Young Plants.——In beds of Mint of ſome ſtanding, young ſhoots riſe numerouſly in ſpring, ſo as to admit of thinning; and a quantity of the moſt robuſt of which, drawn out with fibres at their bottom, form fine ſets or plants for making a new plantation; therefore in April or May, when the ſhoots are advanced five or ſix inches long, take the opportunity of ſhowery weather, and proceed to take up a quantity of the ſtrongeſt, having a knife to aſſiſt in raiſing and ſeparating them from the old roots, they will readily riſe with roots to each; then proceed with line and dibble to plant them in rows, ſix inches apart, and four inches aſunder in the rows, ſeven rows in each bed, each plant half way into the ground, and finiſh with a good watering, repeating it occaſionally; and they will very ſoon take root, ſpread at bottom, and afford a full crop the ſame year.

By Cuttings.—In May or June, in moiſt weather, cut off a quantity of the ſtrongeſt ſhoots or ſtalks near the bottom, and divide them into cuttings ſix inches long: plant them by dibble in rows, ſix inches aſunder, in beds as above, give water directly, and repeat it in dry weather; they will ſoon take root, ſpread at bottom and produce a full crop the ſame ſummer.

The above three methods of propagation holds good with all the ſorts of Mint.

Obſerve, however, thoſe deſigned to form variety in the pleaſure-garden ſhould be diſpoſed in patches in different parts.

A plantation of Mint for uſe, will afford ſeveral cuttings every ſummer, when it is only required young for preſent uſe, for culinary purpoſes; but when required for drying to keep till winter, or wanted green for medical uſe, they ſhould generally be ſuffered to ſtand until July, till nearly full grown, and juſt coming into flower; which being then cut down cloſe, the roots will ſend up another crop fit to cut again towards Michaelmas: each cutting, whether to be cut young, or when at full growth, ſhould always be cut as cloſe to the ground as poſſible.

When any is deſigned for market, bind them in bunches, a large handful in each, they ſell at about nine pence or a ſhilling per dozen.

The general culture of all the ſorts, is clearing them from weeds in ſpring and ſummer, cutting down all remaining ſtalks every autumn; clearing off alſo any autumnal weeds; and in October or November dig the alleys, and ſpread a little of the earth over the beds; this will give an air of culture and neatneſs, and prove beneficial to the crop.

A plantation of Mint, &c. will be of many years duration, but to have a conſtant ſucceſſion of good full crops, a freſh plantation ſhould be made every four or five years.

*Forcing Mint for Winter Uſe.*

Young green Mint is often required in winter for ſallads, ſauces, &c. but this can only be obtained by aid of hot-beds, and the common green Mint is the propereſt ſort; therefore, any time in winter from November until the beginning of February, a hot-bed may be made for this purpoſe. Make it but moderate, about two feet thick of dung will be ſufficient, and covered with garden-frames and glaſſes, or in default thereof, may be arched over and covered with mats; as ſoon as it is made and framed, earth it over with rich mould, ſix inches thick, then take up a quantity of roots out of the natural-ground bed, and ſpread them cloſe together upon the ſurface of the earth of the hot-bed, and mould them over cloſely an inch deep with fine earth, and put on the lights, or if mat-coverings are uſed, cover only on nights, and bad weather; but frames and glaſſes are the moſt eligible for the middle of winter; obſerving to tilt the lights to let off the ſteam, and to admit freſh air: the plants will ſoon come up plentifully, when continue to admit freſh air in fine weather, and give moderate waterings, and they will ſoon be ready for uſe.

When the plants thus raiſed are an inch or two high, or a little leſs or more, they may be cropped for uſe; they will readily break out again, and freſh ſhoots riſe from the bottom; ſo that the ſame bed will furniſh a ſupply of plants a long time; and two beds made at different times, may be ſufficient for the whole winter.

By the above practice of forcing Mint, you may obtain it young and green from the time the natural ground Mint goes off in autumn, until it comes in again in ſpring.

When it is, however, intended to force Mint every winter, a freſh plantation ſhould be made annually in the open ground for that purpoſe, to furniſh a ſufficiency of roots fit to take up at forcing time, without diſturbing thoſe of the principal crop.

*Penny-*

*Penny-Royal Kinds.*

Both the Penny-Royal ſpecies delight in a moſt ſoil; they, however, will both proſper in any good earth of the kitchen-garden.

They are propagated in great plenty either by ſlipping their roots, in autumn or ſpring, or by cuttings of their rooting-ſtalks, which ſpreading upon the ground emit roots from every part; and ſhoots of them may be taken off plentifully in ſpring, each well furniſhed with roots; the ſlips or cuttings in either way, are to be planted by dibble, in rows a foot aſunder; they will quickly ſet to growing, and ſpread about each way, and furniſh a full crop for uſe in ſpring and ſummer.

Their culture is nearly the ſame as the Mint, and a plantation will be of ſeveral years duration.

MENISPERMUM, Moonſeed.

It furniſhes ſome hardy climbers of America, for the ſhrubbery, riſing with climbing, ligneous, durable ſtalks, twining round any ſupport twelve or fifteen feet high, garniſhed with roundiſh peltate leaves, and bunches of polypetalous dioecious flowers.

Claſs and order, *Dioecia Dodecandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, having a perianthium of two ſhort narrow leaves. COROLLA, four exterior oval petals, and eight oval concave interior ones. STAMINA, twelve or more filaments in the males, and ſhort quadrilobed antheræ, and in the females eight filaments, having the antheræ barren. PISTILLUM, two ſmall, oval, incurved germina, ſolitary recurved ſtyles, and bifid ſtigma. PERICARPIUM, two roundiſh, reniforme, unilocular berries, having one large reniforme ſeed.

The chief ſpecies are;

[1]MENISPERMIUM *Canadenſe.*

*Canada Round-leaved Moonſeed*] Riſes with ſeveral climbing ligneous ſtalks, twining upon ſupport twelve or fifteen feet high; large peltated, cordate, roundiſh, angular leaves, on long twining footſtalks; and from the axillas looſe bunches of greeniſh flowers.

[2]MENISPERMUM *Virginicum.*

*Virginian Lobated-leaved Moonſeed.*] Riſes with climbing ligneous ſtalks, twining round ſupport twelve or fifteen feet high; large peltated, cordate, lobated leaves; and looſe bunches of greeniſh flowers.

Both theſe climbers flower here in July, each ſeparate flower is of about twelve oval petals, four exterior, and eight interior ones; and are ſucceeded by ripe ſeeds in autumn.

Theſe plants are employed as climbers in the ſhrubbery to form a variety, placed to twine round the ſtems of trees, or any other ſupport, or their numerous ſtalks and branches will twine and interweave one among another, and aſſume a buſhy growth: it is, however, proper to allow them ſome ſupport, for in America, their native ſoil, they climb up trees to a conſiderable height; ſo that here they are proper furniture for wilderneſs quarters to climb among trees and buſhes.

Their propagation is either by layers in autumn, which will be well rooted in one year; or, as they ſpread exceedingly in root, ſending up many ſhoots, which being ſeparated in autumn, each with roots to it, they will form proper plants.

They may alſo be raiſed from ſeeds, ſowed in ſpring in the open ground, half an inch deep; they will riſe the ſame year, managing them as other hardy ſeedlings.

MESEMBRYANTHEMUM, (*Ficoides*) Fig-Marigold.

This genus compriſes a numerous tribe of ſucculent, curious, floriferous exotics, of Africa, for the green-houſe collection, &c. conſiſting of one or two annuals, and many perennials; all of them with very ſucculent ſtalks and branches, ſome trailing and herbaceous, others erect and ſhrubby, and ſome acaulis; garniſhed with thick ſucculent leaves, of various ſingular forms in different ſpecies; and monopetalous multipartite flowers.

Claſs and order, *Icoſandria Pentagynia.*

*Characters.*] CALIX, is monophyllous, acutely five-parted and permanent. COROLLA, is monopetalous, and deeply divided into many narrow ſpear-ſhaped ſegments in ſeveral ſeries. STAMINA, twenty or more filaments, and capillary antheræ. PISTILLUM, an obtuſe five-cornered germen under the corolla; and moſtly five, but ſometimes ten or more ſtyles, with ſimple ſtigmas. PERICARPIUM, a roundiſh fleſhy capſule, having as many cells as there are ſtyles, with numerous roundiſh ſeeds.

There are between forty and fifty different ſpecies; all African plants from the Cape of Good-hope; near forty of which are retained in our gardens for variety, one of which is annual (Ice Plant); all the reſt are perennial for the green-houſe collection; and all the ſorts are of the ſucculent tribe, both in ſtalk and leaves, ſome with trailing ſtems, ſome

with ſhrubby firm ſtems, others looſe and pendulous, and ſome acaulis; and their leaves being moſtly thick and fleſhy, are of many different ſhapes, &c. in different ſpecies; ſome long and round like a cylinder, others three-ſquare, ſome taper, ſome tongue-ſhaped, ſcymetar-ſhaped, &c. ſome oppoſite and connate, or connected at the baſe, and ſome diſtinct; many are papuloſe, or pimply, others punctated, or dotted; ſome impunctated, or intirely ſpotleſs, or ſmooth, &c. all as in their following deſcriptions.

*Annual Sort.*

[1]MESSEMBRYANTHEMUM *Cryſtallinum.*

*Cryſtalline Meſembryanthemum, commonly called Diamond Ficoides, or Ice-Plant.*] Riſes with a ſhort, thick, ſucculent ſtalk, dividing low into many trailing, very ſpreading, ſucculent branches, beſpangled all over with icey pimples, very pellucid and glittering; oval, undulate, alternate, papuloſe or pimply, glittering leaves; and from the ſides of the branches numerous, almoſt cloſe-ſitting, white flowers, tinged with red or crimſon; ſucceeded by plenty of ſeed in autumn.

This ſingular and curious plant being cloſely covered with large pellucid pimples, full of moiſture, ſhining brilliantly like diamonds or bubbles of ice; whence it derives the name, as above; it is in great eſteem by the curious for its ſingularity, and highly merits a place amongſt the tender annuals of the pleaſure-garden.

*Perennial Sorts, all for the Green-Houſe.*

[2]MESEMBRYANTHEMUM *Geniculiflorum.*

*Jointed flowered Meſembryanthemum.*] Hath a ſhrubby ſucculent ſtalk; half-taper, papuloſe or pimply, diſtinct leaves; and white flowers, ſitting cloſe to the axillas, having quadrifid cups.

[3]MESEMBRYANTHEMUM *Noctiflorum.*

*Noctiflorous, or Night-flowering Meſembryanthemum.*] Hath a thick, ſhrubby, ſucculent ſtalk; half-cylindric, ſmooth, diſtinct leaves; and purple and white flowers on foot-ſtalks, having quadrifid cups; the flowers opening on nights.

[4]MESEMBRYANTHEMUM *Splendens.*

*Splendent, or Shining Meſembryanthemum*] Hath a ſhrubby, firm, ſucculent ſtalk and branches; ſemi taper, recurved, unſpotted, ſmooth, ſhining leaves, growing diſtinct in cluſters; and whitiſh flowers, having the cups terminating in digitate points.

[5]MESEMBRYANTHEMUM *Umbellatum.*

*Umbellated Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent ſtalk; awl-ſhaped, rough-ſpotted leaves, connate at the baſe, but ſpreading at top; and white flowers in a corymbus reſembling an umbel.

[6]MESEMBRYANTHEMUM *Calamiforme.*

*Calamiforme, or Quill-leaved Meſembryanthemum.*] Is acaulis, or without ſtalk; almoſt taper, impunctated or ſpotleſs, aſcending leaves, connate at the baſe; and octagynous, or eight-ſtyled, white flowers.

[7]MESEMBRYANTHEMUM *Bellidiflorum.*

*Daiſy-flowered Meſembryanthemum*] Is acaulis, or without ſtalk; narrow, three-cornered, ſpotleſs leaves, having the top indented into three parts; and ſmall purpliſh flowers.

[8]MESEMBRYANTHEMUM *Deltoides.*

*Deltoide-leaved Meſembryanthemum.*] Hath a ſhrubby, ſucculent ſtalk; deltoide-ſhaped, triangular, ſhort, thick, indented, ſpotleſs, diſtinct leaves; and pale-purple, fragrant flowers, ſingly.

[9]MESEMBRYANTHEMUM *Barbatum.*

*Bearded Star-pointed Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent ſtalk and branches; ſub-oval, papuloſe, or pimply leaves, diſtinct, bearded at the point in a radiated manner; and purple flowers.

[10]MESEMBRYANTHEMUM *Hiſpidum.*

*Hiſpid, or Briſtly Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent, hiſpid, downy ſtalk; cylindrical, papuloſe, diſtinct leaves; and pale-purple flowers.

*Varieties.*] With violet-coloured flowers——with orange coloured flowers——red flowers.

[11]MESEMBRYANTHEMUM *Villoſum.*

*Villoſe, or Hairy Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent, hairy ſtalk; narrow, ſemi-taper, channelled, downy, ſpotleſs leaves, connate at the baſe.

[12]MESEMBRYANTHEMUM *Scabrum.*

*Rough-leaved Meſembryanthemum.*] Hath a ſhrubby, ſucculent ſtalk; awl-ſhaped, diſtinct leaves, having all the under-ſide very rough and prickly; and violet-coloured flowers, with chaffy cups.

[13]MESEMBRYANTHEMUM *Emarginatum.*

*Emarginated Meſembryanthemum.*] Hath a ſhrubby, ſucculent ſtalk; awl-ſhaped, roughiſh leaves, in cluſters; and purple flowers, having the petals emarginated, and with ſpinous cups.

[14]MES-

[14]MESEMBRYANTHEMUM *Uncinatum.*

*Uncinated Meſembryanthemum, or Buck's-horn Ficoides* ] Hath a ſhrubby, jointed, ſucculent ſtalk; having the joints terminated by triangular, acute-pointed, connate leaves, indented underneath; and purple flowers.

[15]MESEMBRYANTHEMUM *Spinoſum.*

*Spinous, or Prickly Meſembryanthemum.*] Hath a ſhrubby, ſucculent ſtalk and branches, armed with branching ſpines; taper, three-ſquare, punctated, diſtinct leaves; and reddiſh-purple flowers.

[16]MESEMBRYANTHEMUM *Tuberoſum.*

*Tuberous rooted Meſembryanthemum.*] Hath a headed, tuberous root; ſhrubby, firm, ſucculent ſtalks; awl-ſhaped, bliſtered or pimply, diſtinct leaves, patulent or ſpreading at top; and purple flowers.

[17]MESEMBRYANTHEMUM *Stipulaceum.*

*Stipulaceous Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent ſtem; ſub-triquetrous, compreſſed, punctated, diſtinct leaves, in cluſters, having the baſe bordered; and purple flowers, nearly in a corymbus.

[18]MESEMBRYANTHEMUM *Craſſifolium.*

*Craſſifoliate, or thick-leaved Meſembryanthemum.*] Hath a nearly cylindrical, looſe, creeping ſtem; ſemi-cylindrical, thick, ſmooth, connated leaves, triquetrous at the top; and purple flowers.

[19]MESEMBRYANTHEMUM *Falcatum.*

*Falcated-leaved Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent ſtem; ſub-ſcymitar ſhaped, incurved, punctated, diſtinct leaves; and purple flowers.

[20]MESEMBRYANTHEMUM, *Glomeratum.*

*Glomerated Meſembryanthemum.*] Hath a ſhrubby, ſucculent, diffuſe, paniculated ſtalk; taper, trigonal, compreſſed, incurved, punctated leaves; and numerous purple flowers in conglomerated panicles.

[21]MESEMBRYANTHEMUM *Loreum.*

*Loreated Meſembryanthemum.*] Hath a looſe, pendulous, ſucculent ſtalk; ſemi-cylindrical, long, recurved, connate leaves, in cluſters, having the interior part of the baſe gibbous; and reddiſh purple flowers.

[22]MESEMBRYANTHEMUM *Filamentoſum.*

*Filamentoſe Meſembryanthemum.*] Hath a pendulous, looſe, ſucculent ſtem, dividing into hexagonal branches; triquetrous, ſlightly-punctated leaves, almoſt connate at their baſe, with rough angles; and ſmall-petaled, obſolete-purple flowers.

[23]MESEMBRYANTHEMUM *Acinaciforme.*

*Scymitar-leaved Meſembryanthemum.*] Hath a looſe, procumbent ſtalk; ſcymitar ſhaped, ſpotleſs, connated leaves, having angular rough keels; and purple flowers, with ſpear-ſhaped petals.

[24]MESEMBRYANTHEMUM *Micans.*

*Glittering Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent, rough ſtem; ſub-cylindrical, pimply, ſilvery, glittering, diſtinct leaves; and orange coloured flowers.

[25]MESEMBRYANTHEMUM *Roſtratum.*

*Roſtrated, or Heron's bill Meſembryanthemum.*] Is acaulis, or without ſtalks; ſemi-cylindric, connated leaves, having the outſide ſet with tubercles; and yellow flowers.

[26]MESEMBRYANTHEMUM *Corniculatum.*

*Corniculated, or Horned Meſembryanthemum.*] Hath a looſe, creeping, ſucculent ſtalk; triquetrous ſemi-cylindric, horned, rough punctated, connate leaves; and yellow and orange-coloured flowers, with ten ſtyles.

[27]MESEMBRYANTHEMUM *Bicolorum.*

*Bicolor, or Two-coloured Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent ſtem; awl-ſhaped, ſmooth, punctated, diſtinct leaves; and two-coloured flowers, *i. e.* purple without and yellow within.

[28]MESEMBRYANTHEMUM *Glaucum.*

*Glaucous, or Grey-leaved Meſembrianthemum.*] Hath an erect, ſhrubby, ſucculent ſtem; three-ſquare, acute, punctated, diſtinct leaves; and yellow flowers, having the calycinal ſolioles oval-cordate-ſhaped.

[29]MESEMBRYANTHEMUM *Ringens.*

*Ringent Meſembryanthemum, or Dog's chap Ficoides.*] Is ſub-acaulis, or almoſt without ſtalk; thick, three-cornered, ciliate, indented, dotted leaves; and yellow flowers.

*Variety.*] Cat's-chap *Meſembryanthemum.*

[30]MESEMBRIANTHEMUM *Difforme.*

*Deformed-leaved Meſembryanthemum.* Is acaulis; having thick, deformed, dotted, connated leaves; and yellow flowers.

[31]MESEMBRYANTHEMUM *Dolabriforme.*

*Axe-leaved Meſembryanthemum.*] Hath low, procumbent, ſucculent ſtalks; axe-ſhaped, punctated leaves; and yellow flowers, opening on nights.

[32]MESEMBRYANTHEMUM *Expanſum.*

*Expanded Meſembryanthemum.*] Hath low, looſe, procumbent, ſucculent ſtalks; ſpear-ſhaped, plane, expanded, impunctated, or unſpotted, diſtinct leaves, oppoſite and alter-

nate, at a diſtance; and yellow flowers, white within.

[33]MESEMBRYANTHEMUM *Linguiforme.*

*Tongue-leaved Meſembryanthemum.*] Is acaulis, or without ſtalk; tongue-ſhaped, tall, impunctated, ſmooth leaves, having very thick margins; and large yellow flowers, with ten ſtyles.

*Varieties.*] With broad leaves—with narrow leaves—long-leaved.

[34]MESEMBRYANTHEMUM *Veruculatum.*

*Veruculiforme-leaved Meſembryanthemum.*] Hath a ſhrubby, firm, ſucculent ſtalk, three-ſquare-cylindric, bowed, acute, unſpotted, pellucid, diſtinct leaves, connate at the baſe; and yellow flowers in cluſters.

[35]MESEMBRYANTAEMUM *Tortuoſum.*

*Tortuoſe Olive-leaved Meſembryanthemum*] Hath a low, looſe, procumbent, ſucculent ſtalk; plane, oblong-oval, ſub-papilloſe, connate leaves, in cluſters; white flowers with ſaffron middles, having triphyllous two-horned cups.

[36]MESEMBRYANTHEMUM *Albidum.*

*White-leaved Meſembryanthemum*] Is acaulis, having three-ſquare, thick, firm, entire leaves, of a whitiſh colour; and large golden-yellow flowers.

[37]MESEMBRYANTHEMUM *Pugioniforme.*

*Dagger-leaved Meſembryanthemum.*] Hath a ſhrubby, ſucculent ſtalk; awl-ſhaped, triquetrous, very long, ſpotleſs, alternate leaves; and large, golden-yellow flowers, with ten ſtyles.

All theſe thirty-ſeven ſpecies of *Meſembryanthemum*, being natives of Africa, in this country they require ſhelter of a green-houſe, &c. in winter; they are all ſucculent in ſtalk, branch, and leaves, as before ſuggeſted. The firſt of which is an annual of great ſingularity; all the others are perennial, and moſtly durable in ſtem and foliage; thoſe deſcribed ſhrubby, riſe with firm ſtems of different heights, often branchy; the others deſcribed pendulous, have looſe ſtraggling ſtems and branches, inclining to the ground; and the acaulis ſorts have no ſtalks at all: their leaves are univerſally very thick, ſucculent, fleſhy, and of ſo many various ſhapes, ſituations, directions, and many of them curiouſly punctured, or dotted, with tranſparent points; others papilloſe, or covered with pellucid pimples, as in each reſpective deſcription, that, together they exhibit a ſingularly agreeable variety at all times of the year, and merit a place in every curious green-houſe collection. They are alſo very ornamental in their flowers, which in different ſorts appear at different ſeaſons of the year, as in ſpring, ſummer, autumn, and winter, and many of the ſorts ſo floriferous as to appear covered with their flowers.

The flowers of all the ſpecies are univerſally monopetalous, but each is multifid or finely divided almoſt to the bottom, into numerous narrow ſegments, in ſeveral ſeries, all uniting at the baſe, appearing like ſome ſorts of marigolds, and which in their native ſoil, Africa, are ſucceeded by abundance of fruit, ſhaped ſomewhat like a fig, hence the name Fig-Marigold *(Ficoides)*.

The *Meſembryanthemum Cryſtallinum* is a very tender annual while young; is raiſed annually from ſeed in ſpring, by aid of hot-beds, until June, when it will endure the open air till October, and then periſhes; though if in autumn it is placed in a hot-houſe, it will often live all winter. It is commonly planted in pots, to move to different parts occaſionally; but if planted in the full ground, it grows conſiderably ſtronger, even to luxuriancy; it, however, when confined in pots, flowers the moſt abundantly.

All the perennial ſorts are of the temperature of green-houſe plants, ſo muſt be kept conſtantly in pots to move to that conſervatory in winter; though ſome of the ſhrubby kinds are hardy enough to ſucceed all winter under a garden-frame, and ſometimes in a warm border againſt a ſouth wall; it is, however, proper to allow the principal part the winter's ſhelter of a green-houſe.

As all the ſorts are of a ſucculent nature, always replete with moiſture, they ſhould be potted in a poor, light, dry earth; if ſandy, or of a rubbiſhy nature the better; however, any common light ſandy earth, free from dung, is proper, or a compoſt of light dry materials. See COMPOST.

They require ſhelter from October till May or June, muſt have but little water in winter, but frequent in ſummer, when in the open air in dry weather.

*Propagation and general Culture.*

Their propagation is, the firſt ſort by ſeed annually in ſpring in a hot-bed; and all the others by cuttings of their ſtalks or branches, in ſummer in the common ground; though their rooting may be facilitated by aid of artificial heat: obſerve the following directions for each ſort.

Firſt Species.—This ſort is raiſed annually from ſeed ſowed in March or beginning of April, in a hot-bed under frame and glaſſes, as directed for the *Amarantus Tricolor*, *Celoſia Criſtata*, or Cock's-Comb, Globe Amaranthus,

ranthus, and other tender annuals, as one bed may raiſe the whole; obſerving to mould the hot-bed with fine rich light earth, that is perfectly dry, ſix inches thick; the ſeed may then be ſowed in the earth of the bed in very ſhallow drills, covering it ſcarcely a quarter of an inch deep; or may be ſowed in pots of fine mould, the ſame depth, plunging the pots in the earth of the hot-bed; the plants will ſoon riſe, but they come up very weak, and advance very ſlowly at firſt, as well as being exceedingly tender, and impatient of cold and moiſture in their infant growth; indulge them, however, with freſh air daily at all opportunities, as directed in the culture of the above named annuals; likewiſe allow them water occaſionally, but uſe great caution in this, and always apply it as moderate and light as poſſible. When the plants are an inch or two high, prick out ſome of the ſtrongeſt, either in the ſame hot-bed, or in a freſh one, three inches apart, or in ſmall pots ſingly, giving very light waterings, and ſhade from the mid-day ſun, till freſh-rooted; here to remain a month, or thereabouts, continuing the admiſſion of air, as above, and ſupport the heat of the bed; and then if they are removed with balls into pots, and placed in a new hot-bed, it will forward them greatly; at which time thoſe intended to remain finally in pots, ſhould be planted in proper ſized ones (twenty-fours), to remain, which plunge in the hot-bed: let the whole remain in the bed under the frame and glaſſes. Continue the above management until the middle or latter end of June, then remove them to the full air; ſome to remain in the pots, others may be turned out with balls into the open borders, where they will grow freely, and ſpread their branches abundantly all around upon the ground, two or three feet every way.

As to future culture, thoſe in pots muſt be frequently watered in dry weather; but thoſe in the borders require no other care than to be kept clean of weeds, ſuffering their branches to ſpread about upon the ground.

To ſave good ſeed of this ſpecies, ſome of the potted plants ſhould, when in full bloom, be placed either in a frame to have occaſional ſhelter of the glaſſes in very wet weather and cold nights, whereby they will ripen ſeeds; or, if placed in a ſtove, or in a glaſs-caſe near the front, where they may have the free air, but defended as above, they will ripen ſeed more effectually; they, however, in fine dry warm autumns, will ſometimes ripen ſeed without the above precaution, but this is not to be depended on.

Perennial Sorts.—The propagation of all the perennial ſpecies, is effected by cuttings of the ſtalks and branches, any time from April till July; obſerving thoſe planted before the beginning of June ſhould generally be planted in pots, and plunged in a hot-bed, but thoſe in June or July, ſucceed in the open ground.

In chuſing the cuttings, obſerve to cut them off from about two or three to five or ſix inches long, according to the nature of the plants, and ſtrength of the ſhoots; obſerving to diveſt them of the lower leaves, if any, and then, previous to planting, lay the cuttings in a dry airy room, for ſome time, to heal over the wound, or cut part, as is neceſſary to all ſucculent cuttings; ſome will require to lie only three or four days, others of the moſt ſucculent nature, eight or ten; for the cut part muſt be healed, otherwiſe the moiſture iſſuing therefrom would be apt to rot the cuttings after being planted.

The cuttings being ready, then having a compoſt of light dry ſoil, either in pots or in the full ground, plant the cuttings therein, from about one inch to two or three deep, according to their length, cloſing the earth firmly about each, and directly give a little water; then thoſe in pots, if early in the year, may be plunged in a hot-bed, or in the bark-bed; but if in ſummer, may plunge them in a dry border; obſerving to allow all of them occaſional ſhade in ſunny days, from about ten until three or four o'clock, till they are rooted, eſpecially thoſe in the open air, by a covering of mats, giving ſprinklings of water in dry weather, once or twice a week; remarking that if heavy rains fall, it is proper to ſhield theſe kinds of cuttings from it as much as poſſible, but let them enjoy moderate ſhowers.

In ſix weeks, or a little more or leſs time, the cuttings will be rooted, and in a growing ſtate, when thoſe that were ſtruck in the full ground muſt be potted, thoſe already in pots, may remain in the ſame; and all of them in both caſes, placed in a ſheltered ſituation till October, then removed into the green-houſe; or a good garden-frame furniſhed with glaſſes for the winter.

As to their general culture, it is the ſame as for other ſucculents of ſimilar temperature; giving them ſhelter every winter, from October

tober until May, or beginning of June, and from thence to the end of ſummer place them in the open air: water them ſparingly in winter, but freely in ſummer in dry hot weather; and ſhift them annually into larger pots.

GREEN-HOUSE PLANTS.

MESPILUS, Medlar.

This genus conſiſts of deciduous fruit-trees and flowering ſhrubs, and a very ornamental ever-green; all hardy, of upright growth, and garniſhed with ſpear-ſhaped, and oblong-oval foliage, and quinquepetalous flowers; in ſome ſingly, but in the greater part in bunches, from the ſides and ends of the branches; ſucceeded by globular, baccaceous, eatable fruit, in ſome ſorts as large as moderate apples.

Claſs and order, *Icoſandria Pentandria.*

*Characters.*] CALIX, is monophyllous, divided into five concave, patent, permanent ſegments. COROLLA, five roundiſh concave petals, inſerted into the calix. STAMINA, twenty or more filaments inſerted into the calix, and ſimple antheræ. PISTILLUM, a roundiſh germen below the corolla, five erect ſtyles, and capitated ſtigmas. PERICARPIUM, a globular, umbilicated bacca, crowned by the connivent calix, and contains five gibbous, ſtoney ſeeds.

In this genus old botaniſts arranged the hawthorn, cockſpur-haw, azarole, and ſome other ſpecies, now of the genus *Cratægus*, &c. whoſe flowers are alſo icoſandrous, but have only two ſtyles, whereas in all the proper ſpecies of *Meſpilus*, now under conſideration, the flowers have five ſtyles, which is an obvious generic diſtinction between theſe two genera.

The real ſpecies, therefore, of this genus, are the following ſeven, ſix deciduous, and one ever-green, all of the tree and ſhrub kind.

*Deciduous Kinds.*

The firſt of theſe (common Medlar) is conſidered principally as a fruit-tree, alſo ſometimes for variety; the others chiefly as flowering ſhrubs for ornament.

[1]MESPILUS *Germanica.*

*German Meſpilus, or Common Medlar.*] Riſes with a deformed tree-ſtem, branching irregularly fifteen or twenty feet high; ſpear-ſhaped leaves, downy underneath; and large cloſe-ſitting, white flowers, ſingly from the ſides of the branches; ſucceeded by large roundiſh brown fruit, the ſize of middling apples, ripen in October, but not eatable till beginning to decay.

*Varieties.*] Common great German Medlar—ſmaller Nottingham Medlar—pear-ſhaped Italian Medlar.

This ſpecies and varieties are all cultivated in the Engliſh gardens for the fruit, but the German or Dutch Medlar, and the Nottingham kind, are the moſt common; and the latter of which two, though a ſmaller fruit, is rather preferable for richneſs and poignancy of flavour. Remarking of all theſe kinds of fruit, that they are never eatable until they begin to rot; for when firm and ſound, are of a ſingularly auſtere diſagreeable taſte, yet having lain ſome time after being gathered, till they begin to aſſume a ſtate of decay, and become ſoft, they acquire a delicious flavour, extremely agreeable to many, to others altogether unpalatable.

All the ſorts ripen in the latter end of October, or beginning of November, when being gathered, ſome ſhould be laid in moiſt bran, in ſeveral layers, to forward their decay, others on ſtraw in the fruitery; thoſe in the bran will begin to be ready for uſe in about a fortnight, and thoſe laid on ſtraw will come gradually forward in ſucceſſion.

[2]MESPILUS *Arbutifolia.*

*Arbutus-leaved Meſpilus.*] Meſpilus with a ſhrubby ſtem, branching erectly five or ſix feet high; lanceolate, crenated, alternate leaves, downy underneath; and from the ſides and ends of the branches, ſmall white flowers in cluſters; ſucceeded by ſmall, roundiſh, purple fruit, like haws.

[3]MESPILUS *Amelanchier.*

*Amelanchier, or Shrubby Medlar, with black fruit.*] Riſes with ſeveral ſhrubby, ſlender, hairy ſtems, branching moderately about four feet high, having purpliſh branches; oval, ſerrated leaves, downy underneath; and ſmall white flowers, in cluſters at the ends of the branches; ſucceeded by ſmall black fruit.

[4]MESPILUS, *Chamæ-Meſpilus.*

*Chamæ-Meſpilus, or Dwarf Medlar, commonly called Baſtard Quince.*] Hath a ſhrubby, ſlender, ſmooth ſtem, branching weakly four or five feet high, having purpliſh branches; oval, ſerrated, ſmooth leaves, on long foot-ſtalks; and from the axillas, purple flowers, collected into round heads, with narrow, purpliſh, deciduous bracteæ; ſucceeded by ſmall red fruit.

[5]MES-

[5]MESPILUS *Cotoneaſter.*

*Cotoneaſter, commonly called Dwarf Quince.*] Riſes with a ſhrubby, ſmooth ſtem, branching four or five feet high, the branches ſlender and reddiſh; oval entire leaves, on ſhort foot-ſtalks; and from the axillas, ſmall, cloſe-ſitting, purple flowers, two or three together; ſucceeded by ſmall, roundiſh, bright-red fruit.

[6]MESPILUS *Canadenſis.*

*Canada Snowy Meſpilus.*] Hath a ſhrubby, ſmooth ſtem, branching four or five feet high, having ſmooth, purpliſh branches; oval-oblong, ſerrated, ſmooth leaves, on long foot-ſtalks; and all the branches terminated by cluſters of ſnowy-white flowers; ſucceeded by ſmall, purpliſh fruit, like haws.

*Ever-green Kind.*

[7]MESPILUS *Pyracantha.*

*Pyracantha, or Ever-green Thorn*] Riſes with a ſhrubby, ſpinous ſtem, branching diffuſely twelve or fourteen feet high, the branches ſlender and flexible, with a dark-greeniſh bark, armed with long ſharp ſpines; ſpear-ſhaped-oval, crenated, ever-green leaves; and all the ſhoots terminated by numerous cluſters of whitiſh flowers; ſucceeded by large bunches of beautiful red berries, remaining all winter, and exhibiting a very ornamental appearance.

All theſe ſeven ſpecies of *Meſpilus* are of the tree and ſhrub kind; the firſt ſix ſorts are deciduous, the ſeventh an ever-green, the leaves univerſally ſimple; thoſe of the *Meſpilus Germanica* very large; the others moſtly of moderate ſize; and which in moſt of the ſorts grows upon ſhort foot-ſtalks. They all flower abundantly every ſummer, the flowers univerſally hermaphrodite, and conſiſt each of five large, roundiſh petals, twenty ſtamina, and five ſtyles; and all ſucceeded here by plenty of fruit of the berry kind; ſee the *Characters*. The fruit of ſome is as large as middling apples, as before obſerved, as in the common Medlars; others ſcarcely the ſize of haws.

They are all very hardy, and ſucceeed in any common ſoil and ſituation, and their propagation and culture is very eaſy.

With reſpect to their uſe in gardens, the firſt ſort and varieties is cultivated as a fruit-tree, principally as ſtandards, ſometimes alſo as eſpaliers for variety; and are alſo often introduced into the ſhrubbery plantation to diverſify the collection; all the other ſix ſpecies are very proper furniture for any ornamental plantation, where they will effect variety very agreeably with their different foliage; and their flowers make a fine appearance, as alſo their fruit in autumn and winter, which, if not devoured by birds, remain long on the branches, and afford a fine variety in thoſe ſeaſons; obſerving to diſpoſe the deciduous kinds in aſſemblage, principally with others of that tribe; and the ever-green ſort alſo chiefly with thoſe of its own nature; arranging each ſort according to its gradation of height; but as the *Pyracantha* being remarkably ornamental, both as an ever green, and ſingularly beautiful in its numerous cluſters of fine red berries, covering the branches in winter, it in particular ſhould have a conſpicuous ſituation; this ſort, however, being rather of flexible growth, is moſt commonly trained againſt walls or the fronts of houſes, both for the ſupport of its flexible branches, and that it may exhibit its berries more ornamentally; it, however, may alſo be trained as a ſtandard, like the other ſorts, in the open ſhrubbery, and all of them ſuffered to branch out into ſpreading heads.

When it is deſigned to have any of the common Medlars as fruit-trees, they may be trained either as dwarfs, for dwarf ſtandards, or for eſpaliers, or trained as half or full ſtandards; and managed in either of theſe modes of training nearly as other fruit-trees, particularly the apple and pear; and are raiſed either by ſeed, by graſting, or by budding, but either of the two latter methods are the moſt certain for continuing the ſorts without variation; obſerving after ſhortening their firſt ſhoots from the graft or bud, where it ſhall ſeem neceſſary, to force out a proper ſupply of wood to form a head; train the branches afterwards principally at full length, and let the ſtandards branch out in their own way.

*Propagation and Culture.*

All the ſorts are eaſily raiſed from ſeeds, layers, and by graſting and budding.

By Seed—By this method all the ſorts may be propagated plentifully in the common ground; obſerving, however, that it is moſt eligible to raiſe the *Medlars* principally by graſting or budding, to continue the ſorts; but in reſpect to ſowing the ſeed, this ſhould generally be ſowed in autumn, in a bed of common earth: they uſually lie a year, or more, before they germinate, that is, like haws and holly-berries, &c. they rarely come up before the ſecond ſpring; when water them frequently in dry weather; and in autumn

tumn or ſpring following, the largeſt ſeedlings may be thinned out and planted in nurſery-rows, two feet by one aſunder; and in another year plant out all the reſt in the ſame manner; and in three or four years, they will be proper for the garden or ſhrubbery.

By Layers —In autumn, or any time from that ſeaſon until February or March, lay the young branches by the common method, they will be properly rooted by autumn following, when tranſplant them in nurſery-rows like the ſeedlings.

By Grafting and Budding.—Either of theſe methods ſhould generally be practiſed for raiſing the common Medlars, for they are apt to vary from ſeed; but all the other ſorts may alſo be readily propagated by the ſame methods; obſerving, that the ſtocks generally uſed on which to work moſt of the ſorts is the *White Thorn, i. e. Cratægus Oxyacantha*, raiſed from ſeed, as directed under that article; but the pear-ſtock is rather to be preferred for the common Medlars, when intended for fruit-trees; and the work of grafting and budding them is in the uſual way, low in the ſtock to form dwarfs; and for half, or full ſtandards, it may alſo either be performed low in the ſtock, and train the firſt-ſhoot for a ſtem, or let the ſtock form a ſtem, and work them at from about three or four to five or ſix feet height. See GRAFTING and INOCULATION.

Obſerve that thoſe intended for fruit-trees, whether dwarfs, or half or full ſtandards, they, with reſpect to training, ſhould, for dwarfs, have the firſt ſhoots from the graft or bud headed down ſhort in ſpring, if neceſſary, to force out a proper ſupply of bottom-branches, which train as for other dwarf fruit-trees, either for ſtandard-dwarfs or eſpaliers; or if for half or full ſtandards, that if worked low in the ſtock, train the firſt ſhoot of each for a ſtem, then top it at the proper height, to force out laterals to form the head; but if worked high in the ſtock, the firſt ſhoots may either be ſhortened or ſuffered to grow as it ſhall ſeem proper, according to the natural diſpoſition of the leading ſhoot, with reſpect to its furniſhing lateral branches; remarking, after this training the firſt year or two, to give the tree its firſt proper formation, you are to deſiſt from any general ſhortening of the branches, practiſing it only occaſionally to particular ſhoots to procure more wood, if neceſſary, to fill any vacancy, or to reduce any irregular growth, or to cut off dead parts; but otherwiſe train the branches principally at full length, and let the ſtandards aſſume nearly their own natural way of branching. See DWARF-TREES, ESPALIERS, and STANDARD-TREES, &c.

MIMOSA, Senſitive Plant, &c.

This genus compriſes ſhrubby and herbaceous plants, but moſtly of the ſhrub kind, ſome trailing, others erect, all natives of the Indies, &c. retained here in ſtoves as great curioſities, particularly for the very ſingular ſenſibility of the leaves of ſome ſorts, which on being touched, ſuddenly recede, contract and fall down in a very wonderful manner: all of them garniſhed with pinnated leaves, and monopetalous, funnel-ſhaped, five-parted, polygamous flowers at the axillas and ends of the branches in cluſters and ſpikes.

Claſs and order, *Polygamia Monœcia.*

*Characters.*] CALIX, is monophyllous, ſmall, and quinquedented. COROLLA, is monopetalous, funnel-ſhaped, and five-parted at the brim. STAMINA, many long capillary filaments, and incumbent antheræ. PISTILLUM, an oblong germen, ſhort filiforme ſtyle, and truncated ſtigma. PERICARPIUM, a long pod, having tranſverſe partitions, containing many roundiſh ſeeds.

The name *Mimoſa*, of this genus, ſignifies mimick, originating from the ſenſibility of the leaves, which by their motion mimick, or imitate, as it were, the motions of animals.

To this genus Linnæus joins many of the *Acacias*, and it compriſes upwards of forty different ſpecies; though not more than a quarter of them are common in the Engliſh gardens; or that poſſeſs any particular merit either for curioſity or ornament, and none for uſe. Of the ſorts cultivated here in our ſtoves, &c. ſome are of the ſhrub and tree kind, and two or three are herbaceous perennials and annuals; are moſtly of the ſenſitive kinds, except the *Acacia* ſorts, which are motionleſs, as expreſſed under their proper heads, i. e. ſenſitive and humble kinds, and ſenſeleſs kinds. The former of which are exceedingly curious plants in the very ſingular circumſtance of their leaves receding rapidly from the touch; for the leaves being winged, each compoſed of numerous ſmall lobes, all of which on being touched, haſtily run up cloſe together; and in ſome ſorts the foot-ſtalks and all is affected, ſo as inſtantly to fall downward, as if faſtened by hinges.

*Shrubby*

*Shrubby, Senſitive, and Humble Kinds.*

They have all winged leaves, each wing of many ſmall pinnæ; ſome only contract the lobes of the leaves and pinnæ at the touch; others not only contract every part of their leaves, but which, together with their foot-ſtalks, ſuddenly drop downward; and for diſtinction ſake, the former are called Senſitive *Mimoſas*, and the latter Humble Senſitives; but the leaves of both ſorts ſoon recover their uſual poſition.

[1]MIMOSA *Senſitiva.*

*Common Senſitive Humble Plant.*] Riſes with an under-ſhrubby prickly ſtem, branching ſix or eight feet high, armed with crooked ſpines; conjugated, pinnated leaves, with bijugated partial lobes, or wings, having the inner ones the leaſt, each leaf on a long foot-ſtalk; and at the ſides and ends of the branches many purple flowers in roundiſh heads; ſucceeded by broad, flat, jointed pods, in radiated cluſters.

This is ſomewhat of the humble-ſenſitive kind; the leaves, foot-ſtalks and all, recede from the touch, though not with ſuch facility as in ſome of the following ſorts.

[2]MIMOSA *Pudica.*

*Baſhful Humble Plant.*] Riſes with an under-ſhrubby, declinated, prickly ſtem, branching two or three feet around, armed with hairy ſpines; pinnated, digitated leaves, each leaf being of five or more long folioles, attached by their baſe to a long foot-ſtalk, and ſpread out above like the fingers of a hand; and at the ſides and ends of the branches roundiſh heads of greeniſh white flowers; ſucceeded by ſmall, jointed, prickly pods.

This is truly of the humble ſenſitive kind, for by the leaſt touch the leaves inſtantly recede, contract cloſe, and, together with the foot-ſtalk, quickly decline downward, as if aſhamed at the approach of the hand.

[3]MIMOSA *Pernambucana.*

*Pernambuca Slothful Mimoſa.*] Hath under-ſhrubby, procumbent, unarmed ſtems, branching two or three feet around; bipinnated leaves, of three or four pair of ſhort, winged foliola; and at the axillas drooping ſpikes of pentandrous flowers, the lower ones caſtrated.

This ſort receding very ſlowly from the touch, only contracting its pinnæ a little when ſmartly touched; hence the name Slothful Mimoſa.

[4]MIMOSA *Aſperata.*

*Rough Senſitive Mimoſa.*] Hath a ſhrubby, upright, prickly, hairy, rough ſtem, branching four or five feet high, armed with ſhort, broad, whitiſh ſpines; bipinnated, prickly leaves, of five or ſix pair of foliola, or wings, arranged oppoſite, having two thorns between each pair; and at the upper axillas globular heads of purple flowers; ſucceeded by ſhort, flat, jointed pods, in cluſters, ſpreading each way like a radius.

This is only moderately ſenſitive in its foliola, but not in the foot-ſtalks.

[5]MIMOSA *Punctata.*

*Punctated Senſitive Mimoſa.*] Riſes with a ſhrubby, upright, taper, punctated or ſpotted, unarmed ſtem, branching erectly five or ſix feet high; bipinnated leaves, of four or five pair of long, winged folioles, having each about twenty pair of pinnæ; and at the axillas and termination of the branches oblong ſpikes of yellowiſh decandrous flowers, the inferior ones caſtrated; ſucceeded above by oblong ſeed-pods.

This ſort, though naturally ſhrubby and perennial in its native ſoil, yet in this country it ſometimes decays in winter.

It is only ſenſitive in the foliola, but quick in the motion.

*Herbaceous Senſitive and Humble Kinds.*

Of theſe ſorts two are perennial of the trailing kind; and one is annual, of ſomewhat erect growth; have all winged leaves, with the wings formed of many ſmall pinnæ.

[6]MIMOSA *Viva.*—(*Perennial.*)

*Lively Senſitive Mimoſa.*] Hath herbaceous, trailing, unarmed, repent ſtems, very branchy, ſpreading widely around, rooting at the joints as they advance; conjugated pinnated leaves, with quadrijugated, roundiſh, partial lobes, or wings; and at the axillas globular heads of yellowiſh flowers; ſucceeded by ſhort, flat, jointed pods.

This ſpecies is only ſenſitive in the foliola, but is the moſt lively of that kind, it being ſo ſuſceptible that all the foliola recede rapidly from the leaſt touch, whereby it has the diſtinctive appellation of vivacious, or lively *Mimoſa.*

[7]MIMOSA *Quadrivalvis.*—(*Perennial.*)

*Quadrivalve Humble Mimoſa.*] Hath herbaceous, ſlender, quadrangular, prickly ſtems, branching and ſpreading all around, armed with recurved ſpines; bipinnated leaves of

two or three pair of winged lobes, having each many pinnæ; and at the axillas globular heads of purple flowers, ſucceeded by quadrivalvular pods.

This is of the humble ſenſitive kind, both leaves and foot-ſtalks recede from the touch.

[8]MIMOSA *Plena—(Annual).*

*Double-flowered Senſitive annual Mimoſa.*] Riſes with an herbaceous, erect, round, unarmed ſtem, cloſely branching and ſpreading every way, three or four feet high; bipinnated leaves of four or five pair of winged lobes, of many pairs of pinnæ; and at the axillas and termination of the branches ſpikes of yellow pentandrous flowers, the lower ones double; ſucceeded by ſhort, broad pods.

This annual is only ſenſitive in the foliola, but extremely ſuſceptible of the touch or air.

*Shrubby Inſenſible Kinds.*

Theſe are of the *Acacia* kind, formerly a diſtinct genus, but now all ſpecies of *Mimoſa*; but their leaves are deſtitute of motion or ſenſibility at the touch; there are about three noted ſpecies in the Engliſh gardens, all for the ſtove.

[9]MIMOSA *Cornigera.*

*Horned Mexican Mimoſa, commonly called Great Horned Acacia.*] Hath a ſhrubby, upright, deformed ſtem, branching irrregularly, armed with very large, horned-like, white ſpines, by pairs, connated at the baſe; bipinnated leaves thinly placed; and flowers growing in ſpikes.

This ſpecies is eſteemed a curioſity for the oddity of its large ſpines, reſembling the horns of animals, and which are often variouſly wreathed, twiſted, and contorted.

[10]MIMOSA *Farneſiana.*

*Farneſian Fragrant Acacia.*] Hath a ſhrubby ſtem, branching many feet high, armed with diſtinct ſpines; bipinnated leaves, having eight pair of partial lobes, or wings; and globular, cloſe-fitting ſpikes of yellow ſweet-ſcented flowers.

[11]MIMOSA *Nilotica.*

*Nilotic True Ægyptian Acacia.*] Hath an upright tree-ſtem, branching many feet high; armed with ſpreading ſpines; bipinnated leaves; and globular ſpikes of flowers, having foot-ſtalks. From the exſudation of the leaves of this ſort, is procured the drugs called *Succus Acaciæ* and Gum-arabic.

Theſe eleven ſpecies of *Mimoſa* are the moſt noted ſorts in the Engliſh gardens; all the ſhrubby kinds are durable in root, ſtem, and branches; thoſe of the perennial herbaceous kinds, are alſo often abiding; but the annual ſort always periſh root and branch at the approach of winter. They are all natives of the Indies, and in this country require the continual ſhelter of a hot-houſe, or of a hot-bed of ſimilar temperature under frames and glaſſes; though they can hardly be ſupported alive in winter unleſs placed in a ſtove; ſo all the ſorts muſt conſtantly be kept in pots, and placed principally in that department, eſpecially during the winter; nor will they ſucceed well in the open air in ſummer, except about a month during the greateſt heat; but the ſenſitive and humble kinds, if expoſed to the open air even in the hotteſt days will be deprived of their ſenſibility during the time they remain ſo expoſed, therefore ſhould always be kept under glaſſes, in a ſtove if poſſible; or in default of ſuch a convenience, the plants might be raiſed from ſeed in ſpring in any common hot-bed under frames, &c. as directed for tender annuals, and continued conſtantly under the glaſſes, and thereby will afford pleaſure all ſummer by the oddity of their ſenſitive foliage; however to have them to remain in perfection the year round, ſome muſt be continued always in a ſtove, as before obſerved, for the warmer they are kept, the ſtronger will be their ſenſible quality.

The ſenſitive and humble kinds in particular, frequently flower in this country, and produce ſeeds. The *Mimoſa Farneſiana* is alſo often very floriferous here, which are very fragrant; the flowers of all are, ſeparately, but ſmall, but generally grow in bunches; each flower is monopetalous and funnel-ſhaped, with many ſtamina. See the *Characters.*

The ſenſitive and humble plants are in great eſtimation among the curious for the ſingular ſenſibility lodged in their leaves; which has two kinds of motion, the one occaſioned by the action of warm nouriſhing vapours; the other artificial, in conſequence of being touched or ſhaken; that with whatever body it is touched or irritated, either by the hand, a ſtick, or the leaſt wind blowing, the wings of the leaves ſuddenly cloſe, and the foot-ſtalks fall down; but they all ſoon recover their proper poſition, eſpecially in a warm ſtove.

It

It is remarkable, the ſenſibility of ſome reſide particularly in the articulation or joinings of the lobes of the leaves to the partial foot-ſtalks, as in the ſimple ſenſitives; in others both in the joinings of the lobes, and in the articulations of the mid-rib, to which they are attached, as alſo to the main or common foot ſtalk, as in the humble ſenſitive kind.

The motion of theſe plants is owing to a ſtrong contraction; each foot-ſtalk ſeems to to terminate with a kind of joint, on which the lobes and leaves turn in all directions with ſurpriſing facility, and the main foot-ſtalk ſeems attached to the branches by a joint, ſo as to turn up and down as by a hinge.

In the experiments of trying the ſenſibility of theſe plants, that in touching the upper leaves, if in contracting they fall and touch thoſe below them, thoſe will alſo all contract and fall, ſo that as one touch another they will continue falling one after another for a conſiderable time in a curious manner.

The time which the leaves, &c. require to recover themſelves, after falling by any touch or irritation, is according to the vigour of the plant, hour of the day, ſereneneſs of the atmoſphere, and temperature of the heat of the ſtove, &c. ſo are often from about ten or fifteen minutes to an hour or more, before they are fully reinſtated in their former proper poſitions.

It is remarkable that the plants each evening naturally contract themſelves, and expand again in the morning.

*Propagation and Culture of all the Sorts.*

The propagation of all the ſorts both ſenſitives and *Acacias*, is by ſeed in ſpring in a hot-bed, or in the bark-bed in the ſtove; and ſome of the ſenſitive kinds alſo by layers and cuttings.

By Seed.—It is ſold at the nurſeries and ſeed-ſhops. Sow it in pots of light rich mould, covering it with fine earth a quarter of an inch deep, and plunge the pots in the hot-bed, if in a common hot-bed under frames and glaſſes; manage them nearly as directed for tender annuals, ſuch as the *Amaranthus Tricolor*, and others of that quality; and if in a bark-bed in the ſtove, very little trouble is required: obſerving to give moderate ſprinklings of water, and when the plants are two or three inches high, prick them ſingly in ſmall pots, which plunge alſo in the hot-bed, &c. giving water and occaſional ſhade till rooted, repeating the waterings frequently, and continue the plants in the hot-bed under glaſſes, or plunged in the bark-bed of the ſtove, being both neceſſary to facilitate their growth, preſerve them in vigour, and encreaſe the ſenſibility of the ſenſitive kind; allowing air in common with the other plants in the bed. Remarking, that to preſerve the perennial ſorts, both ſhrubby and herbaceous, they muſt be kept in the ſtove all winter, and indeed principally the year round, when they will be of ſeveral years duration, flower in ſummer, and ripen ſeeds in autumn, particularly ſome of the ſenſitive kinds.

But in want of a ſtove, as before hinted, thoſe who are curious to have ſome ſenſitive plants, may nevertheleſs have the pleaſure of them in ſummer, by aid of a common dung hot-bed under frames and glaſſes, but not in winter; that is, raiſe ſome plants, either of the annual ſort or any of the other kinds, by ſeed in ſpring, in a hot-bed under a frame, &c. as above directed, keeping up the heat of the bed until the middle of June, and continue the plants always under the frame, tilting one end of the lights a little, occaſionally in warm days to admit freſh air; and as the plants riſe in height raiſe the frame at bottom, to allow them full room to grow; or about Midſummer, or ſoon after, ſome of the low ſpreading kinds may be turned out with balls, or plunged in their pots into a warm ſunny border, and covered with large hand-glaſſes, which may be lifted off occaſionally juſt to view the plants. By thoſe methods the plants may be preſerved through the ſummer in their ſenſitive quality, tho' not equal in perfection to thoſe in ſtoves; nor can they be preſerved alive in winter out of a ſtove.

By Layers.——Any of the ſhrubby kinds that afford ſpreading branches may be layed any time in ſummer, in pots plunged contiguous in the bark-bed, where they will readily take root, and be ready to pot off ſingly in autumn.

By Cuttings.——The ſenſitive and humble kinds often branch out profuſely, ſo as to furniſh plenty of young ſhoots in ſummer, of which take cuttings, plant them in pots, and plunge them in the bark-bed, they will readily take root and form proper plants.

But after all, ſeedlings generally form the beſt plants; however, any of the other two methods is eligible in default of ſeed.

With reſpect to the general culture of all the ſpecies, they muſt always be kept in pots; and to preſerve them all the year, muſt be placed in the ſtove, plunged chiefly in the

bark-bed, giving frequent watering both in ſummer and winter, but moſt in the ſummer ſeaſon; ſhifting them into larger pots as they encreaſe in growth: obſerving, that although moſt of the ſorts will live in the open air about a month or ſo in the heat of ſummer, it will be beſt to expoſe them but ſparingly, rather place them in an airy glaſs-caſe for a month or two in the ſummer, moving them to the ſtove again in due time.

MIRABILIS, Marvel of Peru, or Four-o'clock-flower.

This genus conſiſts of three large-growing buſhy, very floriferous perennials, from Peru in South America, admirably ornamental for the pleaſure-ground in ſummer, but which, although naturally perennial, often prove annual here: all of them, however, riſing with annual ſtalks, three or four feet high, branching widely all around; cloſely ornamented with large, oblong, entire leaves; and numerous, beautiful, monopetalous, funnel-ſhaped flowers, of beautiful colours.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is pentaphyllous, erect, ventricoſe, the leaves oval and perſiſtent. COROLLA, is monopetalous and funnel-ſhaped, having a long ſlender tube reſting on the nectarium; the limb or upper part erectly ſpreading, plaited, and obtuſely quinquifid, and with a globoſe nectarium under the corolla. STAMINA, five ſlender, unequal, inclinated filaments, and roundiſh antheræ. PISTILLUM, a roundiſh germen within the nectarium, ſlender ſtyle, and globular ſtigma. PERICARPIUM, none, the ſeed is an oval pentagonous nut.

There are but three ſpecies, all of which are natives of Peru, in the Spaniſh Weſt Indies, and in this country are tender, generally requiring to be forwarded in ſpring in a hot-bed until June.

The ſpecies are:

[1]MIRABILIS *Jalapa.*

*Jalap Mirabilis, or Common Marvel of Peru.*] Hath a large, thick, fleſhy root; an upright, thick, jointed ſtalk, dividing and branching numerouſly, widely, and erectly, a yard or more high; garniſhed with oblong, broad, oppoſite leaves; and all the branches and ſhoots terminated by numerous flowers in cluſters, of different colours in the varieties.

*Varieties.*] With white flowers—with yellow flowers—with purple flowers—with red flowers—with white and yellow flowers—white and purple flowers—purple and yellow flowers—red and yellow flowers.

Several other varieties often riſe from ſeed; and it is remarkable that although ſeveral of the above colours and variegations are ſometimes common to the ſame plant, yet it is rare that a plant of this ſpecies produce flowers of one of thoſe colours alone; ſometimes, however, the ſame plant will exhibit only white and purple flowers ſeparate, and ſometimes both colours in the ſame flowers, intermixed with the plain ones; the ſame is alſo obſervable in the red and yellow; others have plain flowers of ſeveral different colours; and ſometimes variegated flowers alſo on the ſame plant.

The root of this ſpecies was ſuppoſed to be the true officinal jalap, but which is ſince diſcovered to be the root of a ſpecies of *Convolvulus.*

[2]MIRABILIS *Longiflora.*

*Long-flowered Mirabilis.*] Hath a large, thick, fleſhy root; a thick ſtalk, dividing low into many declinated ſpreading branches, extending two or three feet every way; large, heart-formed, hairy, viſcous leaves, in oppoſite pairs; and all the branches and ſhoots terminated by white flowers in cluſters, having very long tubes, nodding downward.

[3]MIRABILIS *Dichotoma.*

*Dichotomous, or Forked Mirabilis.*] Hath a thick fleſhy root; an upright, thick, ſwollen, jointed ſtem, branching forkedly, two or three feet high; oblong oppoſite leaves; and ſmalliſh red flowers at the axillas, ſingly and cloſe-ſitting.

All theſe plants flower in July, continuing in plentiful ſucceſſion until October, very conſpicuous and elegant. Having the ſingularity of being ſhut all day, and expand towards the evening when the ſun declines; hence the inhabitants of the Indies, where they grow naturally, called them Four-o'clock-flowers: their time of opening here, however, depends on the weather, for if cloudy, or that the ſun is not very vehement, they often open great part of the day.

The flowers are univerſally hermaphrodite, and of one funnel-ſhaped tubular petal, having the lower part a long narrow tube, and the upper ſpreading. See the *Characters.*

Theſe plants are naturally perennial in root, which, however, if not preſerved here in winter, prove but of one year's duration, but if ſheltered from froſt and wet during the winter ſeaſon, they will remain alive, and

ſhoot

ſhoot out ſtrongly again in ſpring: in this country, however, the plants are commonly conſidered as annuals; becauſe they riſing from ſeed in the ſpring, and the ſame year produce flowers and perfect ſeed; and if left to nature in the open air, totally periſh in winter, at the firſt attack of froſt or exceſſive wet; but, as aforeſaid, if in autumn when the ſtalks begin to aſſume a ſtate of decay, the roots are taken up, and preſerved in ſand in a dry room all winter, and planted again in ſpring, they ſhoot out afreſh ſtronger than at firſt, and ſometimes obtain four or five feet ſtature, with very ſpreading heads; or if plants growing in pots, having the ſtems cut down in autumn, and the pots placed in a green-houſe, or garden-frames under glaſſes, the roots may alſo be preſerved ſound, and will ſhoot out again in ſpring as above.

The roots generally become large, tuberous and fleſhy, covered with a dark rind.

All the ſpecies are of a tender nature, ſcarcely able to endure the open air here fully day and night, until May or June; that is, they being raiſed from ſeed in ſpring, chiefly in hot-beds under glaſſes, continued and forwarded there until the beginning of June, then fully expoſed in the borders or pots, they become large branchy plants in July and Auguſt, and continue flowering until October or November, till prevented by the cold.

They are all elegant furniture for the principal compartments of the pleaſure-ground, they being both very ornamental in their large branchy growth, cloſely garniſhed with leaves, and by flowering ſo numerouſly ſeem as if entirely covered with flowers, in conſtant plentiful ſucceſſion from July till the beginning of winter, as aforeſaid.

The roots of all theſe plants is a ſtrong purgative, and given in a double quantity operate equal to the true jalap.

*Their Propagation and Culture.*

The propagation of all the ſpecies is by ſeed in the ſpring, either in a warm border, or in a hot-bed; but the latter will forward the plants to conſiderably the earlieſt and greateſt degree of perfection.

Firſt, by raiſing them in warm Borders.—Remark, we only recommend this in default of the convenience of hot-beds; and April is the proper ſeaſon for this mode of ſowing theſe ſorts: chuſe a warm ſouth border, open to the ſun; there ſow the ſeed in ſhallow drills, half an inch deep, and ſix inches aſunder: if the place is covered with hand-glaſſes, or with a frame and lights, or any other occaſional ſhelter on nights and cold weather, it will forward the germination of the ſeed, and growth of the young plants: in June they will be fit to tranſplant into the borders or in pots, chuſe moiſt weather, and give water and occaſional ſhade till rooted, they will then readily grow and acquire a tolerable ſize; but theſe will hardly attain a large ſize ſo ſoon, nor flower ſo early by a month or ſix weeks, as thoſe brought forward in a hot-bed.

By Hot-beds.—By ſowing and forwarding in hot-beds, under frames and glaſſes, is the only method by which we can obtain Marvel of Peru in due perfection in the proper ſeaſon: therefore in March prepare a hot-bed under frame and lights, as directed for tender annuals, ſuch as balſamine, &c. and earth it all over about ſix inches deep; ſow the ſeed in the earth of the bed, in ſhallow drills half an inch deep, as aforeſaid, or in pots of rich earth the ſame depth, plunging them in the earth of the bed. The plants will ſoon riſe; indulge them with freſh air daily, in common with other plants of the bed, by tilting the glaſſes, and give frequent refreſhments of water. When they are near two inches high, prick them into another freſh hot-bed to forward them, placing them either in the earth of the bed, four or five inches aſunder, or plant them ſingly in ſmall pots (thirty-twos), and plunge them in the bed: as ſoon as planted give water, and ſhade them from the mid-day ſun occaſionally till freſh-rooted, continuing the care of admitting freſh air every mild day; and towards the middle or latter end of May, when they have acquired ſome ſize and ſtrength, begin to inure them by degrees to the full air, ſo as by the firſt or ſecond week in June they may be removed into it fully, at which time chuſe mild cloudy weather, if ſhowery the better; take up thoſe growing in the bed, with balls of earth about their roots, and plant them in the borders; or if in pots, they may be readily turned out with the whole ball entire, and planted without their ever ſhrinking or feeling their removal; ſome may alſo be planted in large pots to remain in order for moving to ornament any particular compartment: obſerving to give water directly, and beſtow occaſional ſhade to ſuch as ſhall require it, together with a repetition of waterings to the whole, till they have ſtruck freſh root and begin to grow: after this they will not require any farther culture, except occaſional

ſional ſupport of ſtakes, which will be more particularly neceſſary in the *Mirabilis Longiflora*.

They will moſtly begin flowering in July, and will furniſh plenty of ripe ſeed in autumn for the purpoſe of propagation another year.

But as we before ſuggeſted, that if the roots are taken up in autumn, i. e. October, or early in November, dried, cleaned, and laid in dry ſand, in any dry room, ſecure from froſt and wet, they will remain ſound; and in ſpring, if planted in large pots, and in March or April plunged in a hot-bed under a deep frame, they will ſhoot out remarkably ſtrong, ſometimes four or five feet high, flower earlier by a month than ſeedlings of the ſame year.

Or ſuch of the plants as grow in pots, that having their ſtems cut down in October or November, may be placed in their ſaid pots in a green-houſe, near the windows, all winter, kept from wet, the roots will remain ſound, and in ſpring treat them as above.

MOMORDICA, Male Balſam Apple.

The plants are herbaceous trailers, of which there is a hardy perennial, cultivated both for variety and medical uſe, having long trailing ſtalks, garniſhed with broad ſimple leaves, and monopetalous monoecious flowers.

Claſs and order, *Monoecia Syngeneſia*.

*Characters.*] CALIX, male and female flowers apart on the ſame plant, having monophyllous, concave, five-parted cups, and thoſe of the females are placed on the germen. COROLLA, is monopetalous, large, rough, ſpreading, and adheres to the calix. STAMINA, three awl-ſhaped filaments in the males, with eared antheræ, two of them bifid, one ſingle. PISTILLUM, a large germen under the corolla, taper trifid ſtyle, and three oblong gibbous ſtigma. PERICARPIUM, an oblong-oval trilocular fruit, opening with elaſtic force, filled with many compreſſed ſeeds.

There are ſeveral annual ſpecies of but little merit; but the ſort commonly cultivated is the following perennial.

MOMORDICA *Elaterium*.

*Elaterium, or Wild Spurting Cucumbers.*] Hath thick, fleſhy, ſpreading roots; many trailing, angular, rough ſtalks, branchy and ſpreading two or three feet all around; garniſhed with large, angular, heart-formed, rough, grey leaves, on long rough ſoot ſtalks; and at the axillas ſmall, monoecious, yellow flowers; ſucceeded in the females by oval, cucumber-like, hiſpid fruit, that dart out their ſeeds with great velocity.

This ſpecies is one of the *Noli me tangere*, or Touch-me-not kinds, for upon handling the ripe fruit, it inſtantly burſts with elaſtic violence, and diſcharge its juice and ſeeds with amazing force all around to a great diſtance, often cauſing conſternation to ſtrangers who happen to touch them.

This plant is very hardy, and grows freely from ſeed in the common ground, and is of ſeveral years duration.

The fruit affords the officinal elaterium for medicine.

The propagation of this plant is by ſeed in autumn or ſpring, in a bed of common earth, ſowed either by broad-caſt and raked in, or in drills half an inch deep; and when the plants have leaves two inches broad, tranſplant them, thoſe intended for uſe in rows three or four feet aſunder; and may alſo diſperſe ſome in the pleaſure-ground for variety: give occaſional watering till freſh-rooted.

From the ſelf-ſowed or ſcattered ſeeds, many young plants often riſe ſpontaneouſly.

MONADELPHIA, the name of the ſixteenth claſs of the Linnæan ſyſtem, conſiſting of plants with hermaphrodite flowers, having all the ſtamina monadelphous or united into one body, with the ſtyle paſſing through them: examples of monadelphous plants are hollyhock, lavatera, marſh-mallow, &c. and conſiſts of five orders, ariſing from the number of ſtyles (five). See CLASSIS.

MONANDRIA, the name of the firſt claſs in the Linnæan ſyſtem: conſiſting of plants with hermaphrodite flowers, having but one ſtamina. Examples of Monandrous plants are Indian arrow-root, blite, &c. and conſiſts of two orders, derived from the number of ſtyles (two). See CLASSIS.

MONARDA, *(Monarda)* Lion's Tail.

It conſiſts of herbaceous, fibrous-rooted, floriferous perennials and biennials, of upright growth for the pleaſure-ground, riſing with angulated erect ſtems, two or three feet high, adorned with oblong ſimple leaves, and terminated by large heads of monopetalous ringent flowers.

Claſs and order, *Diandria Monogynia*.

*Characters.*] CALIX, is monophyllous, tubulous, cylindric, channelled, five-parted at top, and permanent. COROLLA, is monopetalous, with a cylindric tube, ringent above, divided into two lips, the upper one narrow and entire, and the under broad, reflexed, and three-parted. STAMINA, two briſtly filaments involved in the upper lip, and

and compreſſed erect antheræ. PISTILLUM, a quadrifid germen, filiforme ſtyle, involved with the ſtamina, and acute bifid ſtigma. PERICARPIUM, none, four naked ſeeds lodged in the calix.

There are about three ſpecies cultivated in our gardens; are all North American plants, and hardy enough to ſucceed here in the open ground; proper for ornamenting the pleaſure-garden as flowery plants.

The principal ſpecies are;

[1]MONARDA *Fiſtuloſa.*—(*Perennial*).

*Fiſtulous Canada Monarda.*] Hath a fibrey, ſtrong, ſpreading root; upright, obtuſe-angular, hairy ſtems, riſing a yard high, branching out at top; oblong, broad-baſed, pointed, hairy, oppoſite leaves, on long foot-ſtalks; and all the ſtalks and branches terminated by large heads of fiſtulous purple flowers.

[2]MONARDA *Didyma.*—(*Perennial*).

*Didynamous Penſylvanian Scarlet Monarda, or Oſwego Tea.*] Hath a creeping root; upright, acute-angular ſtems, riſing two feet high; oval-lanceolate, ſmooth, oppoſite leaves, on ſhort foot-ſtalks; and the branches terminated by large heads of bright-red flowers, ſometimes having didynamous ſtamina.

The leaves of this ſpecies are remarkably odoriferous, and in North America are ſometimes uſed for tea.

[3]MONARDA *Punctata.*—(*Biennial*).

*Punctated Virginian Monarda.*] Hath fibrey roots; upright ſquare ſtalks, branching quite from the bottom to top, about two feet high; ſpear-ſhaped, ſerrated leaves, of different ſizes in cluſters at each joint; and large verticillate, yellow flowers, having the corolla punctated or dotted with purple.

All theſe plants flower here abundantly in July, make a very ornamental appearance; ſucceeded by ripe ſeed in autumn, by which all the ſorts may be raiſed; the perennial ſorts alſo by roots and cuttings. See the *Propagation.*

The flowers are univerſally hermaprodite, monopetalous, and ringent, numerous and collected into heads, each having a leafy involucrum.

All the three ſpecies are very hardy, the firſt and ſecond are perennials, the other is biennial, and ſometimes annual, if raiſed early in ſpring. They all ſucceed in any open compartment, and are proper furniture for the embelliſhment of the pleaſure-ground, in the elegance of their flowers, which are very conſpicuous, continuing long in full beauty, and are all fine aromatics.

The propagation of all the ſorts is by ſeed; the perennials alſo by parting the roots, and by ſlips and cuttings.

By Seed.—Sow it in autumn, or early in ſpring, in a bed of good earth, and rake it in: the plants will ſoon riſe, and be fit to prick out in June, in nurſery rows half a foot aſunder, giving water, and let them remain till October or November, then tranſplant them where they are to flower.

By planting the Roots.—Autumn or early in the ſpring is the proper time, when, of the two perennial ſorts, divide or ſlip the roots into ſets; almoſt every bit will readily grow, planting them either in a nurſery for a year, or, if ſtrong, at once where they are to remain, and each will flower next ſummer.

By Slips, &c.—In May or June take off ſome robuſt ſlips or cuttings of the branches, five or ſix inches long, plant them in a ſhady border, giving occaſional waterings, and they will readily grow, and form good plants by autumn.

MONOECIA, the name of the twenty-firſt claſs in the Linnæan ſyſtem, conſiſting of plants with male and female flowers, ſeparated on different parts of the ſame plant. Examples of monoecious plants, are cucumber, melon, gourd, &c. and conſiſts of eleven orders, from the number of ſtyles (eleven). See CLASSIS.

MONOPETALA, Monopetalous, of one petal; applicable to flowers only; and a corolla formed of one leaf, or petal, is termed Monopetalous. A Monopetalous corolla is ſometimes wholly entire, without any diviſion; ſometimes is cut into two parts, *biſidum*; in three, *triſidum*, or *tripartite*; in four, *quadriſidum*; in five, *quinqueſidum*; in many, *multiſidum*, &c. See COROLLA.

MONOPHYLLA, Monophyllous, or one leaved, applicable moſt commonly to the calix of flowers; for a calix of one leaf only, is termed Monophyllous, and which ſometimes conſiſts of one entire piece without diviſions, *integerrimum*; ſometimes cut into two, *biſidum*; ſome into three, *triſidum*; in four, *quadriſidum*; in five, *quinqueſidum*; in many, *multiſidum*, or *multipartite*. See CALIX and PERIANTHIUM.

MORUS, Mulberry-tree.

This genus is wholly of the tree kind, and moſtly deciduous; conſiſting of about ſix or ſeven ſpecies, four of them hardy for the open

ground;

ground; ſome of which as fruit-trees, and ſome for variety; and two are tender exotics, rarely cultivated here: all of them adorned with large, heart-ſhaped, oval, and oblong, rough leaves; and monoecious apetalous flowers, the males in amentums, and the females in round heads, formed of the ſucculent calixes, which become the fruit.

Claſs and order, *Monoecia Tetrandria.*

*Characters.*] CALIX, monoecious flowers, the males collected into amentums, having cups divided into four oval concave parts; and the females into round cluſters, having cups compoſed of four roundiſh, ſucculent, permanent leaves. COROLLA, none. STAMINA, in the males, four ſubulate filaments, and ſimple antheræ. PISTILLUM, in the females a cordate germen, two ſubulate, long, reflexed ſtyles, and ſimple ſtigmas. PERICARPIUM, none, the female calixes become large, fleſhy, ſucculent berries, full of tubercles, each tuberance having an oval acute ſeed.

The moſt remarkable ſpecies of this noted genus are the four following, all of hardy growth; the firſt of which is the common Mulberry of our gardens.

[1]MORUS *Nigra.*

*Common Black-fruited Mulberry-tree.*] Riſes with an upright, large, rough trunk, dividing into a large, branchy, very ſpreading head, riſing twenty feet high or more; large, heart-ſhaped, rough leaves; and monoecious flowers; ſucceeded in the females by large, ſucculent, black berries.

*Variety.*] With jagged leaves and ſmaller fruit.

This ſpecies is the proper Mulberry-tree for general cultivation in this country for its fruit; the tree being a plentiful bearer, and the fruit ripen in good perfection in Auguſt and September.

[2]MORUS *Alba.*

*White Mulberry-tree.*] Riſes with an upright trunk, branching twenty or thirty feet high; garniſhed with large, oblique, heart-ſhaped, ſmooth, light-green, ſhining leaves; and monoecious flowers; ſucceeded by pale-whitiſh fruit.

*Variety.*] With purpliſh fruit.

[3]MORUS *Papyrifera.*

*Paper Mulberry-tree of Japan.*] Grows twenty or thirty feet high; with large palmated leaves, ſome trilobate, others quinquelobed; and monoecious flowers, ſucceeded by ſmall black fruit.

In the countries where this tree grows naturally, the inhabitants make paper of the bark.

[4]MORUS *Rubra.*

*Red Virginia Mulberry.*] Grows thirty feet high; with very large, heart-ſhaped, rough leaves, hairy underneath; and monoecious flowers, ſucceeded by large, reddiſh berries.

All theſe trees are very hardy, ſucceed in any common ſoil and ſituation. The *Morus Nigra*, Black Mulberry, is the only ſort proper to cultivate as a fruit-tree for its fruit, the others are principally employed here to form variety in our ornamental plantations, of which the White and Paper Mulberry, are the moſt common, the red ſort being very ſcarce in the Engliſh gardens; the black, and the white-fruited kinds, are alſo eminent for their leaves to feed ſilk-worms, they being the principal food of theſe valuable inſects; but the White Mulberry leaves are in the moſt eſteem for this purpoſe; and abroad, in France and Italy, &c. vaſt plantations of the trees are made ſolely for their leaves to feed ſilk-worms, which amply reward the poſſeſſors with the annual ſupply of ſilk they ſpin from their bowels: plantations of the ſame trees has formerly been recommended in this country for the purpoſe of ſilk-worms, to introduce the manufacturing of raw ſilk, ſince it is obſervable that where the trees thrive, the ſilk-worms will alſo proſper: all recommendations, however, have proved fruitleſs, although it in time might probably turn to a national advantage.

The leaves of theſe trees are generally late before they begin to come out, the buds ſeldom beginning to open till the middle or towards the latter end of May, according to the temperature of the ſeaſon; and when theſe trees in particular begin to expand their foliage, it is a good ſign of the near approach of fine warm ſettled weather: the white Mulberry, however, is generally forwarder in leafing than the black.

The flowers and fruit come out ſoon after the leaves; the males in amentums, as before hinted, and the females in ſmall roundiſh heads; neither of which are very conſpicuous, nor poſſeſs any beauty, but for obſervation; the female or fruitful flowers always riſe on the extremity of the young ſhoots, on ſhort ſpurs; and with this ſingularity, the calixes of the flowers become the fruit, which is of the berry kind, and being compoſed of many

tuberances, each of theſe furniſh one ſeed. See *Characters*. The fruit ripens here gradually from about the middle of Auguſt until the middle of September; which in dry warm ſeaſons ripen in great perfection, but when it proves very wet weather, they ripen but indifferently, and prove devoid of flavour.

Conſidered as fruit trees, the black-fruited kind is the only proper ſort to cultivate, the trees being not only the moſt plentiful bearers in this country, as before noticed, but the fruit are larger, and much finer flavoured than the white kind, which is the only ſort, beſides the Black Mulberry, that bear fruit in England.

The Black Mulberry, therefore, as a fruit-tree, may be trained either as a ſtandard, half-ſtandard, dwarf-ſtandard, and as wall-trees and eſpaliers. Standards is the moſt common mode of cultivating them, in gardens and orchards, and in which they bear very abundantly; but in large gardens, where there is ſcope to work upon, a few trees may be alſo trained in each of the other above methods: they will effect the greater variety; and thoſe againſt walls and eſpaliers will generally have larger fruit, ripen ſooner with an improved flavour; and which will be ſucceeded by thoſe upon the ſtandards: remark, however, to allot a ſufficiency of ſtandards to furniſh the principal crop of fruit, which, if for private uſe, half a dozen trees may be ſufficient, though I have known one large tree furniſh more Mulberries than was neceſſary for the ſupply of a great family.

The trees may be planted either in the kitchen-garden, orchard, or pleaſure-ground, allowing them a dry ſituation and ſunny expoſure, both of which being requiſite to promote the early ripening of the fruit, and give it due flavour; ſtandard Mulberries are often diſpoſed ſingly on graſs ground, in which when grown up into ſpreading heads, they have a fine effect, and their fruit may be always readily gathered; though when growing on cultivated ground, it is probable the fruit may be larger: the ſtandards ſhould ſtand twenty or thirty feet aſunder at leaſt, to give full ſcope to their ſpreading heads; and the dwarfs, for walls and eſpaliers, fifteen or twenty feet diſtance from one another; remarking, that in all the above modes of training, not to practiſe any general ſhortening of the ſhoots, but, except on particular occaſions, leave them moſtly at full length; for as the fruit is produced near the ends of the young wood, ſhortening would be cutting off the parts deſigned by nature to yield the fruit. See their *Propagation*, &c.

Mulberry-trees rarely bear any conſiderable quantity of fruit till they are many years old; and old trees are always not only the moſt fruitful, but the fruit larger and of a richer flavour.

Ripe Mulberries are an agreeable ſweet fruit, of a refreſhing reliſh, and fine cooling quality, and therefore excellent for the deſert; alſo proper for ſome culinary uſes, as for tarts, &c. and the ſyrup of Mulberries is well known.

The bark of the root of theſe trees being a fine bitter aſtringent, is admirable for killing worms in the human body.

*Propagation of all the Sorts.*

The propagation of all the ſorts is by ſeed, by layers, and by cuttings; alſo by graſting and inoculation.

By Seed.—All the ſorts may be raiſed in amazing plenty from ſeeds in the open ground, but remarking that when they are deſigned principally as fruit-trees, I would not recommend this practice, becauſe the ſeedling-trees are apt to vary, and out of numbers ſo raiſed, there may be but few good ſorts, or that prove good bearers; therefore for fruit-trees, layers, cuttings, grafting, &c. are the only certain methods to continue the approved ſorts. By ſeed, however, is eligible enough where large quantities are required for barren plantations, or for ſhrubberies, &c. it is generally procured from France or Italy; and March is the proper time of the year of ſowing them, which may be either in a warm border, or in a moderate hot-bed, earthed half a foot deep, and arched with hoops to be matted in nights and cold weather. Sow the ſeeds in ſhallow drills near half an inch deep: give refreſhments of water occaſionally, and when the plants appear, mat them in cold nights and morning froſts, repeating the waterings all ſummer in dry weather; and in winter continue the occaſional ſhelter of mats when froſts approach. And after having two years growth in the ſeed-bed, plant them out in nurſery-rows two feet aſunder, and half a yard apart in the lines: here let them remain a few years, training them for their ſeveral purpoſes, as above mentioned, the principal part for ſtandards, with ſingle ſtems, ſix feet high; others for half-ſtandards; and a few for dwarfs, heading down

the dwarfs, while young, near the ground, to force out branches near the bottom, to train either for dwarf-ſtandards, or for walls or eſpaliers.

But the following are the only methods of propagation by which we can with certainty continue the approved ſorts; in all of which methods always, if poſſible, propagate from trees remarkable for bearing large fruit, and plentiful crops.

By Layers.—Where great quantities are required, ſome trees ſhould be planted for ſtools, having the heads taken off near the ground to force out plenty of bottom-ſhoots near the earth for laying; for the branches of the full-grown trees are often ſo far from the ground, that they cannot be brought down low enough to be layed; in this caſe, however, where only a few are wanted, ſome large pots, boxes, or baſkets of mould may be elevated upon ſtands near the branches proper for laying. In either method lay the ſhoots by ſlit-laying, heading them to one eye above the ſurface; thus they will readily take good root, ſufficient for tranſplanting by autumn following, in nurſery-rows: as for the ſeedlings, train them in the ſame manner.

By Cuttings.—October and November is the proper ſeaſon; chuſe young ſhoots of the former ſummer, from healthful good-bearing trees, cutting them off from about eight or ten to fifteen inches long, plant them in a ſhady well-ſheltered place, in rows, ſetting them two thirds at leaſt in the ground; many of them will be properly rooted next autumn. But the moſt expeditious method is to give them the aid of a hot-bed; in March, therefore, plant a parcel of middling cuttings in pots of earth, and plunge them in any moderate hot-bed, it will greatly facilitate their rooting; being careful to harden them by degrees to the full air; give occaſional ſhelter in the following winter, and in ſpring plant them out in the nurſery-way, treating them as above directed.

By Graſting and Budding.—This is rarely practiſed, ſince they grow ſo freely by layers and cuttings; graſting and budding, however, are alſo certain methods for continuing the proper ſorts; and when intended for practice, it muſt be performed on ſeedlings of any of the ſpecies, in the uſual method.

*Culture as Fruit-trees.*

As before obſerved, they as fruit-trees may be trained both as ſtandards in the open-ground, and as dwarfs for walls and eſpaliers.

As Standards.—They may be both full ſtandards, half-ſtandards, and dwarf-ſtandards, but principally as full or half-ſtandards. To have them full-ſtandards, train them with a ſingle, upright, clean ſtem, ſix feet high at leaſt, then top them to branch out laterally at that height to form a head. Half ſtandards train with fouror five feet ſtems, then let them branch into heads. Dwarf-ſtandards may have half a yard or two-feet ſtems, at which height encourage branches all around for a head, (ſee STANDARD-TREES, DWARF-TREES, &c.) obſerving to aſſiſt the whole a little at firſt, when neceſſary, in forming their heads ſomewhat regular, by pruning irregular growths, as directed for other ſtandard and dwarf fruit-trees. In either of theſe forms they may be planted out in the garden or orchard; where let them principally take their own natural growth, giving no other pruning than regulating or retrenching any croſs-diſpoſed, or other irregular branches, or thinning where much too cloſe. Never ſhorten the ſhoots, unleſs their ends are dead; for the fruit-ſpurs always ariſe towards the extreme part of the young wood, as already obſerved.

Thus will all theſe kinds of ſtandard Mulberries gradually form themſelves into a bearing ſtate, though they rarely begin to bear any great quantity till twelve or fifteen years old.

As Dwarfs for Walls, &c.——Although the fruit ripen very well upon ſtandards, yet when trained againſt walls and eſpaliers, the ſize and flavour is often conſiderably improved; therefore it is proper to have a few trees trained in both theſe ways, i e. walls and eſpaliers, for variety: one mode of culture often ſerves both. They are at firſt to be headed down low in the nurſery, to procure branches near the ground, as directed under the article DWARF-TREES, &c. then, being thus furniſhed with ſome lower branches, plant them againſt a ſouth-wall, or in eſpaliers, fifteen feet aſunder; where train their branches along horizontally, regularly to the right and left, ſix inches aſunder, each at full length, for the reaſon already given, unleſs where ſhortening is neceſſary to obtain a ſupply of wood to fill the allotted ſpace; which ſhould be regularly covered with bearing-branches quite from bottom to top of the wall or eſpalier, at the above diſtance from one another; obſerving each year in ſummer and winter pruning, to cut out all ſuperfluous and irregular ſhoots; at the ſame time train in different

rent places of each tree ſome regular lateral ſhoots, both towards the lower and upper parts, to be coming forward to a bearing ſtate, that every part of the tree may be filled with bearing ſhoots, advancing one after another, and as the foremoſt ſhoots become too long, and require cutting off, the laterals will one after another, as juſt obſerved, be ready to ſupply their places; and likewiſe of ſuch parts as become cankered or dead.

When theſe trees are required for plantations for variety, they ſhould be trained up either to full ſtems, ſix feet high at leaſt, and then ſuffered to branch out in their natural way, or may be trained as half-ſtandards for ſmaller ſhrubberies, or even ſome as dwarfs, to cauſe a greater variety.

MOTUS, Motion. The term Motion, applied to plants, is expreſſive of the direction of growth in different parts of plants.

The direction of the Motion of the roots and ſtems is totally oppoſite; the former either running directly downward into the ground, or horizontally under the ſurface; and the ſtems direct their Motion towards the air and light of the ſun, moſtly in an upright poſition; but many run horizontally along the ſurface of the earth.

The cauſes which concur in promoting the Motions of plants, are the moiſt and warm vapours of the earth to the root, and the air and light of the ſun to the ſtem; for place any number of plants growing in pots, in a room which only admits a ſmall portion of light at one place, the ſtems will all incline towards that ſide; in cloſe dark thickets the young trees always lean to the part where the moſt light penetrates; and the new ſhoots of an eſpalier, or wall-tree, detach themſelves from the eſpalier or wall, in queſt of the free air and light.

The force of Motion ſeems to be greater in roots than in ſtems; the root without ever once going out of its way pierces the hardeſt ſoils, penetrates into walls, which it overturns, and even into rocks, which it ſplits; whereas ſtems and branches ſurmount an obſtacle, by leaving their natural direction, and over-topping it.

Although the natural direction of moſt ſtems or trunks be to aſcend, as was before obſerved, yet ſome by their weakneſs, or natural tendency deſcend, and ſometimes by means of roots breaking out all along the ſtems and branches, as in ſtrawberry, penny-royal, and many other repent plants, ſuch ſtems are by theſe roots ſtriking into the earth, tethered as it were to the ground, and only their extremities can direct their courſe upwards.

Leaves and flowers alſo direct their courſe towards the air, and light of the ſun; leaves always turn their upper ſurface outward to the air and light; very obvious in wall-trees, and that if a branch is over-turned, ſo that the leaves are turned the contrary way; they will all naturally direct their ſurfaces again gradually upward to the light and air, tho' this often coſts them ſeveral days growth: many flowers alſo preſent their ſurface directly to the ſun, and follow the diurnal courſe of that luminous body, ſuch as the ſun-flower, and moſt of the compound flowers; in all of which the diſk or ſurface looks towards the eaſt in the morning, the ſouth at noon, and the weſt at night.

During the heat of the ſun the pinnated or winged leaves, particularly of the papilionaceous tribe, riſe vertically upward; the oppoſite lobes or folioles, which compoſe theſe leaves, riſe ſo as they are generally applied cloſe together by their upper ſurfaces; but in that ſtate of the atmoſphere which generally precedes a ſtorm, or during a cloſe moiſt cloudy air, the lobes of the ſame ſort of leaves extend themſelves commonly along the foot-ſtalk; and after ſun-ſet they incline ſtill lower, and hang vertically down under the foot-ſtalk, and are applied cloſe together like the leaves of a book, by their lower ſurfaces; this Linnæas calls the ſleep of plants.

Many ſimple leaves, when the ſurface is expoſed to an ardent ſun, become concave above, but gradually recover as the heat declines.

But of all the Motions of leaves, none is ſo ſudden and rapid as that of the ſenſitive and humble plants. See MIMOSA.

Another kind of Motion in plants is elaſticity, which is reſident particularly in ſome ſorts of ſeed-veſſels, ſuch as the yellow balſamine, and ſpurting cucumber, &c. in which their fruit, when arrived at maturity, burſt open like a ſpring, and dart out their ſeeds alſo with elaſtic force to a conſiderable diſtance.

MOULD, or Earth. See EARTH.

MULCH, a ſort of ſtrawey dung, ſomewhat moiſt, and not rotted, and is uſeful in gardening, to protect the roots of new-planted choice trees or ſhrubs from ſevere froſt in winter; and from being dried by the fierce ſun or

drying winds in ſpring and ſummer, before they are well rooted; for both of which purpoſes, it is ſpread evenly on the ſurface of the ground round the ſtem of the tree, as far as the roots extend, about three or four inches thick; but which may be augmented in winter if the ſeverity of the froſt render it neceſſary.

MULTICAPSULARE, Multicapſular, or many capſules; plants whoſe ſeed-veſſel is formed of ſeveral capſules united in one as it were, ſuch as thoſe of columbine, peony, aconite, larkſpur, and the like. See CAPSULA.

MULTIFIDUS, Multifid, many parts, a flower, or calix of a flower that is divided into many ſegments; the term is alſo applicable to leaves. See FOLIA.

MULTIFLOROUS, many flowers on one foot-ſtalk; or,

MULTIPLICATUS *Flos*, a Multiplied Flower; one whoſe petals are multiplied in number beyond their natural, or characteriſtic, or ſingle ſtate, in two, three, or more ſeries; and ſuch kinds are commonly called double flowers.

All Multiplied Flowers, however, are unnatural productions, becauſe the ſingles of every genus are the original, and the doubles are accidentally produced from the ſeeds of the ſingles; for a corolla in its ſingle ſtate, whether of one or ſeveral petals, is that proper from which to draw the characters of any genus; never from doubles, which being only varieties, are not to be depended on; ſo that among botaniſts, double flowers are often termed vegetable monſters, and are diſregarded,; but, on the other hand, double flowers are often the floriſt's pride.

But a double flower is properly that whoſe petal or petals are twice repeated, though in the common acceptation of the word *double*, all flowers whether the petals are twice, thrice, or many times repeated in ſeveral ſeries, are among floriſts generally called by the general name of double flowers; in ſome the petals are often ſo multiplied as to obliterate the parts of fructification, in which ſtate they come under the denomination of luxuriant. See LUXURIANT FLOWERS.

Multiplication is leſs common in flowers naturally of one petal, than thoſe with ſeveral; in the former, however, it frequently happens, as in *campanula*, &c. though not full in the higheſt luxuriance; but in the latter are ſubject to all degrees of luxuriance from the loweſt to the higheſt, exemplified in *anemone*, *ranunculus*, *marſh-marigold*, &c. See PLENUS *Flos*.

MUSA, Plantain-tree, or *Banana*.

It conſiſts of very tall-growing herbaceous perennials of the Indies, for the hot-houſe collection, riſing each with an upright, tapering, ſoft ſtem, fifteen or twenty feet high; adorned at top all around with enormous leaves, two or three yards long, and proportionably broad; and from their centre a large fungus flower-ſtalk; terminated by a vaſt nodding ſpadix of monopetalous, ringent flowers; protruded from the ſpatha; ſucceeded by a great cluſter of cucumber-ſhaped fruit, a ſingle cluſter weighing ſometimes forty or fifty pounds; are eſculent and of a delicious flavour.

Claſs and order, *Polygamia Monoecia*.

*Characters.*] CALIX, male, female, and hermaphrodite flowers on the ſame ſpadix, having female-hermaphrodites on the lower part, and male-hermaphrodites above, all in cluſters, each bunch having a ſpatha for a cup, which is deciduous. COROLLA, each floret of the ſpadix is ringent, forming an upper lip, and a nectarium the lower lip. STAMINA, in the females ſix ſubulate filaments, five of them in the corolla, the other in the nectarium, and is double the length of the others, and terminated by a linear antheræ, the reſt have none; but in the males are equal in the length, and have all antheræ. PISTILLUM, a large, long, triquetrous germen below the receptacle, a cylindric erect ſtyle, and capitated roundiſh ſtigma, but no ſtigma in the males. PERICARPIUM, in the females a very long, fleſhy, obſoletely-triquetrous, trilocular, baccaceous fruit.

The plants of this genus having ſtems ſo ſoft and porous as not to deſerve the name of trees, only in ſtature, eſpecially as they are perennial only in root, the ſtems dying down to the ground annually in their native ſoil, after having borne their crop of fruit; they are naturally ſo quick in growth, as to ſhoot from the bottom to fifteen or twenty feet height, flower, and produce ripe fruit, all in the ſpace of nine or ten months: the ſtem is about half a foot thick, and of ſo ſoft a nature, as it may be eaſily cut down at one ſtroke.

The ſpecies are;

1 MUSA *Paradiſiaca*.

*Tree of Paradiſe, or Common Plantain-tree.*] Hath a ſtrong, fibrey, very ſpreading root; an herbaceous, upright, taper ſtem, riſing fifteen or twenty feet high; terminated by a cluſter of very large leaves, about two yards long, and half a one broad; and a large,

long, nodding ſpadix of whitiſh-yellow, polygamous flowers, having the males perſiſtent; ſucceeded in the others by an exceeding large cluſter of long, narrow, yellowiſh, delicious fruit.

Some authors have ſuppoſed this tree, from the prodigious ſize of its leaves, to be that whoſe leaves our firſt parents uſed for cloathing in paradiſe; and alſo that the fruit is the forbidden apple which Eve gave to Adam: the ſacred text, indeed, calls the leaves employed for this purpoſe, fig leaves; but the fruit of this is alſo often by the moſt antient authors called a fig, its nature and taſte alſo reſembles that fruit; and its leaves, by reaſon of their great ſize and ſolidity, were much more proper for a veil or covering than thoſe of any ſpecies of *ficus*, which being ſeldom more than eight or ten inches long, and five or ſix broad, whereas thoſe of the ſpecies of this genus, *Muſa*, are two or three yards long with proportionable breadth, could not fail of being pitched upon in preference to all others, eſpecially as they might be eaſily ſewed together with the numerous thread-like filaments, that may with the utmoſt facility be peeled from the ſtem of the tree.

[2]MUSA *Sapientium.*

*Sapient, Spotted Muſa, or Banana-tree.*] Riſes with an upright, herbaceous, ſpotted ſtem, twelve or fifteen feet high; terminated by a cluſter of leaves near two yards long, and half a one broad; a large nodding ſpadix of flowers, having the males deciduous; and large cluſters of ſhort, oblong, very luſcious fruit.

[3]MUSA *Bihai.*

*Bihai, or Broad-leaved Muſa.*] Riſes with an upright ſoft ſtem, fifteen or twenty feet high; with leaves near three yards long, and one broad; and an erect ſpadix of flowers, having a perſiſtent ſpatha; ſucceeded by large cluſters of fruit.

Theſe curious exotics thrive freely here in our ſtoves, flower and produce their enormous bunches of fruit in tolerable perfection; but as the plants grow very tall, and the leaves ſo exceeding large, they require very capacious ſtove-room, both in width and height: they muſt be potted in large pots of rich mould, and plunged conſtantly in the bark-bed, watering them plentifully in ſummer three or four times a week, and about twice in winter.

Their propagation is by ſuckers ariſing from the root, particularly after having fruited, which may be taken off at any time in ſummer, with fibres to their bottom, planted in pots, and plunged in the bark-bed, and they will readily grow; obſerving according as their roots advance in growth to ſhift them into larger pots.

MUSCI, Moſſes, a tribe or family of imperfect plants, which conſtitute the ſecond order of the twenty-fourth claſs, *Cryptogamia*. See CLASSIS.

The plants of this order are for the moſt part ſo exceedingly minute, that their fructification are either entirely concealed, or, from their minuteneſs, or ſituation, are imperfectly viſible. There are of this order not leſs than eleven genera, each of which comprehending many ſpecies, and are moſtly very diminutive and creeping; with exceedingly weak ſtems, creeping and rooting as they extend, cloſely ſet with ſmall cloſe-ſitting leaves; and extend themſelves in a tufted manner, forming a ſort of carpet on the ground, trees, and ſtones; the ſmalleſt ſeldom exceed the third of an inch in height, and the largeſt not above five or ſix; moſtly perennial and evergreen, delight chiefly in moiſt ſhady ſituations, and are remarkably ſlow of growth; the flowers ſo very ſmall that their fructifications have not by the fineſt glaſſes been yet perfectly diſcovered, ſo as to diſtinguiſh their ſex; though ſuppoſed to be univerſally male and female diſtinct; ſometimes they ſit cloſe to the branches, and ſometimes elevated upon long ſlender foot-ſtalks, and are ſucceeded by ſeed, by which they propagate themſelves.

Though from the exceeding minuteneſs of theſe plants, it was formerly ſuppoſed they were only excreſcences produced from the earth, trees, &c. but are no leſs proper plants than thoſe of greater magnitude, though imperfectly viſible in ſome of their eſſential parts; for many inſects are ſo ſmall that they are hardly viſible, much leſs ſo muſt be their eyes, mouth, &c. yet they poſſeſs all the perfect parts of life; ſo it is of the order of plants under conſideration, being poſſeſſed of proper flowers and ſeed.

The ſuppoſed male flowers conſiſt entirely of the antheræ and their covering; a ſort of very ſmall cawl-ſhaped *calyptra*, ſuſpended over the tops of the ſtamina, like an extinguiſher.

The ſuppoſed female flowers are generally formed into a vaſtly ſmall cone, compoſed of numerous ſcales, each ſaid to contain in its wing a ſingle ſeed, as fine as the ſmalleſt duſt.

None

None of theſe plants are ever cultivated, ſo only mention them for their ſingularity, and as conſtituting the ſecond order of the remarkable claſs *Cryptogamia*.

Some of the Moſſes grow in great plenty upon trees, particularly fruit-trees growing cloſe in orchards, eſpecially on cold, moiſt, barren ſoils, and frequently prove very injurious to ſuch trees: the only remedy is to cut down ſome of the trees to admit the ſun and air, and then thin the branches of the remainder; and in winter with an inſtrument of iron hollowed on the edge to fit the branches, ſcrape off the rougheſt of the Moſs, and by two or three repetitions it will be deſtroyed, but more effectually if the ground between the trees is alſo ploughed or digged a due depth, to give vigour to the roots, that the trees may aſſume a free growth at top.

Moſt of the plants of this numerous tribe have the ſingular property, after being preſerved dry ſeveral years, that being moiſtened they will reſume their original verdure.

Some of theſe plants have a wonderful efficacy in preſerving dry ſuch bodies as are ſuſceptible of moiſture, and retaining for a long time the humidity of young plants out of ground; for which reaſon tender young plants or cuttings, &c. as are to be ſent to any diſtance, if wrapped up in ſome ſorts of moſs, it will greatly preſerve their vegetative faculty.

MYRICA, Candleberry Myrtle.

The plants are of the ſhrub kind, conſiſting of hardy deciduous ſhrubs for the pleaſure-garden, and ever-greens for the greenhouſe; all of which riſing with ſhrubby, branching ſtems, from about three to five feet high; garniſhed with oblong, ſimple, entire leaves; and dioecious, apetalous flowers in amentums; ſucceeded by cluſters of ſmall berries; which of ſome of the ſpecies affords a ſort of green wax, with which candles are made; hence the name of Candleberry Myrtle.

Claſs and order, *Dioecia Tetandria*.

*Characters.*] CALIX, male and female flowers on ſeparate plants, in oblong, oval amentums, imbricated on all ſides, formed of many ſmall, concave, moon-ſhaped ſcales, ſerving as calixes, each containing one flower. COROLLA, no petals. STAMINA, in the males four, and ſometimes ſix filaments, and great didymous antheræ, with the lobes bifid. PISTILLUM, in the females an oval germen, two ſtyles, and ſimple ſtigmas. PERICARPIUM, an unilocular berry, having one ſeed.

There are four ſpecies in the Engliſh gardens, two of them hardy and deciduous, and the others tender and ever-green.

*Hardy Deciduous Kinds.*

[1]MYRICA *Cerifera*.

*Ceriferous, or Wax-bearing Myrica, commonly called Candleberry Myrtle.*] Hath an upright ſhrubby ſtem, branching five or ſix feet high, with yellowiſh-brown branches; lanceolate, ſlighly-ſerrated, ſhining green leaves, three inches long, and one broad, placed irregularly on very ſhort foot ſtalks; and dioecious, amentaceous, ſmall, whitiſh flowers at the ſides of the branches; ſucceeded in the female plants by cluſters of ſmall blue berries, replete with a ſort of green waxy matter.

*Variety.*] Dwarf Carolina Candleberry Myrtle with broad leaves.

They are natives of North America, but have been long reſidents of our gardens, and both the varieties are choice furniture for the ſhrubbery; whilſt young they often retain their leaves like an ever-green great part of winter; but when older they conſtantly ſhed their leaves in autumn: the leaves of both ſorts poſſeſs a very agreeable fragrance of an aromatic nature, like a Myrtle.

It is from this ſpecies the North Americans procure the wax for candles, before mentioned.

[2]MYRICA *Gale*.

*Gale, Sweet Willow, or Dutch Myrtle.*] Hath under-ſhrubby, upright ſtems, branching three or four feet high; lanceolate, ſlightly-ſerrated leaves, an inch and a half long, on very ſhort foot-ſtalks; and dioecious, amentaceous, ſmall, whitiſh flowers; ſucceeded in the female plants by cluſters of ſmall berries.

This grows naturally on ſome boggy grounds both in England and other nothern parts of Europe: it is cultivated as furniture for the ſhrubbery, but muſt have a moiſt ſituation.

*Ever-green Kinds for the Green-houſe.*

[3]MYRICA *Quercifolia*.

*Oak-leaved African Myrica.*] Hath a ſhrubby ſtem, branching three or four feet high; oblong, oppoſitely-ſinuated, cloſe-ſitting, ſmooth leaves,

leaves, an inch and a half long, and half as broad; and whitiſh-green flowers, in oval amentums; ſucceeded by ſmall round berries.

*Variety.*] With hairy leaves.

4 MYRICA *Cordifolia.*

*Heart-leaved Æthiopian Myrica.*] Hath a ſhrubby, ſlender ſtem, branching four or five feet high; heart-ſhaped, ſerrated, cloſe-ſitting leaves; and roundiſh amentums of flowers; ſucceeded in the female plants by ſmall berries.

All theſe ſhrubs flower in June and July, which in the firſt and ſecond ſorts are ſucceeded by berries in our gardens; but in the others rarely any in England; neither flowers nor fruit are ornamental; ſo that the merit of the ſhrubs conſiſts in the variety and aromatic fragrance of their leaves, and for which they demand admittance in every good collection; and are all kept in the nurſeries for ſale.

The flowers conſiſt of oblong-oval amentums of many apetalous florets. See the *Characters.*

### *Their Propagation.*

Their propagation is by ſeed, layers, and ſuckers.

By Seed.—The ſeed are procured from the places where the reſpective ſpecies grow naturally. Sow them as ſoon as they can be procured, in boxes of rich earth, half an inch deep, and at the approach of hot weather move them to ſhade, to remain all ſummer, they ſometimes come up the ſame year, if ſowed early, otherwiſe often not till the ſecond; however in winter remove the hardy kinds under a warm hedge, and the others in garden-frames to have ſhelter of the glaſſes in bad weather, and they will all come up the ſecond ſpring; giving water all ſummer, ſhelter again in winter, and in ſpring plant them out, the hardy ſorts in nurſery rows to remain two or three years till proper for the ſhrubbery; and plant the tender ſorts in pots, to be placed among the green-houſe plants.

By Layers.—Chuſe for this operation the young wood, which lay by ſlit-laying in autumn; and during the following ſummer water them plentifully in dry weather, and they will be tolerably rooted by the autumn following; but if not, let them remain another year, to effect it properly; then tranſplant the hardy ſorts in nurſery-rows, to remain till fit for the ſhrubbery; and the tender kinds plant in pots to manage as green-houſe plants.

By Suckers.—The hardy ſorts ſometimes ſend up a few ſuckers, which in autumn may be taken up with roots, and planted out in the nurſery for a year or two.

Cuttings of all the ſorts may alſo be tried, though not to be depended on: chuſe the quite young ſhoots, and if ſome are planted in pots plunged in a hot-bed and covered cloſe with a hand-glaſs, ſome of them may probably take root.

MYRTUS, Myrtle-tree.

This celebrated plant of antiquity compriſes many elegant varieties of the ſhrub kind, for our green-houſe collections, and ſome beautiful ſpecies for the hot houſe, all delightful ever-greens of great fragrance; riſing with branchy ſtems eight or ten feet high, or more, in their native ſoil; cloſely garniſhed with ſimple entire leaves, and quinquepetalous, hermaphrodite flowers from the ſides of the branches, ſucceeded by oval berries.

Claſs and order, *Icoſandria Monogynia.*

*Characters.*] CALIX, is monophyllous, five-parted, placed on the germen, and permanent. COROLLA, is quinquepetalous, the petals oval, and inſerted into the calix. STAMINA, twenty or more capillary filaments inſerted into the calix, and very ſmall antheræ. PISTILLUM, a germen under the corolla, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, an oval umbilicated trilocular berry, each cell having one kidney-ſhaped ſeed.

To this genus Linnæus adds the *Pimento*, or all-ſpice, a beautiful ever-green aromatic, and hot-houſe plant.

There are about four ſpecies of this genus retained in the Engliſh gardens; one is the common Myrtle, a very comprehenſive ſpecies, being the parent of all thoſe different varieties of Myrtle found in our green-houſe collections: the other three ſpecies are for the ſtove.

### *Green-houſe Kind.*

One ſpecies only is for the green-houſe, the common Myrtle, but which, as before obſerved, affords many varieties.

The ſpecies are;

1 MYRTUS *Communis.*

*Common Myrtle-tree.*] Riſes with a ſhrubby, upright, firm ſtem, branching numerouſly all around into a cloſe full head, riſing eight or ten feet high; very cloſely garniſhed with

with oval-lanceolate, entire, moſtly oppoſite leaves, from half an inch to an inch and a half long, and one broad, on ſhort foot-ſtalks; and numerous, ſmall, pale flowers from the axillas, ſingly on each foot-ſtalk, having diphyllous involucrums; each flower ſucceeded by a ſmall, oval, dark-purple berry.

The botanic deſcription is, Myrtus with ſolitary, or ſingly-placed flowers, having a diphyllous involucrum.

The moſt material varieties are;

*Broad-leaved Roman Myrtle.*—Hath oval, ſhining, green leaves, an inch and a half long and one broad, and is remarkably floriferous.

Gold-ſtriped broad-leaved Roman Myrtle.

*Broad-leaved Dutch Myrtle.*—Hath ſpear-ſhaped, ſharp-pointed, dark-green leaves, an inch long, and about three quarters of one broad.

Double-flowered Dutch Myrtle.

*Broad-leaved Jews Myrtle.*——Having the leaves placed by threes at each joint; by which particular circumſtance this ſpecies is in univerſal eſtimation among the Jews in their religious ceremonies, particularly in decorating their tabernacles, and for which purpoſe many gardeners about London cultivate this variety with particular care, to ſell to the above people, who are often obliged to purchaſe it at the rate of ſix-pence or a ſhilling for a ſmall branch; for the true ſort having the leaves exactly by threes, is very ſcarce, and is a curioſity; but by care in its propagation, taking only the perfectly ternate-leaved ſhoots for cuttings, it may be encreaſed faſt enough, and is worth the attention of the curious, and particularly thoſe who raiſe Myrtles for the London markets.

*Orange-leaved Spaniſh Myrtle.*—Has oval, ſpear-ſhaped leaves, an inch and a half long or more, and one broad, in cluſters round the branches, and reſemble the ſhape and colour of orange-tree leaves.

Gold ſtriped-leaved orange Myrtle.

*Common Upright Italian Myrtle.*—Hath its branches and leaves growing more erect, the leaves oval, lanceolate-ſhaped, acute-pointed, and near an inch long, and half a one broad.

Silver-ſtriped upright Italian Myrtle.

White-berried upright Italian Myrtle.

*Portugal Acute-leaved Myrtle.*—Has ſpear-ſhaped, oval, acute-pointed leaves, about an inch long.

*Box-leaved Myrtle.*—Hath weak branches, ſmall, oval, obtuſe, lucid-green, cloſely-placed leaves.

Striped box-leaved Myrtle.

*Roſemary-leaved Myrtle.*——Hath erect branches, ſmall, narrow, lanceolate, acute-pointed, ſhining, green, very fragrant leaves.

Silver-ſtriped roſemary-leaved Myrtle.

*Thyme-leaved Myrtle.*——Hath very ſmall cloſely-placed leaves.

*Nutmeg Myrtle*—Hath erect branches and leaves; the leaves oval, acute-pointed, and finely-ſcented like a nutmeg.

*Broad-leaved Nutmeg Myrtle.*—Silver-ſtriped-leaved.

*Criſtated, or Cock's-comb Myrtle, frequently called Bird's-neſt Myrtle.*—Hath narrow, ſharp-pointed leaves, criſtated at intervals.

Theſe are the principal varieties of the *Myrtus Communis*; but of which ſorts there are ſeveral intermediate varieties of leſs note; and more may ſtill be obtained from ſeed, though the plants are rarely raiſed from ſeed in England, but moſtly by ſlips and cuttings.

They are all beautiful ever-green ſhrubs of exceeding fragrance; exotics originally of the ſouthern parts of Europe, and of Aſia and Africa, and conſequently in this country require ſhelter of a green-houſe in winter: all of which, though rather of the ſmall-leaved kind, have their foliage cloſely placed, and remain all the year, and are very floriferous in ſummer; and when there is a collection of the different ſorts, they afford an agreeable ſource of variety with each other; they therefore claim univerſal eſteem as principal green-houſe plants, eſpecially as they are all ſo eaſily raiſed from cuttings, and of ſuch eaſy culture, as to be attainable in every garden, where there is any ſort of green-houſe, or garden-frames furniſhed with glaſſes for protecting them in winter from froſt: but ſome of the broad-leaved ſorts are ſo hardy as to ſucceed in the full ground, againſt a ſouth-wall and other warm expoſures all the year, by only allowing them ſhelter of mats occaſionally in ſevere froſty weather: ſo that a few of theſe ſorts may be alſo exhibited in a warm ſituation in the ſhrubbery: obſerving, however, all the ſorts are principally to be conſidered as green-houſe plants, and a due portion of them muſt always remain in pots to move to that department in winter. See their *Propagation and General Culture.*

*Stove Kinds.*

There are ſeveral ſpecies of the ſtove temperature, as being natives of the Indies; but there

there are not more than the four following ſorts commonly met with in the Engliſh gardens, all of which are beautiful ever-greens, with larger leaves than the *Myrtis Communis*, and are moſtly ſtrong aromatics.

[2]MYRTUS *Zelanica.*

*Ceylon White-berried Myrtle.*] Hath a ſhrubby upright ſtem, branching erectly ſix or eight feet high; oval, ſhining-green, oppoſite, very odoriferous leaves, on ſhort foot-ſtalks; and all the branches terminated by pedunculi, each ſuſtaining many flowers; ſucceeded by ſnowey-white berries, but rarely in England.

[3]MYRTUS *Pimenta.*

*Pimento, or Jamaica All-ſpice-tree.*] Riſes with an upright tree-ſtem, branching regularly, twenty or thirty feet high, having a ſmooth brown bark; large, oblong-oval, ſtiff, ſhining, very odoriferous leaves, like thoſe of bay, placed alternate; and at the ſides and termination of the branches large looſe bunches of greeniſh flowers; ſucceeded by round, duſky, hard, ſpicey fruit, called all-ſpice, or Jamaica pepper.

This ſpecies is wholly an admirable fine aromatic, its leaves are remarkably fine ſcented; and its fruit is that valuable ſpice, Jamaica pepper, or all-ſpice, ſo called becauſe it is ſuppoſed to partake of the odour and taſte of moſt other ſpices. The tree grows in great abundance in the iſland of Jamaica, where its fruit is made a conſiderable branch of trade; is generally gathered a little before it acquires full growth, and dried in the ſun ten or twelve days, is then packed up ready for exportation to Europe.

[4]MYRTUS *Dioeca.*

*Dioecious American Myrtle.*] Riſes with an upright tree-ſtem, branching many feet high; oblong, thick, oppoſite, odoriferous leaves; and at the axillas and ends of the branches pedunculi dividing into trichotomous panicles of dioecious flowers; ſucceeded by ſmall, globular, ſpicey berries.

Every part of the tree is a ſtrong aromatic.

[5]MYRTUS *Braſiliana.*

*Braſilian Inodorous Myrtle*] Riſes with a branching ſtem, having a whitiſh bark; broad, oval, ſhining, oppoſite, inodorous, or ſcentleſs leaves, and naked pedunculi, ſuſtaining ſolitary flowers with ciliated petals; ſucceeded by large oval fruit.

All theſe five ſpecies of Myrtus are exotics of the ſhrub and tree kind, though in this country, as being confined in pots, the largeſt of them aſſume only the growth of moderate ſhrubs. The firſt ſpecies, Common Myrtle, is conſiderably the moſt noted ſpecies of this genus in this country; where in moſt of our green-houſe collections one or other of the varieties is found in tolerable plenty; but all the varieties of it highly merit notice. The other four ſpecies are rare in England, they however are retained in many curious gardens, in the ſtove collection, more particularly the *Pimento*, which is a very beautiful odoriferous ever-green, and exhibits a fine variety in the ſtove at all ſeaſons: in ſhort all the ſpecies, both green houſe and ſtove kinds, have a pretty effect as ever-greens, and ſome of the ſorts flower very ornamentally, particularly of the Common Myrtle.

With reſpect to flowering, all the varieties of the *Myrtus Communis* flower here in July and Auguſt, moſt of which are very floriferous, but more particularly the broad-leaved Roman kind, which is often covered with flowers; and in ſome of the ſorts are ſucceeded here by berries ripening in winter. Some of the ſtove kinds alſo flower here, but are rarely ſucceeded by fruit in England.

The flowers, however, of moſt of the ſorts are ſmall, but numerous; and are all formed each of five oval petals, and many ſtamina. See the *Characters.*

As all the ſpecies require occaſional ſhelter here, they muſt be kept always in pots, for moving to the proper places of ſhelter, according to their nature; the *Myrtus Communis* and varieties to the green-houſe in winter; the others to the ſtove, to remain all the year; therefore let all the ſorts be potted in light rich earth, and, as they advance in growth, ſhift them into larger pots, managing the Myrtles as other green-houſe ſhrubs; and the ſtove-kinds as other woody exotics of the ſtove. See their *Propagation and General Culture*; alſo GREEN-HOUSE and STOVE PLANTS.

But, as we before obſerved, the broad-leaved *Myrtus Communis*, being hardier than the ſmaller-leaved kinds, ſome of them may alſo be turned out into the full ground in a warm ſituation againſt a wall, &c. allowing them ſhelter of mats in froſty weather, and mulch the ground over their roots: they will frequently ſucceed tolerably, and effect a good variety in ſuch places.

*Propagation and General Culture.*

The propagation of the *Myrtus Communis* and varieties is effected abundantly by ſlips

or cuttings, alſo by layers; but as the former ſtrike freely, it is the moſt eligible method for raiſing any conſiderable quantity, as alſo the handſomeſt plants, which may be ſtruck either in natural earth, or by aid of hot-beds, to bring them more forward.

By Slips and Cuttings.—The young ſhoots, either of the ſame or former year's growth, of from about two or three to five or ſix inches long, either ſlipped or cut off, are the proper parts for planting; and, as above ſaid, may be ſtruck either in natural earth without artificial heat, or by aid of hot-beds; but by the latter you may greatly facilitate the rooting and firſt effort of growth. By either method the work may be performed any time from March or April until Auguſt, though June or July is the moſt common ſeaſon practiſed, eſpecially when intended to uſe the ſhoots of the year, which are generally in prime order in July, and often ſtrike freely the ſame year without aid of hot-beds; the young ſhoots of the former year will alſo often ſtrike tolerably, eſpecially if planted in ſpring or early in ſummer, or by aid of hot-beds may be made to ſtrike root readily at any time in the ſpring or ſummer ſeaſon. By aid of a hot-bed, however, all the ſorts, both of one or two years ſhoots, may be greatly facilitated in rooting: a dung hot-bed under common frames and lights will do, though a bark hot-bed of a ſtove, &c. is conſiderably the moſt eligible and effectual, and may be readily uſed any time in ſpring and ſummer for this purpoſe; and by which aſſiſtance vaſt numbers of cuttings may be ſtruck with the utmoſt facility in a ſhort time, with but little trouble; and plants thus ſtruck in ſpring or early in ſummer, may be ſo much forwarded as to form pretty little plants the ſame year, and be fit to pot off ſeparately early in autumn. We will, however, exhibit ſeparate directions for both methods, i. e. ſtriking them in natural earth, and by hot-beds.

Firſt, by ſtriking them in natural earth: we noticed above, that the planting might be performed any time from March till Auguſt; obſerve in reſpect to this, that if you would begin in ſpring, or early in ſummer, you muſt chuſe principally the ſhoots of the former year; and if you do not begin planting till June or July, but particularly the latter month, the young ſhoots of the year will be arrived at a proper growth, and will root freely. Obſerve in chuſing the ſhoots, either of the former or ſame year, to chuſe the ſtraight clean growth, of from about two or three to four or five inches length, and as robuſt as poſſible; which diveſt of the lower leaves, two parts of three of their length, they are then ready for planting; then having ſome large wide garden-pots, or rather flat wide earthen pans, ſix inches deep, with holes at bottom to diſcharge the wet, ſuch as are uſed by the ſetting-gardeners about London, who raiſe prodigious quantities of Myrtle annually for the ſupply of the markets; fill the pots or pans with light rich mould, in which plant the ſlips or cuttings, many in each pot or pan, if required, putting them in within an inch of their tops, and about an inch or two aſunder; give directly ſome water to ſettle the earth cloſely about each plant; then either plunge the pots, &c. in a ſhallow garden-frame, and put on the glaſſes, or under oiled paper-frames, or cover each pot or pan cloſe with a low hand-glaſs, which is rather the moſt eligible for facilitating their rooting; in either method, however, obſerve to plunge the pots in the earth, and keep them cloſe covered with the glaſſes, &c. where practicable, to exclude the air, for this will promote the quick emiſſion of roots the ſame ſeaſon; remembering to afford them occaſional ſhade from the mid-day ſun, but if under oiled paper none is wanted; and give plenty of water three or four times a week at leaſt, or oftener in very hot weather; thus they will be rooted in a month or ſix weeks, which will appear by their exhibiting ſigns of growth at top; at which period inure them gradually to the full air, ſtill ſupplying them duly with water during the hot weather, whereby they will ſhoot in height; and thoſe planted early will often branch out laterally a little the ſame year, ſo as to commence pretty little plants by autumn: let them remain in the full air until October, then remove them in their pots or pans into the green-houſe, or under a good garden-frame for the winter, and in ſpring the forwardeſt in growth may be potted off ſeparately in ſmall pots; but if rather ſmall and weak, or but indifferently rooted, let them have another ſummer's growth, and pot them out ſeparately in September or ſpring following, as it ſhall ſeem proper; managing them as other green-houſe ſhrubs of ſimilar temperature, and ſhift them into larger pots annually, or according as they ſhall require.

For want of frames and glaſſes of any ſort to ſtrike the cuttings under, oiled paper-frames

frames may be uſed, which may be obtained at an eaſy expence, and are excellent for ſtriking many ſorts of cuttings; they admit the rays of light and heat ſufficiently, at the ſame time afford ſuch an agreeable ſhade that no other is required, and which is of ſuch a nature as greatly to promote the rooting of cuttings.

But Myrtle cuttings will ſometimes ſtrike in the open ground without any coverings; and if planted betimes in ſummer, either in pots or pans, as above mentioned, and plunged in a ſhady border, or the ſlips planted in the earth of ſuch a border of rich earth; and in either method plentifully ſupplied with moiſture, they will often root tolerably the ſame year, and ſhoot a little at top; though rarely make ſo good plants by autumn as thoſe forwarded in the above manner, nor near ſo ſtrong as thoſe ſtruck in the following method by aid of artificial heat.

By Aid of Hot-beds.—By the aſſiſtance of hot-beds, either that of dung, under frames and glaſſes, oiled paper-frames, or in the bark-bed in the ſtove, &c. but rather the latter; but by either method the rooting and firſt growth of the ſlips may be greatly forwarded; a bark-bed in particular in the ſtove, &c. is the moſt eligible, and effectual for this purpoſe, and in which vaſt numbers of ſlips or cuttings may be readily ſtruck, at any time from March until Auguſt, both in ſhoots of the former year, and of the ſame year's growth, from three or four to five or ſix inches long: and that thoſe ſtruck in ſpring and early in ſummer, will form fine young plants for potting off early in the proceeding autumn. However, in default of bark hot-beds, one of dung under glaſſes may ſuffice; but if furniſhed with both, give preference conſiderably to a bark-bed.

Therefore being furniſhed with pots, or rather wide pans, as before directed, filled with fine rich earth, take off a quantity of ſlips or cuttings, the moſt robuſt ſhoots; which if in ſpring or early in ſummer, thoſe of the former year muſt be choſen; and at a more advanced ſeaſon, thoſe of the ſame year will be arrived to a proper growth for this purpoſe: obſerving for either ſort to ſtrip off the under leaves, as before adviſed; then plant them in the pots or pans, as already exhibited, give a general watering, and directly plunge them in the hot-bed, affording occaſional ſlight ſhade from the fierce ſun, and water them frequently; they will thus root in a fortnight or three weeks, and advance in growth; obſerving to inure them gradually to the open air, if the temperature of the weather permits, in a ſheltered ſituation; or in a frame, if cold weather, and from thence by degrees expoſe them fully for the remainder of the ſummer, in a ſheltered place, and ſupply them duly with water in dry weather, they will be fine plants by September; and, as before obſerved, thoſe raiſed early will be then fit to pot off ſingly into ſmall pots; and the latter plantings will be fit for potting in ſpring, or autumn following; removing them all to ſhelter towards the middle or latter end of October.

In ſtriking the cuttings by the above method, if, as ſoon as they are planted and plunged in the hot bed, each pot or pan is covered cloſe with a low hand-glaſs, it will ſtill contribute to facilitate their rooting the more effectually; for being cloſe covered, it will force out roots ſooner, and prevent the cuttings from running up weak; obſerving, however, when they begin to advance at top, to remove the glaſſes.

By the above methods of artificial heat, in ſtriking Myrtle cuttings, you may make two or three plantings each ſeaſon, where large quantities are required; the firſt planting in March or April, of the beſt laſt year's ſhoots; the ſecond early in June, of the ſucceeding beſt ſhoots; or about Midſummer, or ſoon after, may plant ſhoots of the year; and in a month or ſix weeks after, the next beſt ſhoots alſo of the ſame year will be come forward, and of which may be made another plantation; plunging each planting in the bark-bed, &c. as above; thus may you have three young crops advancing in different ſtages of growth each year in ſtore-pans; ſome ready for potting off ſingly every autumn and ſpring, whereby a large ſtock may be always kept up, as is neceſſary for thoſe who raiſe them for ſale, eſpecially about London, for Covent-garden market, where amazing quantities are brought for ſale at all times of the year, which ſell from ſix-pence to half a crown per pot, according to the ſize and goodneſs of the plants.

Thoſe who propagate large quantities of theſe plants annually, ſhould always keep ſome ſtrong buſhy plants for furniſhing ſlips or cuttings for this purpoſe.

Propagation by Layers.——Such plants as are furniſhed with young bottom branches or ſhoots ſituated low enough for laying, may

be layed in ſpring, in the uſual way; every ſhoot will readily emit roots, and be fit to tranſplant into ſeparate pots in autumn.

By Seed.—Theſe may be ſowed in ſpring, in pots of light mould, and plunged in a moderate hot-bed; they will ſoon come up, which when two or three inches high, pot them off ſeparately in ſmall pots; manage them as the others, and probably as they advance in growth may diſcover ſome new varieties.

With reſpect to the general culture of all theſe ſorts of common Myrtle, they ſucceed in the open air from May until the end of October, when remove them in their pots to the green-houſe, or into a deep garden-frame under glaſſes, allowing air freely in all mild weather, by opening the glaſſes wide; giving water once or twice a week or ten days in winter, and every other day at leaſt in ſummer; and according as they advance in growth, ſhift them into larger pots, which may be neceſſary every year to one or other of them. See GREEN-HOUSE PLANTS.

In training theſe ſhrubs, obſerve, as they naturally branch out all around, ſo to be feathered quite to the bottom, in a beautiful manner, that if you deſign any ſhall form ſtandards, with buſhy heads for variety, trim off the lower ſhoots gradually ſo as to form a ſtraight clean ſtem, two or three feet high or more, then ſuffer them to branch out every way at top to form a head: but thoſe which are intended to be low and branchy quite to the bottom, ſhould have the lateral ſhoots encouraged nearly in their own way, whereby they will be feathered all the way from bottom to top, and aſſume a more picturesque appearance.

Let them afterwards for the moſt part aſſume their own natural growth, except when their heads become thin, ſtraggling, and irregular; then ſhorten with a knife ſuch ſhoots as ſhall appear proper, either in order to force out laterals to make good deficiencies, or to form regularity.

Never practiſe clipping theſe ſhrubs with garden-ſhears into globes, pyramids, &c. as ſometimes done; but let all neceſſary trimming be performed by knife, and that only in caſes of irregularity as above, for they always appear the moſt agreeable when they grow nearly according to nature.

If their heads at any time become very irregular, or thin and ſtubby, by heading down all the branches pretty ſhort in ſpring, and ſhifting them into larger pots of freſh mould, with the ball of earth about their roots, affording plenty of water all ſummer, they will all branch out again numerouſly, and form handſome full heads by the ſucceeding autumn.

Sometimes when Myrtles are become very weak ſtraggling ſhooters, with naked unſightly heads; if headed down, as above, in April or May, turned out of the pots, and plunged in a warm border of rich ſoil, giving plenty of water, they, by ſending their fibres into the freſh earth, often break out with freſh vigour, and become fine full-headed plants by the end of ſummer, when they may be taken up with balls and potted in freſh earth.

As the ſorts in general encreaſe in ſize, ſhift them into larger pots. See GREEN-HOUSE PLANTS and SHIFTING PLANTS.

*Propagation of the Stove Kinds.*

The four kinds of *Myrtus* for the ſtove, are commonly propagated by ſeeds; though, when any are pretty branchy, it may alſo be tried by layers and cuttings.

By Seed.—This is procured from abroad by the dealers, preſerved in ſand, &c. and arrives in ſpring, which ſow as ſoon after they arrive as poſſible, in pots of freſh rich mould, and plunge them in a bark-bed, they will come up the ſame ſeaſon; which, when of two or three inches height, plant out in ſeparate ſmall pots, plunge them alſo in the bark-bed, ſupply them with water, and manage them as other woody plants of ſimilar temperament.

By Layers.—The firſt ſort in particular often branch out low; lay ſome of the young ſhoots in ſpring, by ſlit-laying or wireing, &c. plunging the pots in which they are layed in the tan; they will probably be rooted in one year, though it is frequently two before they ſtrike good root, when pot them off ſeparately.

By Cuttings.——In May or June cut off ſome ſhort young ſhoots from ſuch of the plants as afford them, plant them in pots of freſh compoſt, plunge them in the bark-bed, and cover them cloſe with a low hand-glaſs, giving due refreſhments of water; they will ſoon take good root the ſame year, and be fit to plant in ſeparate ſmall pots.

In the general management of theſe ſorts, keep them always in the ſtove, except about a month

a month in the heat of ſummer, when they may be truſted abroad. Let them ſhoot nearly in their own way, keeping them, however, to upright ſtems, and ſuffer their heads to branch out according to nature, except juſt reducing very irregular ſhoots: give frequent waterings in common with other woody plants of the ſtove department, and ſhift them occaſionally into larger pots. See STOVE PLANTS.

# N.

NARCISSUS *(Narciſſus)* Daffodil.

This genus retains a numerous family of eminent, bulbous-rooted, herbaceous perennials of the flowery race, for embelliſhing the pleaſure-garden, having all large tunicated, bulbous roots, crowned with ſeveral long narrow leaves, and erect naked flower-ſtalks, riſing from about eight or ten to fifteen or eighteen inches high, each terminated by a ſpatha, protruding one or more large hexapetalous flowers, having a large cup-ſhaped nectarium in the centre.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, is an oblong, compreſſed ſpatha, opening on one ſide, and withering. COROLLA, ſix large, oval petals, inſerted into, and ſurrounding a large cup-ſhaped nectarium; the nectarium is monopetalous, and placed directly in the centre of the corolla, and reſembles a ſort of cup or diſh. STAMINA, ſix ſhort awl-ſhaped filaments affixed to the tube of the nectarium, and oblong antheræ. PISTILLUM, a roundiſh three-cornered germen below the corolla, long ſlender ſtyle, and trifid ſtigma. PERICARPIUM, a roundiſh, obtuſe trigonous, trilocular, trivalvular capſule, having numerous roundiſh ſeeds.

To this celebrated genus belong alſo all the ſorts of *Jonquilla*, or Jonquil.

There are about twelve ſpecies, ſome of them furniſhing a numerous train of beautiful varieties; one of the ſpecies, Common Daffodil, grows wild in England, &c. but it nevertheleſs poſſeſſes merit as a garden-flower: moſt of the others are originally of foreign growth, but are hardy enough to proſper in our flower-borders, and ſeveral of which have long adorned our gardens. All of them produce their flowers from a ſpatha or ſheath; ſome having but one, and ſome many flowers from the ſame ſpatha, though the greater part are uniflorous, but the multiflorous kinds, called *Polyanthos Narciſſus*, having ſuperior merit, are in moſt eſteem among the floriſts; but all the ſorts are very ornamental flowers.

Each flower of all the ſpecies of this genus being furniſhed with that appendage, called *nectarium*, which in theſe plants is always placed in the centre of the corolla, and which, as it in ſhape reſembles a ſort of cup or little diſh, among gardeners it is commonly, but erroneouſly called the cup; therefore in the following deſcriptions of the ſpecies, when we occaſionally mention the cup, it muſt always be underſtood the nectarium.

The ſpecies are;

1 NARCISSUS, *Pſeudo-Narciſſus.*

*Baſtard Narciſſus, or common Yellow Engliſh Daffodil.*] Hath a large, oblong, bulbous root; ſending up ſeveral long, narrow, light-green leaves, a foot long and half an inch broad, a little hollow along the middle; amidſt them, an upright flower-ſtalk, twelve or fifteen inches high; terminated by an uniflorous ſpatha, protruding one large yellow flower, having oval petals, and a bell-ſhaped, erect, golden cup or nectarium, waved, and equal in length with the corolla; flowering in March and April.

*Varieties of this are.*] Common ſingle-flowered pale yellow Daffodil—deep-yellow——golden-cupped——double-flowered——long tubed-flowered——ſhort tubed—dwarf-ſtalked.

This

This ſpecies grows wild in great plenty in many of our woods and coppices, and under hedges in ſeveral parts of England; from which places in the counties round London the herb folks bring prodigious quantities in the ſpring of the year, when in bloom, root and all, and ſell them about the ſtreets. Its commonneſs renders it of but little eſteem with many; conſidered, however, as an early and elegant flower, together with its exceeding hardineſs, and eaſy culture, are ſufficient merits to entitle it to a place in every garden.

[2]NARCISSUS *Bicolor.*

*Two-coloured Incomparable Narciſſus.*] Hath a large, oblong, bulbous root; crowned with long, narrow, dark-green leaves, twelve or fourteen inches long; an upright flower-ſtalk, about fifteen inches high, terminated by an uniflorous ſpatha, protruding one large flower with white petals, and a bell-ſhaped, ſpreading, golden nectarium, waved on the margin, and equal in length with the corolla; flowering in April.

*Varieties.*] Common ſingle-flowered——ſemi-double-flowered—double-flowered——double-flowered, with the interior petals ſome white, and ſome yellow——with ſulphur-coloured flowers.

[3]NARCISSUS *Poeticus.*

*Poetic Daffodil, or common White Narciſſus.*] Hath a large bulbous root; crowned with ſeveral long, narrow, light-green leaves, a foot in length, and near half an inch broad, a little hollow along the middle; amidſt them an upright flower-ſtalk twelve or fifteen inches high, terminated by an uniflorous ſpatha, protruding one large, expanded, nodding, pure-white flower, having a ſhort rotated or wheel-ſhaped nectarium, ſlightly crenated and fringed on the border with a purple circle; flowering in May, and is of exceeding fragrance.

*Varieties.*] With purple-cupped flowers—yellow-cupped flowers—double-flowered: all of them with entire white petals.

This ſpecies is the ancient celebrated *Narciſſus* of the Greek and Roman poets, which they ſo greatly extol for its extreme beauty and fragrance.

[4]NARCISSUS *Bulbocodium.*

*Bulbocodium, Yellow Daffodil, commonly called Hoop-petticoat Narciſſus.*] Hath a ſmall bulbous root, crowned with ſeveral narrow, ſubulate, ruſh-like leaves, ſix or eight inches long; amidſt them a ſlender, taper flower-ſtalk, ſix inches high, terminated by an uniflorous ſpatha, protruding one yellow flower, having the nectarium much larger than the petals, and very broad and ſpreading at the brim; flowering in April.

From the large ſpreading nectarium of this ſpecies, which being three or four times longer than the petals, narrow at bottom, and widening gradually to the brim, ſo as to reſemble the ſhape of ſome old-faſhioned hoop-petticoats, it obtained the name Hoop-petticoat *Narciſſus.*

[5]NARCISSUS *Serotinus.*

*Late-flowering ſmall Autumnal Narciſſus.*] Hath a ſmall bulbous root; crowned with a few narrow leaves; amidſt them a jointed flower-ſtalk, eight or nine inches high, terminated by an uniflorous ſpatha, protruding one white flower, having a ſhort, ſix-parted, yellow nectarium; flowering in autumn.

[6]NARCISSUS *Tazetta.*

*Tazetta, or Multiflorous Daffodil, commonly called Polyanthos Narciſſus.*] Hath a very large, roundiſh, bulbous root; long, narrow, plane leaves; an upright flower-ſtalk, riſing from ten or twelve inches to a foot and a half high; terminated by a multiflorous ſpatha, protruding many large, ſpreading, white and yellow flowers in a cluſter, having bell-ſhaped nectariums ſhorter than the corolla; flowering in February, March, and April, and is very fragrant.

The varieties of this are very numerous, conſiſting of about eight or nine principal ſorts, each of which having many intermediate varieties.

*Principal Varieties are,*] With entire white flowers in large bunches—with white petals and yellow nectariums—white petals and ſulphur-coloured nectariums—white petals and orange-coloured nectariums—with entire yellow flowers——yellow petals and orange coloured cups——yellow petals and ſulphur-coloured cups——double-flowered of each of theſe varieties: all which are multiflorous, or many flowers in a cluſter from each ſpatha.

Of each of theſe principal varieties are many intermediate ones, as above obſerved, varying from each other in ſome little particulars; amounting in the whole greatly above an hundred in the Dutch floriſts catalogues, each variety diſtinguiſhed by a name according to the fancy of the firſt raiſer of it; which varieties, however, and their names often varying in time and different places, it would be unneceſſary to attempt the enumerating any other here than the above principal ſtanding varieties they are all very pretty flowers, and

and make a charming appearance in the flower-borders, &c. they are alſo finely adapted for blowing in glaſſes of water, or in pots, to ornament rooms in winter.

The name *Polyanthos Narciſſus*, uſually given to this ſpecies, ſignifies Many-flowered Narciſſus, many flowers growing from the ſame ſpatha, in a cloſe head or cluſter, like a truſs of the Polyanthos Primroſe, which has alſo the name *Polyanthos*, from many flowers growing in a head. See PRIMULA.

### *Jonquil Kinds.*

There is but one ſpecies of the true Jonquil, but admits of ſeveral varieties, all of the multiflorous kind, and very pretty ſpring-flowers of delightful fragrance, and have long ornamented many curious flower-gardens.

[7]*Narciſſus Jonquilla.*

*Jonquilla, or Jonquil, ſometimes called Ruſh-leaved Daffodil.*] Hath an oblong, bulbous, brown root; ſending up ſeveral long, ſemi-taper, ruſh like, bright-green leaves; amidſt them an upright green flower-ſtalk, a foot or fifteen inches high, terminated by a multiflorous ſpatha, protruding many yellow flowers, often expanded like a radius, each having a hemiſpherical, crenated nectarium, ſhorter than the petals; flowering in April, and moſtly of a fine fragrance.

*Varieties are.*] Jonquil minor, with ſingle flowers—Jonquil major, with ſingle flowers—ſtarry-flowered—yellow and white-flowered—white-flowered—ſemi-double-flowered—double-flowered—and large double inodorous Jonquil: all of them multiflorous, the ſingles in particular, but ſometimes the doubles produce only two or three flowers from a ſpatha, and the ſingles commonly ſix or eight.

All the ſorts of *Jonquilla* have ſo fine a ſhape, ſo ſoft a colour, and ſo ſweet a ſcent, that they are ſome of the moſt agreeable ſpring flowers.

### *Leſs common Narciſſus Kinds.*

[8]NARCISSUS *Calathinus.*

*Calathinus Multiflorous Yellow Narciſſus.*] Hath a large bulbous root; crowned with long, narrow, plane leaves; and amidſt them an erect, robuſt flower-ſtalk, terminated by a multiflorous ſpatha, protruding many large, entire, yellow flowers, having a bell-ſhaped, ſlightly crenated nectarium, equal in length with the petals.

[9]NARCISSUS *Odorus.*

*Odoriferous, or Sweet-ſcented Starry Yellow Narciſſus.*] Hath a bulbous root; narrow leaves; erect flower-ſtalk, a foot or more high, terminated by a ſub-multiflorous ſpatha, protruding ſometimes but one, and ſometimes ſeveral entirely yellow flowers, having a companulated, ſix-parted, ſmooth nectarium, half the length of the petals.

[10]NARCISSUS *Triandrus.*

*Triandrous Ruſh-leaved White Narciſſus.*] Hath a bulbous root; very narrow, ruſh-like leaves; erect flower-ſtalk, terminated by an uniflorous ſpatha, protruding one ſnowey-white flower, having a bell-ſhaped, crenated nectarium, half the length of the petals, and with moſtly triandrous or three ſtamina.

[11]NARCISSUS *Trilobus.*

*Trilobate Yellow Narciſſus.*] Hath a bulbous root; narrow ruſh-like leaves; and erect flower-ſtalks, terminated by a ſub-multiflorous ſpatha, protruding ſometimes but one or two, and ſometimes ſeveral yellow flowers, having a bell-ſhaped, three-lobed nectarium, half the length of the petals.

[12]NARCISSUS *Minor.*

*Minor Yellow Winter Daffodil.*] Hath a ſmall bulbous root; plane leaves, eight or ten inches long, and more than half a one broad; an erect flower-ſtalk, terminated by an uniflorous ſpatha, protruding one nodding yellow flower, with ſpear-ſhaped petals, having an obconic, ſix-parted, waved nectarium, equal to the length of the corolla; flowering in winter, or very early in ſpring.

All theſe twelve ſpecies of *Narciſſus* are of the bulbous-rooted tribe, and univerſally perennial in root, but annual in leaf and flower-ſtalk; all of which riſing annually in ſpring, immediately from the crown of the bulb, firſt the leaves, and in the midſt of them the flower-ſtalk, one only from each root, entirely naked or leafleſs, each terminated by a ſpatha or ſheath, which opens on one ſide to protrude the flowers, and then withers; the flowers, as before obſerved, are all hexapetalous, each furniſhed with a nectarium in the centre, and are univerſally hermaphrodite; they are large and conſpicuous, appearing moſtly in the ſpring ſeaſon, generally from March or April until June, ſucceeded by ripe ſeed in July; then the leaves and flower-ſtalks decay, and the roots deſiſt from growing for ſome time; at which period of reſt is the only proper time to take up, or tranſplant the

the roots from one place to another, or to ſeparate the off-ſets; for they all multiply abundantly by off-ſet young bulbs from the main root, inſomuch that a ſingle bulb will in one or two years be encreaſed into a large cluſter of ſeveral bulbs, cloſely placed together, and which every ſecond or third year ſhould be taken up at the above period in order to be ſeparated; and each off-ſet ſo ſeparated commences a diſtinct plant, which being planted again in autumn, produces flowers the following ſummer, alike in every reſpect to thoſe of their reſpective parent bulbs. See BULBUS.

All the ſpecies are ſo hardy that they proſper in any common ſoil of a garden: obſerving, however, to allow the finer ſorts of *Polyanthos Narciſſus* in particular, principally a warm dry ſituation; all the others may be planted any where in the open dry borders and flower-beds.

The firſt ſeven ſpecies are thoſe the moſt commonly known in the Engliſh gardens; all of which produce ornamental flowers, but the *Polyanthos Narciſſus* is among the floriſts eſteemed the chief of the *Narciſſus* tribe, both on account of its mode of flowering, i. e. in a large cluſter from each ſpatha, and from the vaſt ſource of variety it affords in the different properties of its flowers; ſo that almoſt every eminent floriſt cultivates this ſpecies and its varieties with great aſſiduity, and are often particularly induſtrious in raiſing new varieties from ſeed, eſpecially the Dutch floriſts; and when any new variety is ſo obtained, it propagates itſelf plentifully by off-ſets of the root like the other ſorts, whereby the ſtock in two or three years will be greatly encreaſed.

With reſpect to the merit of the ſpecies in general as flowering plants, all the ſorts may be conſidered as ſome of the moſt beautiful of our bulbous-rooted ſpring flowers for ornamenting the borders, &c. of the pleaſure-garden; and have a very fine effect when diſpoſed in patches in aſſemblage with other bulbous flowers of the ſpring.

The bulbs or roots of all the ſorts may be had at moſt of the nurſery-gardens, and of the ſeedſmen, at the proper ſeaſon, i. e. from September until Chriſtmas, or even until ſpring.

*Method of Planting, &c. of all the Sorts.*

The beſt general ſeaſon for planting all theſe bulbs is autumn, from about the beginning or middle of September until November, in which they will flower conſiderably ſtronger, as well as furniſh a greater encreaſe of off-ſets than thoſe planted later, or not till ſpring: if, however, ſome roots are retained out of ground until February, they will ſucceed thoſe of the autumnal planting in flowering, whereby you may vary and prolong the continuance of the bloom; but theſe late-planted roots always flower weaker, ſome not at all, and at beſt with inferior beauty, and ſhorter continuance, and furniſh but a bad encreaſe of roots; therefore always conſider autumn as the proper planting ſeaſon for the principal blow.

In planting them, obſerve the following modes of diſpoſition.

Thoſe you deſign to diſpoſe in the open borders or other compartments, in aſſemblage with other bulbous flowers, &c. I ſhould adviſe them to be depoſited in little patches, of about three or four roots in each, planting them either with a blunt dibble, or hole them in with a garden trowel, four inches deep; in which mode of diſpoſition they will ſhew their flowers more conſpicuouſly and ornamental than if planted ſingly, as each patch of plants will diſplay their flowers in a cluſter, which will ſtrike the eye moſt agreeably.

When intended to plant a quantity in beds by themſelves, in order to exhibit a full bloom all together in one place, as is often practiſed to the fine *Polyanthos Narciſſus*, Jonquils, &c. have the beds four feet wide, with foot and a half, or two-feet-wide alleys between; in which beds plant the roots in rows lengthways, nine inches aſunder; planting them either with a blunt-ended dibble, or drill them in with a hoe, about four inches deep, and ſix diſtant in each row, covering them regularly with the earth, and rake the ſurface ſmoothly.

Having planted the roots in either of theſe methods, all the culture they require is to be kept clean from weeds; and they will all flower in due perfection the following ſpring and ſummer.

But the *Polyanthos Narciſſus* and Jonquil, as we formerly obſerved, being of the multiflorous kinds, and conſidered of ſuperior value and beauty; to blow them in the higheſt perfection, curious floriſts beſtow particular care in their culture: ſome prepare beds of compoſt, as for the fine hyacinths, &c. and manage

manage them in the ſame manner, particularly the *Polyanthos Narciſſus:* remark, however, that in default of ſuch prepared compoſts, &c. you need not be under any great anxiety, for they generally ſucceed very well in any good, light, rich earth of a garden, in a warm, ſunny, ſheltered ſituation, with the beds a little elevated above the common level, out of the reach of copious moiſture in winter; ſo having the ground formed into four-feet-wide beds, in which plant the roots in rows nine inches aſunder, as before directed; and in winter and early in ſpring give occaſional ſhelter of mats from cutting froſts and other inclement weather, eſpecially after the flower-buds appear above-ground.

All the ſorts of theſe bulbs, planted in either of the above methods, may be ſuffered to remain in the ground two or three years or more, unremoved; when by their being encreaſed by off-ſets into large bunches, each will ſend up ſeveral flower-ſtalks, and ſhew a large cluſter of flowers, appearing conſiderably more conſpicuous and beautiful than when the flower-ſtalks riſe ſingly: remark, however, it is proper to take up the bulbs in general every third or fourth year, in order to ſeparate the off-ſets, which in that time will be increaſed ſo greatly in number, that the bulbs preſſing cloſe againſt one another, the inner ones will be ſo much compreſſed and weakened, as greatly to impede their efforts for flowering.

But where theſe bulbs are intended for ſale, they ſhould generally be lifted once a year, or once every two years, otherwiſe, as by their growing cloſe in cluſters preſſing againſt one another, they will be flattened thereby, and rendered unſightly, and leſs ſaleable.

The only proper time of year for taking up all the ſorts is ſoon after they have done flowering, when their leaves and flower-ſtalks aſſume a ſtate of decay; at which time of lifting the bulbs, ſeparate them all ſingly, and the ſmaller off-ſets from the larger, reſerving the large roots for planting again in the principal compartments, and the ſmaller may be depoſited in nurſery beds for a year or two, to gain ſtrength, when they will become proper blowing roots; and may then be taken up at the proper ſeaſon, in order for planting where wanted.

When the roots are lifted at the above proper ſeaſon, they may either be planted again directly, or in a month or ſix weeks after; or may be cleaned and dried, and retained out of the ground in a dry room, two or three months or longer, if occaſion ſhall require; but, as before ſuggeſted, I ſhould adviſe the principal part to be committed to the earth again in autumn, i. e. in September, October, or November.

*Blowing them in Glaſſes of Water, &c. in Winter, to ornament Rooms.*

The *Polyanthos Narciſſus*, and the large Jonquills, are alſo in great eſteem for blowing in glaſſes of water, in rooms, in winter and early in ſpring, before thoſe in the open ground come into bloom; any of the other ſpecies may alſo be flowered in the ſame manner; obſerving to procure ſuch roots as were lifted at the proper ſeaſon above mentioned.

The glaſſes for this uſe are a ſort of bottle, of about two or three gill-ſize, narrow and upright, ſix or ſeven inches high, with wide mouths to fit the bulbs, one for each glaſs; and are ſold at all the glaſs ſhops. The ſeaſon for uſing them is, any time in winter, or early ſpring, from October or November till February or March: obſerving to fill them with freſh ſoft water, ſo full as the bottom of the bulb may juſt touch it; ſo place one bulb in each glaſs as aforeſaid, and place the glaſſes in any light warm room near the windows where the ſun comes: the roots will ſoon ſend out fibres downward into the water, and leaves and flower-ſtalks at top, and flower ſtrong and agreeably in the dead ſeaſon of winter, and beginning of ſpring, attended with a delightful fragrance.

The water ſhould always be kept up to the proper height in the glaſſes, adding an entire freſh ſupply every three weeks or a month.

We may ſee many of theſe bulbous-rooted plants blowed in the above manner, in great perfection, in winter and ſpring, in the ſeed-ſhops in London; particularly the *Polyanthos Narciſſus*, and fine Jonquils, Hyacinths, &c.

The ſame plants may alſo be brought to early bloom in pots. Plant the bulbs in pots of light rich earth, which place in a warm room, as directed for the glaſſes, placing them in plates of water occaſionally, when the earth wants moiſtening, and take them out again when moiſt enough; and thus they will blow at an early ſeaſon.

But ſuch as have the advantage of ſtoves, or hot-beds under glaſſes, need only carry their glaſſes or pots of bulbs thither, ſetting the former upon ſhelves, and plunging the

latter into the bark-bed, &c. they will have fine flowers from December till the end of March without much trouble.

We muſt obſerve, that to enjoy the pleaſure of this winter floral-ſcene of theſe kinds, the largeſt bulbs are always to be choſen, otherwiſe it will be impoſſible to compaſs it with any degree of perfection.

The bulbs made uſe of for this purpoſe, although they rarely ſerve for the ſame uſe again, yet they will not be loſt, but may be continued in vigour for encreaſe, provided they are taken out of the glaſſes or pots as ſoon as the flowers are gone off, and after cutting off their tops and fibrous roots, plant them in beds of mould to ſtand till the proper lifting ſeaſon, in the mean time they will there multiply by off-ſets, and thus prove a nurſery to ſupply your pots and glaſſes.

The prices of the roots of *Narciſſus* at the nurſeries and ſeed-ſhops is different according to the ſorts: they are commonly ſold by the hundred, or in proportion. The common Daffodils are cheap enough, generally two or three ſhillings a hundred; and the other uniflorous kinds, both white and yellow ſorts, ſell at from about three to ſix ſhillings per hundred roots; but the *Polyanthos Narciſſus* ſell at a greater price, generally from ten to thirty or forty ſhillings per hundred, eſpecially the fine Dutch varieties, ſome of which often ſell from one to eight or ten ſhillings per ſingle root; the Jonquils are generally from five to ten or twelve ſhillings per hundred, according to their ſize and goodneſs, and whether ſingle or double; and ſome of the largeſt double kinds for blowing in glaſſes, ſell at the rate of thirty or forty ſhillings per hundred: obſerving of the ſpecies of *Narciſſus* in general, that if you have different varieties in each parcel, the prices are generally advanced a little in proportion.

Moſt of the eminent nurſery and ſeedſmen about London import a great variety of the *Polyanthos Narciſſus* annually from Holland, the Dutch being famous for raiſing many new varieties of this ſpecies, and of all other curious bulbous-rooted flowers from ſeed, with which they ſupply this and other countries, and make us pay well for their induſtry.

However, after procuring a few roots of each ſort, you may with care greatly encreaſe the ſtock in two or three years.

*Propagation of all the Sorts.*

The propagation of all the ſorts of Narciſſus, is effected principally by their abundant off-ſets from the roots; alſo by ſeed to obtain new varieties.

By Off-ſets.—All the ſorts encreaſe plentifully by off-ſet-bulbs from the main roots annually; and the proper time for ſeparating them is in ſummer, when they have done flowering, and the leaves and ſtalks begin to decay, as obſerved of other bulbous roots; at which time the roots may either be taken up every year or two, to ſeparate the off-ſets, but ſhould not remain longer unremoved than three years, when each root will be then multiplied by its off-ſets into a large cluſter, and, as we before noticed, it is neceſſary to lift them, eſpecially the principal ſorts, to divide the increaſed parts; reſerving the main bulbs to plant, as before directed, for the ſucceeding year's bloom; and the off-ſets ſhould be ſet in nurſery-rows, drilled in three inches deep, and ſix from row to row; to remain to have one or two years growth, when they will have become large bulbs capable of producing flowers in full perfection; and being then taken up at the proper ſeaſon, may be planted in autumn following, in any place where required.

By Seed.—This mode of propagation is rarely practiſed to any but the Polyanthos Narciſſus, and that principally for the ſake of new varieties: I would obſerve, however, that this work of raiſing them from ſeed is exceedingly tedious, as it will be often ſix or ſeven years before the ſeedlings will flower in perfection; it is nevertheleſs practiſed by many curious floriſts, more particularly thoſe of Holland, who exceed all the world in their patience and induſtry in raiſing ſeedling bulbous flowers, for encreaſing the number of new varieties, which they often ſell at a high price; and the following is the method of raiſing ſeedlings of the Narciſſus kind.

The ſeed ripens in June or July, which ſow ſoon after in pots or boxes of light rich earth, half an inch deep; then place them to have only the morning ſun till October, at which time place them in a full ſunny ſituation for the winter, allowing them ſhelter in ſevere froſts. In March or April they will come up, give frequent ſprinklings of water, and occaſional ſhade from the mid day ſun at their firſt appearance; and as the warm ſeaſon

advances,

advances, move the pots to an eaſtern aſpect, to have only the morning ſun till ten or eleven o'clock. In June or July the leaves will decay, when ſtir the ſurface lightly, and clear off the decayed leaves, all weeds and moſſineſs, then ſift a little fine mould over the ſurface, half an inch thick, repeating it again in October or November; and here let them remain undiſturbed till the third year, each year repeating the above work; and in the third ſummer at the decay of the leaves, take up the bulbs, and ſeparate the largeſt, which plant in beds, by drilling, in rows, five or ſix inches aſunder, and three deep; and the ſmall bulbs you may ſcatter, mould and all, on the ſurface of another bed, and cover them two or three inches deep, with fine earth, which after a a year's growth may be tranſplanted in rows, as above.

In theſe beds let the ſeedlings remain till they ſhew flowers, and after the ſecond year's bloom you will be able to judge of their properties, when mark the good ſorts; and manage them as directed for the blowing roots.

NECTARIUM, (from *Nectar*, or honey) a part of the corolla forming a ſort of appendage to the petals of ſome flowers, and is of various ſtructures, figures, ſizes, and ſituations; is generally hollow, or with a cavity, and appropriated for containing the Nectar or honey under a fluid-form that oozes from the plant, and is ſuppoſed to ſerve ſome ſecret purpoſe of fructification.

The *Nectarium*, however, although a part belonging to the corolla, is conſidered diſtinct from the petals, as differing therefrom in point of ſtructure, form, and ſize; yet is often of the ſame texture of the petals, and often of a different nature.

But the *Nectarium* appears in a wonderful variety of forms, &c. in different genera; in ſome it is united with the petals, in others ſeparate. Its ſituation is ſometimes within, and ſometimes withoutſide of the corolla; ſometimes in the calix, and ſometimes on the germen, filaments, and antheræ. In figure, in ſome ſorts it is in form of a tube, in others like a cup or diſh; in ſome it is wide and ſpreading, often appearing like an additional petal; and in ſome is very large, equalling the whole corolla in ſize, and ſometimes larger, and very conſpicuous; and in ſome flowers it is very ſmall, frequently appearing like a pore, a point, fibres, &c. in ſome it aſſumes a horn-like appearance; ſometimes its ſits cloſe, and in ſome it is elevated upon a ſort of ſtyle, or pedunculi, &c. and in a vaſt variety of other forms.

The Nectarium therefore, in point of ſituation and figure, is exceedingly various in different genera, as before noticed, but is frequently ſituated at the baſe of the corolla; ſometimes in form of a narrow tube, as in ſome monopetalous tubular flowers, the lower part or tube being generally found to contain the *Nectar* we formerly mentioned: in many flowers its ſituation is alſo at the baſe, and ſtretch out behind very conſpicuouſly into a long tube, like a horn or a cock's-ſpur, as in lark-ſpur, naſturtium, toad's flax, columbine, balſamine, orchis, &c. ſometimes it is ſituated in the centre of the corolla, and ſhaped like a cup or a bell, as in *Narciſſus*, and in which it is frequently, but erroneouſly called the cup, in ſome of which ſpecies it is very large and conſpicuous: in ſome genera it is ſwoln like a bladder, and hollow, as in *cypripedium*, or ladies-ſlipper, in which it is ſituated in the midſt of the five petals, in which it is of ſingular ſtructure, very large, and fancied to reſemble the ſhape of a ſlipper, or wooden ſhoe. In paſſion-flowers it is ſituated in the middle of the corolla, conſiſting of many ſhort beautiful fibres, diſpoſed in rays, in three ſeries or circular rows round the ſtyle, forming a ſort of triple crown, exhibiting a ſingularly curious appearance; which is alſo the caſe of the Nectarii in many other genera.

When the Nectarium is diſtinct from the petals, it is commonly very irregular, and affords many ſingular and curious variations.

Any farther deſcription of this ſtriking appendage, or ſuperfluity of the corolla, would be unneceſſary in this place, as being ſo very different in different genera, and both its form and ſituation is attended to in diſcriminating the *characters* of the reſpective genera that are furniſhed with a *Nectarium*.

The Nectarium often furniſhes one of the eſſential marks in diſcriminating the characters of many genera.

Plants which have the Nectarium entirely diſtinct from the petals, that is, not united with their ſubſtance, are commonly poiſonous, ſuch are the *aconitum* or monk's-hood, columbine, dog's-bane, hellebore, *aſclepias* or ſwallow-wort, *nigella*, oleander, *narciſſus*, *dictamnus albus* or white dittany, and ſeveral other ſorts.

NEPETA, Nep, or Cat-mint.

The plants are herbaceous perennials for variety in the pleaſure-garden, and for medical uſe; riſing with ſlender branching ſtems, a foot or two high; garniſhed with heart-ſhaped and lanceolate leaves, and the branches terminated by verticillate ſpikes of monopetalous ringent flowers.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, is monophyllous, tubulous, and five-parted at top. COROLLA, is monopetalous, with a cylindric incurved tube, ringent or gaping at top; the upper lip roundiſh, emarginated, and erect, the under one large, roundiſh, concave, and entire. STAMINA, two long and two ſhort filaments, terminated by incumbent antheræ. PISTILLUM, a quadrifid germen, ſlender ſtyle, and bifid acute ſtigma. PERICARPIUM, none, the ſeeds lodged naked in the calix.

There are twelve or fourteen ſpecies, but not more than one common in the Engliſh gardens, viz.

NEPETA *Cataria.*

*Cataria, or Common Cat-mint.*] Hath a creeping perennial root; many upright ſquare ſtems, branching two feet high; heart-ſhaped, dentated-ſerrated, oppoſite leaves, hoary underneath, each on a long foot-ſtalk; and the branches terminated by whorled ſpikes of white ringent flowers, the under verticilli having ſhort pedicles: flowering in June.

*Varieties.*] Larger Cat-mint—ſmaller Cat-mint—narrow-leaved—blue-flowered—purple-flowered.

This ſpecies and varieties have great fragrance, partaking of mint and penny-royal; is cultivated in gardens both for medicine, and to effect variety in the herbaceous collections,

The name *Cataria*, or Cat-mint, originates from the circumſtance of the cats being ſo remarkably fond of the plant, that they eagerly repair to it, roll themſelves thereon, bite and tear it to pieces, chewing it in their mouths, and often in a ſhort time entirely deſtroy the plants. It has been by ſome obſerved, that if you raiſe this plant from ſeed, and it remains where ſowed, the cats will not meddle with it, but if by ſlips, or if tranſplanted, they will ſoon deſtroy it. Whence proceeds the ſaying——

If you ſet it, the cats will eat it;
If you ſow it, the cats will not know it.

This, however, does not always hold good invariably.

It grows naturally in England by hedge-ſides, and on the ſides of banks, but it has been long admitted an inhabitant of gardens, both for its ſingularity, and for medical uſe.

Its propagation is by ſeed, by parting the roots, and by ſlips or cuttings.

By Seed.——Sow it either in autumn, or early in ſpring, in any bed or border of light earth, and rake them in; and when the ſeedlings are two or three inches high, plant them out in nurſery-beds to remain till autumn, and then tranſplant them where they are remain.

By Parting the Roots.——In autumn or ſpring divide the roots into ſlips, which, being planted ſeparate, will ſoon become good plants.

By Slips or Cuttings of the Branches.—In April, May, or June, ſlip or cut off a quantity of young ſhoots, plant them in the ſhade, and ſupply them with water, they will become good plants by autumn.

NERIUM, *Oleander*, or Roſe-Bay.

This genus comprehends beautiful ever-green flowering ſhrubs for the green-houſe and ſtove, of upright branchy growth, adorned with long, ſpear-ſhaped, ſtiff, ever-green leaves; and large monopetalous, funnel-ſhaped, quinquepartite, nectarious flowers, in cluſters from the ſides and ends of the branches of very ornamental appearance.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is acutely five-parted, ſmall and permanent. COROLLA, is monopetalous and funnel-ſhaped, a ſhort cylindric tube, having the upper part large and divided into five broad, obtuſe, oblique ſegments, and a nectarium terminating the tube, being divided into many hair-like parts, arranged in a coronated form. STAMINA, five very ſhort, awl-ſhaped filaments, terminated by arrow-pointed, connivent antheræ, ending in long threads. PISTILLUM, a roundiſh bifid germen, cylindric ſtyle, and truncated ſtigma. PERICARPIUM, two long, taper, acuminated, univalvular pods, furniſhed with numerous oblong ſeeds, placed *imbricatum*, and crowned with down.

There are about four ſpecies, but not more than one common in the Engliſh gardens, which is the moſt beautiful of all the ſorts, and admits of ſeveral elegant varieties.

NERIUM, *Oleander.*

*Common Oleander.*] Riſes with an upright woody ſtem, branching ſix or eight feet high, having a purple or green bark in different ſorts; long, ſpear-ſhaped, ſtiff-leaves, from about three to five or ſix inches long, and one broad, placed ternate or by threes round the branches; and at the axillas and ends of the ſhoots large looſe bunches of very ornamental flowers of different colours and properties in the varieties. Flowering in July and Auguſt.

*Varieties.*] Red-flowered Oleander—ſcarlet-flowered—white-flowered—broad-leaved double-flowered—ſtriped double-flowered—ſtriped-leaved.

Some of theſe varieties are in ſome authors ranged as different ſpecies; they, however, are only varieties of the above ſpecies of *Nerium Oleander.*

This ſpecies and varieties are not only fine ever-greens, but produce large cluſters of exceeding ornamental flowers: the double-bloſſom kinds in particular have ſuperior beauty, the flowers being very large, and the corolla multiplied in ſeveral ſeries, having ſome reſemblance to middling double roſes; are numerous, very conſpicuous, and fragrant, continuing in ſucceſſion a month or two in full luſtre.

They are exotics from the iſland Crete and India, but all the varieties are hardy enough to ſucceed in the open air here in ſummer, and in a green-houſe in winter.

Obſerve, however, the double-flowered kinds being rather of a more tender temperature than the ſingles, that they generally flower the moſt perfectly when indulged with a ſtove, even if only placed therein, or in a glaſs-caſe, about the time of year they are expected to make an effort for flowering, and their flowers will continue longer in beauty; often exhibiting a ſucceſſion of elegant flowers from July until October.

Let all the ſorts be potted in light rich compoſt, and move them into the green-houſe, &c. in autumn, at the approach of cold weather. Supply them with water once a week in winter, or oftener according as they ſhall ſeem to require, but give more frequent waterings in ſummer, in proportion to the heat and drought of the ſeaſon; and according as they advance in ſize, ſhift them into larger pots of freſh mould: their further general culture is as directed for other ſhrubby green-houſe exotics.

Theſe plants are cultivated at all the nurſeries for ſale.

*Their Propagation.*

Their propagation is by layers, cuttings, and by ſuckers from the root.

By Layers.—This may be performed any time from March until May, but the earlier the better; and the youngeſt lower branches are to be choſen; which lay by ſlit-laying: give plenty of water all ſummer as they ſhall require, and they will be moſtly rooted by the following autumn; but by plunging the pots in which they are layed, in a bark-bed, the rooting of the layers may be greatly forwarded: when properly rooted tranſplant them into ſeparate pots.

By Cuttings.—In ſpring or the early part of ſummer, take off cuttings of the young ſhoots, five or ſix inches long and plant them in large pots of rich mould, which place under glaſſes, and give water and ſhade occaſionally: but if plunged in a bark-bed it will promote and forward their rooting more effectually.

By Suckers.—Suckers often ariſe from the bottom, ſometimes furniſhed with roots, but if not, give each a ſmall ſlit at the loweſt part; then apply freſh mould around it, and fibres will be emitted by the end of ſummer; then take them off and pot them ſeparately.

NICOTIANA, Tobacco-plant.

This genus of plants are tall herbaceous annuals of America, where they are cultivated in vaſt quantities for their leaves, of which is prepared that well-known commodity called *Tobacco*; and are raiſed here in many gardens for variety, which they effect moſt agreeably in their upright growth, and noble large foliage; they riſing each with an upright ſtrong ſtem, from three to ſix or eight feet high, branchy at top; ornamented with large oblong ſimple leaves, from about ten or twelve inches to a foot and a half long, and proportionally broad; and monopetalous infundibuliforme flowers terminating all the branches plentifully in looſe bunches.

Claſs and oder, *Pentandria Monogynia.*

*Characters.*] CALIX, is monophyllous, five-parted and permanent. COROLLA, is monopetalous, infundibuliforme, having a long tube, ſpreading above, there terminating in five parts. STAMINA, five long ſubulate filaments, and oblong antheræ. PISTILLUM, an oval germen, long ſlender ſtyle, and

and capitated emarginated ſtigma. PERICARPIUM, an oval, furrowed, bilocular capſule, opening at top, and numerous kidney-ſhaped ſeeds.

Tobacco was introduced into Europe in the year 1560, diſcovered firſt in the iſland Tobago in America, and by the natives is called *Tobac*, hence the Engliſh appellation Tobacco; but the generic name *Nicotiana* is derived from one Monſ. Nicot, who firſt introduced the ſeed of the plants into the European gardens.

There are about ſeven ſpecies, but the moſt remarkable ſorts known in the Engliſh gardens, are the two following.

[1]NICOTIANA *Tabacum.*

*Tabacum, or Common Virginia Tobacco.*] Hath fibrey roots; an upright, round, ſtrong ſtem, riſing from about five or ſix to eight or nine feet high, dividing near the top into branches; very large, ſpear-ſhaped oval, ſeſſile, decurrent leaves, from ten to eighteen inches long, and half as broad; and the ſtem and branches terminated by looſe panicles of acute pale-red flowers.

*Varieties.*] Great broad-leaved—narrow-leaved.

[2]NICOTIANA *Ruſtica.*

*Ruſtic Hardy Engliſh Tobacco.*] Hath a fibrey root; an upright firm ſtem, riſing three or four feet high; large, oval, entire leaves, having foot-ſtalks; and the ſtem terminated by ſmall looſe panicles of yellowiſh-green obtuſe flowers.

Theſe plants are of the annual tribe; natives of moſt parts of America, but tolerably hardy, ſo as to proſper in our gardens as in their native ſoil: the firſt ſort, however, is rather a little tender while young, requiring generally to be raiſed and forwarded in a hot-bed until May; but the ſecond ſpecies is exceeding hardy, and was the ſort firſt introduced into the Engliſh gardens; and being ſo hardy as to ripen great plenty of ſeeds freely every year, and that from the ſcattered or ſelf-ſown ſeeds in autumn; the plants riſe plentifully the following ſpring without trouble, as if natives of England: from which circumſtances it is often called Engliſh Tobacco. The firſt ſpecies, however, is the fineſt plant, both in its procerity of growth, largeneſs of the leaves, and beauty of its flowers.

They flower here in July and Auguſt: the flowers are collected into cluſters, each flower is of one funnel-ſhaped petal, ſpreading and five-parted above; continuing in ſucceſſion until the end of ſummer; ſucceeded by ripe ſeeds in autum.

The ſeeds of theſe plants are very ſmall, generally about 1000 in each capſule, and the whole produce of a ſingle plant is eſtimated at 360,000.

With reſpect to the merit of theſe ſpecies in this country as garden-plants, they are cultivated in many curious gardens, as ornamental annuals for the pleaſure ground, but more particularly the firſt ſpecies, which obtaining a fine majeſtic ſtature, adorned with moſt luxuriant leaves, and large cluſters of delicate red flowers terminating all the ſhoots; they in the whole exhibit an elegant appearance in autumn. The ſecond ſort has alſo merit enough to recommend it for admittance in a collection in aſſemblage with the others, &c. to effect a greater variety. Both the ſorts are alſo cultivated in ſome gardens for uſe, the leaves are the uſeful part; are in perfection early in Auguſt, juſt when they come into flower, and before the under-leaves begin to wither.

As both the ſpecies periſh annually in winter, a freſh ſupply muſt be raiſed every ſpring.

### *Their Propagation.*

Their propagation is by ſeed annually in March or April, the firſt ſort in a hot-bed, the ſecond in the natural ground.

Firſt Sort.—This being rather a little tender whilſt young, in order to have it brought to perfection as ſoon in the ſummer as poſſible, it is proper to ſow the ſeed in a moderate hot-bed in March or April, covering them near a quarter of an inch deep: they will ſoon come up; allow them freſh air daily, and occaſional waterings; managing them as directed for annuals of ſimilar temperature, ſuch as *chryſanthemum*, African marigolds, &c. and in May or early in June, when the ſeedlings are from about three to ſix inches high, plant them out in moiſt weather, in the open ground: thoſe deſigned for ornament, plant ſingly in the different compartments of the pleaſure-garden, and thoſe intended for uſe may be ſet in rows any where, three feet aſunder; as ſoon as planted give a good watering, and repeat it occaſionally till the plants have got freſh root; and they will ſoon ſet to growing luxuriantly, ſo as to acquire their full ſtature in Auguſt, and continue in beauty till October.

Second

Second Sort.—This ſort being of a hardier nature, you may ſow the ſeeds in any bed or border in ſpring, and rake them in lightly; they will readily come up: when the plants are three inches high, plant them out where they are to remain; or may ſow the ſeed in patches to remain, and thin the plants to one in each patch.

NIGELLA, *(Nigella)* Fennel-flower, or Devil-in-a-Buſh.

This genus conſiſts of hardy, herbaceous, annual flowers for the pleaſure-garden; riſing with upright branchy ſtalks a foot and a half high, adorned with multifid or finely-divided leaves, reſembling thoſe of fennel or dill; and with all the branches terminated by large ſpreading pentapetalous flowers ſingly; and as ſome of the plants being of buſhy growth, and each flower having five or ten long horn-like ſtyles and capſules, and which in ſome ſpecies are cloſely ſurrounded at the ſides and top, by a large, leafy, finely-divided involucrum, forming a ſort of buſh as it were around them; hence originated the ſtrange name, Devil-in-a-Buſh.

Claſs and order, *Polyandria Pentagynia.*

*Characters.*] CALIX, none, only ſome long, finely-multifid, floral leaves, appearing like a perianthium, or a ſort of involucrum. COROLLA, five oval, plane, obtuſe, ſpreading petals, contracted at the baſe; and eight very ſhort bilabiated nectaria placed in a circle. STAMINA, numerous ſhort ſubulate filaments, and compreſſed erect antheræ. PISTILLUM, five or ten oblong, convex, erect germina, ending in the ſame number of very long, awl-ſhaped, revolute, permanent ſtyles, and ſtigmas growing longitudinally. PERICARPIUM, five or ten oblong, compreſſed, accuminated capſules, connected by their inner ſide, and filled with numerous angular rough ſeeds.

There are about five ſpecies, all annuals, remarkable for ſome having five ſtyles, and ſome ten.

[1]NIGELLA *Damaſcene.*

*Damaſcene Five-ſtyled Nigella.*] Riſes with an upright ſtem, branching a foot and half high; garniſhed with finely-multifid leaves, the ſegments long, very narrow and numerous; and large flowers ſurrounded by a long leafy involucrum; and hath five horn-like ſtyles.

*Varieties.*] Common pale-blue-flowered—with white flowers—with double flowers, of both kinds.

[2]NIGELLA *Hiſpanica.*

*Spaniſh Ten-ſtyled Blue Nigella.*] Riſes with an upright branchy ſtem, a foot and a half high; garniſhed with multifid leaves, having broader ſegments; and each branch and ſhoot terminated by one very large blue flower, having ten ſtyles of equal length with the corolla.

*Variety.*] With double flowers.

[3]NIGELLA *Sativa.*

*Sativous Five-ſtyled, White, Ægyptian, Nigella.*] Riſes with an erect branchy ſtem, about a foot and a half high; ſhorter, multifid, ſomewhat-hairy leaves; and each branch terminated by one large white flower, having five ſtyles; ſucceeded by roundiſh prickly capſules.

*Varieties.*] Double-flowered—dwarf-ſtalked—ſweet-ſcented.

[4]NIGELLA *Orientalis.*

*Oriental Ten-ſtyled Yellow Nigella.*] Riſes with an upright ſtem, branching a foot and a half high; long finely-multifid leaves; and at the ends of the branches ſmall yellow flowers, having ten ſtyles, longer than the corolla.

[5]NIGELLA *Arvenſis.*

*Arvenſe, Five-ſtyled, Blue, German Nigella.*] Riſes with a ſlender branchy ſtem, about a foot high; very finely-multifid leaves; and pale-blue naked flowers ſingly, having entire petals, and five ſtyles; ſucceeded by large turbinated capſules.

All theſe five ſpecies are annual, riſing from ſeed in ſpring, and totally periſh in autumn, after having flowered and perfected their ſeeds.

They all flower here in July and Auguſt, the flowers are moderately large, univerſally hermaphrodite, and conſiſt each of five oval plane petals; very long, revolute, permanent ſtyles; ſucceeded by ſeveral oblong compreſſed capſules, all united, each terminated by the permanent ſtyle like horns, generally bending different ways; and each capſule filled with numerous ſeeds, ripening in autumn.

The plants are all very hardy, and grow freely any where in the open compartments.

All the ſorts may be employed in the pleaſure-garden, as plants of variety and ornament in the collection of hardy annuals; but the firſt two ſorts, and varieties, are the moſt commonly known in the Engliſh gardens, and are generally the moſt ornamental in the ſize and beauty of their flowers: obſerving of all the

ſorts, that the double flowered varieties are to be preferred for general culture; all of which being diſpoſed in patches, ſowing the ſeeds at once where they are to remain to flower, they will exhibit a pretty variety in aſſemblage with other annuals.

*Their Propagation, &c.*

Their propagation is by ſeed in the open borders, &c. in March and April: or if ſome are ſowed in autumn, and one or two ſowings performed in ſpring, the autumnal-ſowed plants will flower ſtrong and earlier, and will be ſucceeded in bloom by the ſpring-ſowings, whereby the ſeaſon of flowering will be greatly prolonged.

Sow the ſeed in patches about the borders, at once where you deſign they ſhall flower, for they rarely ſucceed by tranſplantation, covering it near half an inch deep; and when the plants are come up an inch or two high, thin them where too cloſe, to three in each patch, and keep them clean from weeds is all the culture they require; and they will all flower at the proper ſeaſon, and produce plenty of ſeed for future propagation.

As all the ſorts periſh totally in winter, a freſh ſupply muſt be raiſed annually from ſeed, as above.

NURSERY, a moſt uſeful diſtrict of gardening, appropriated for the raiſing and nurſing all ſorts of trees, ſhrubs, and herbaceous plants to a proper growth, for ſupplying and recruiting the different gardens, orchards, plantations, &c.

In the Nurſery-garden are raiſed all the different ſorts of fruit-trees, and fructiferous ſhrubs, by the methods directed for each ſort under their proper genera, nurſing and training them up to a proper ſize and growth for planting in the garden or orchard, where they are finally to remain to produce their fruit.

Likewiſe in the Nurſery is raiſed the vaſt train of foreſt-trees, hardy ornamental trees, and ſhrubs in general, both deciduous and ever-greens of all thoſe kinds, and training them up to a proper ſize for the purpoſes for which they are deſigned in the plantations and pleaſure ground.

And in the Nurſery may alſo be raiſed all the ſorts of hardy herbaceous plants, both fibrous-rooted, bulbous, and tuberous-rooted kinds, for adorning the pleaſure-garden, medical uſe, &c.

All ſorts of the above kinds may be readily raiſed together in the ſame Nurſery in ſeparate compartments.

A Nurſery thus furniſhed with the different ſorts of all kinds of trees, ſhrubs, and herbaceous plants, will prove an inexhauſtible ſource of accommodation both for private and public uſe.

The raiſing or propagation of the numerous kinds is performed by various methods, as by ſeed, ſuckers, layers, cuttings, ſlips, off-ſets, parting the roots, grafting, budding; each of which methods as directed under their proper heads; as alſo in the reſpective articles under their proper genera: and after being raiſed by either of the above methods, and ſtationed in Nurſery-rows, they are to remain until they have acquired a proper growth for their reſpective uſes, then to be tranſplanted into the garden, orchard, plantation, &c. where they are deſigned finally to remain, to effect the ſeveral purpoſes for which they are calculated, either for uſe, ornament, or variety; obſerving, that as a recruit of ſome or other of the various ſorts will be required to be drawn off every year, to ſupply the different gardens and plantations, a freſh ſupply of young plants ſhould alſo be raiſed accordingly every year in the Nurſery, of moſt of the various kinds, ſo as to have this diſtrict always fully ſtocked with all kinds in ſeveral different degrees of growth; ſome in ſeed-beds, others tranſplanted in Nurſery-rows; ſome one year, others two, three, or ſeveral years: all of which ſhould be well attended to, both in private and public Nurſeries, that there may be a ſufficiency of plants of all ſorts for furniſhing every different department of gardening as they ſhall be occaſionally wanted.

In the public Nurſery-gardens they have alſo convenient green-houſes, glaſs-caſes, and ſtoves, with their proper appendages, for raiſing the tender exotics from the warmer parts of the world; each of which departments are always ſtationed in the warmeſt and moſt ſunny ſituation, having their front directly facing the ſouth, to have all poſſible benefit from the ſun's influence; and each principal department having its different appendages, as aforeſaid, which are ſmaller departments of frame-work, ſaſhed and glazed, either adjoining to the main ones, or detached; ſerving as ſeminaries or Nurſeries for raiſing and nurſing the various tender plants to a proper growth for furniſhing the other larger conſervatories.

Thus

Thus a Nurſery ground furniſhing all ſorts of plants of different temperatures, will prove a moſt valuable department of gardening, and its various growths will afford the moſt agreeable ſource of variety at all ſeaſons, which to many will appear as ornamental and deſireable as the moſt elegant pleaſure-ground or flower-garden.

*It's Extent, Soil, Situation, &c.*

With reſpect to the proper extent or dimenſions of a Nurſery, whether for private uſe, or for public ſupply, it muſt be according to the quantity of plants required, or the demand for ſale: if for private uſe, from a quarter or half an acre to five or ſix, may be proper, which muſt be regulated according to the extent of garden-ground and plantations it is required to ſupply with the various ſorts of plants; and if for a public Nurſery, not leſs than three or four acres of land will be worth occupying as ſuch, and from that to fifteen or twenty acres, or more, may be requiſite, according to the demand, though ſome occupy forty or fifty acres in Nurſery-ground.

In the neighbourhood of London, for eight or ten miles round, there are a great number of extenſive public Nurſeries, moſt beautifully furniſhed with a prodigious variety of all ſorts of trees, ſhrubs, and herbaceous plants, of many different degrees of growth, for ſupplying noblemen and gentlemens gardens and plantations, for ſome hundreds of miles diſtant at home and abroad; as alſo all ſorts of ſeeds. Moſt of which Nurſeries are alſo furniſhed with all proper green-houſes, glaſs-caſes, ſtoves, &c. for the raiſing all kinds of curious tender exotics for public ſupply.

With regard to ſoil for a Nurſery, the nature and quality of this, without all diſpute, requires our particular attention. The Nurſery-men generally prefer a loamy ſoil of a moderately-light temperament, if poſſible, ſuch as in moſt of the Nurſery-grounds around London: however, a Nurſery may be of any fat moderately light land, that is fifteen or eighteen inches depth of good working ſtaple, but if two or three ſpades deep it will be the greater advantage; and where there is ſcope of ground to chuſe from, always prefer that where there is a good depth, and naturally rich or fat ſoil, for the ſoil of a Nurſery cannot be too good, notwithſtanding what ſome advance to the contrary; for if the ſoil prove poor and lean, the plants raiſed thereon will be languid, weak, and ſtunty; and no remedy, how artful ſoever, will be able to rectify their conſtitution, eſpecially all the tree-kinds: whereas thoſe raiſed in a good fat ſoil always aſſume a free growth, and advance with ſtrength and vigour. It is not abſolutely requiſite, however, that the ſoil ſhould be exceedingly rich, nor over carefully manured, a medium between the two extremes is beſt. A good freſh fat ſoil, ſuch as any good paſture, which having the ſward trenched to the bottom, is excellent for the growth of trees; any good fat ſoil of corn-fields is alſo extremely proper; or any other good ſoil of the nature of common garden-earth is alſo very well adapted for a Nurſery.

As to ſituation; if this is rather ſomewhat low it will be the better, becauſe it is naturally warmer, and more out of the power of cutting and boiſterous winds than a higher ſituation; though if it happens where ſome parts of the ground is high and ſome low, it may be an advantage, the better to ſuit the nature of the different plants. It it alſo of ſingular advantage to have a Nurſery-ground fully expoſed to the ſun and free air, and, if poſſible, where there is the convenience of having water for the occaſional watering of ſeedlings, and ſome newly tranſplanted plants.

And as to a Nurſery for private uſe, with regard to its place of ſituation, reſpecting the other garden diſtricts, that, where there is room, it may either be entirely detached, or may be ſomewhat contiguous to the outer boundaries of the ſhrubbery plantations of the pleaſure-ground, and ſo contrived as to lead inſenſibly into it by winding walks, ſo as to appear part of the garden.

*It's Fences, Preparing and Dividing the Ground.*

A fence round the whole ground is neceſſary: this may either be a hedge and ditch, or a paling; the former is the cheapeſt, and in the end the moſt durable; though in ſome places where hares and rabbits abound, paling fences at firſt are eligible, for preſerving the Nurſeries from the depredations of thoſe animals, which often do great miſchief to the young plants, by barking and cropping them: a good hedge-and-ditch-fence, however, may be made very effectual againſt the inroads of both men and brutes; and the moſt eligible plants for this purpoſe is the haw-thorn; for the method of raiſing of which, and forming a

proper hedge of them, ſee CRATÆGUS *Oxyacantha* and HEDGES.

The ground muſt then be all regularly trenched one or two ſpades deep, according as the natural depth of the ſoil will admit, for by no means dig deeper than the natural good ſoil, let it be either one, one and a half, or two ſpades deep; obſerving the ſame general method as directed under the article *Digging by Trenches*; ſee DIGGING.

Then, having trenched the ground, proceed to divide it by walks into quarters, and other compartments; a principal walk ſhould lead directly through the middle of the ground, which may be from five to eight or ten feet wide, according as it ſhall ſeem proper for uſe or ornament, having a broad border on each ſide: another walk ſhould be carried all round next the outward boundary, four or five feet wide, leaving an eight or ten-feet border next the fence all the way; then may divide the internal part by croſs walks, ſo as to form the whole into four, ſix, or eight principal diviſions, which are commonly called quarters.

*Sowing and Planting this Department with the proper Seeds, Plants, &c.*

One or more of the diviſions muſt be allotted for a ſeminary, i. e. for the reception of all ſorts of ſeeds, for raiſing ſeedling plants to furniſh the other parts; therefore divide this ſeminary-ground into four-feet-wide beds, with foot-wide alleys at leaſt between bed and bed: in theſe beds ſhould be ſowed ſeeds, &c. of all ſuch trees, ſhrubs, and herbaceous plants as are raiſed from ſeed; and which ſeeds conſiſt of the various ſorts of kernels and ſtones of fruit, to raiſe ſtocks for grafting and budding; ſeeds of foreſt-trees, ornamental trees, ſhrubs, &c. and ſeeds of numerous herbaceous perennials, both of the fibrous-rooted and bulbous-rooted tribe; the ſowing ſeaſon is both ſpring and autumn, according to the nature of the different ſorts, which is fully illuſtrated under their proper genera; and when the young tree and ſhrub ſeedling-plants ſo raiſed, are one or two years old, they are to be planted out in Nurſery-rows into the other principal diviſion; but many kinds of herbaceous plants require to be pricked out from the ſeed-beds, when but from two to three or four months old, as directed for each under their own reſpective heads. On the other hand, moſt kinds of bulbous ſeedlings will not be fit for planting out in leſs than one or two years.

Another part of the Nurſery-ground ſhould be allotted for ſtools of various trees and ſhrubs, for the propagation by layers, by which vaſt numbers of plants of different kinds are propagated. Theſe ſtools are ſtrong plants of trees and ſhrubs, planted in rows three or four feet diſtance every way, and ſuch of them as naturally riſe with tall ſtems, are, after being planted one year, to be headed down near the ground, to force out many lower ſhoots conveniently ſituated for laying. See LAYERS and STOOLS.

The other principal diviſions, therefore, of the Nurſery-ground, is for the reception of the various ſorts of ſeedling-plants from the above ſeminary-quarters; alſo for all others that are raiſed from ſuckers, layers, cuttings, &c. there to be planted in rows from one to two or three feet aſunder, according to their natures: obſerving to allow the tree and ſhrub-kinds treble the diſtance of herbaceous perennials. Of the tree and ſhrub kinds ſome are to be planted for ſtocks to graft and bud the ſelect ſorts of fruit-trees upon, and other choice plants, which are uſually propagated by thoſe methods; others are trained up entirely on their own roots without budding and grafting, as in moſt foreſt and other hardy tree kinds; as alſo almoſt all the ſorts of ſhrubs: particulars of all which are exhibited, each under its proper genus. Here they are to remain to have two, three, or ſeveral years growth, according as they ſhall require for the ſeveral purpoſes for which they are deſigned in their future ſituations in the garden, &c. which is directed in their reſpective cultures.

*The Methods and Seaſons for Raiſing and Tranſplanting the various Plants of this Department.*

With regard to the manner of performing the various methods of propagation for raiſing the numerous Nurſery-plants, is fully exhibited alſo under the following heads, in the courſe of this work: *ſowing ſeeds—layers—cuttings—ſuckers—ſlips—off-ſets—parting roots—grafting—inoculation.* And the ſorts that are uſually propagated by either of thoſe methods, are pointed out under their ſeveral reſpective heads, with particular directions of the ſeveral ways each method is performed on the different kinds.

The ſeaſon for performing the works of ſowing, planting, &c. is different in different kinds,

kinds, but autumn and ſpring are the principal ſeaſons.

Some ſorts require to be ſowed in autumn, others not till ſpring, which is particularly explained for the various ſorts under the articles themſelves.

And as to planting or tranſplanting, the principal ſeaſon is from October until March, or even until April for tender kinds, eſpecially many of the ever-green tribe; but all hardy trees and ſhrubs may be tranſplanted any time in winter, in open mild weather from October until March, as juſt obſerved; and for the tender kinds of ever-greens, &c. early in autumn, or not till ſettled weather in ſpring, is the proper time to remove theſe ſorts.

But as to hardy herbaceous fibrous-rooted plants, they may be tranſplanted almoſt any time in autumn or ſpring; even many ſorts in ſummer, when planting them out from the ſeminary: obſerving, however, autumn and ſpring is the proper planting-ſeaſon for older or larger plants; and which are alſo the only proper ſeaſons for dividing or ſlipping the roots of all theſe kind of plants for encreaſe.

And for bulbous-rooted kinds, and all ſuch tuberous roots whoſe leaves decay in ſummer, the proper ſeaſon for planting or tranſplanting them is from May or June until the beginning of Auguſt, when their flower-ſtalks decay, which in ſome ſorts happens early and ſome late in the ſummer; but as ſoon as it happens in the different ſorts, is the only proper time to remove all thoſe kind of plants when neceſſary, as alſo to ſeparate their off-ſets for encreaſe; and which may either be planted again directly, or kept out of ground one, two, or ſeveral months, though it is proper to plant the principal part again in autumn, unleſs where any is to be retained for ſale.

Succulent-perennials may be tranſplanted almoſt any time from March or April until Auguſt or September, which is the beſt ſeaſon for removing theſe kinds, and moſt kinds of ſucculent cuttings, ſucceed beſt when planted in ſummer.

### *General Mode of arranging the Plants of this Department.*

In the diſtribution of all the various ſorts of plants in in the Nurſery, let each ſort be ſeparate: the fruit-trees ſhould generally occupy ſpaces by themſelves; the foreſt-trees, &c. ſhould alſo be ſtationed together; all the ſhrub-kind ſhould alſo be ranged in ſeparate compartments; allot alſo a place for herbaceous perennials; a warm place ſhould likewiſe be allotted for the tender kinds, and incloſed with yew hedges, or a reed hedge, &c. in which compartments you may ſtation all ſuch plants that are a little tender whilſt young, and require occaſional ſhelter from froſt, yet are not ſo tender as to require to be houſed like green-houſe plants, &c. ſo that in ſuch compartments there may alſo be frames of various ſizes, either to be covered occaſionally with glaſs-lights, or with mats, to contain ſuch of the more choice of the above tender kinds in pots, to be nurſed up a year or two, or longer, with occaſional ſhelter, till hardened gradually to bear the open air fully.

The arrangement of all the ſorts in the open grounds, muſt always be in lines or Nurſery-rows, as we formerly obſerved, to ſtand till arrived at a proper growth for drawing off for the garden and plantations; placeing the fruit-tree ſtocks, &c. for graſting and budding upon, in rows two feet aſunder, if for dwarfs; but ſtandards two feet and a half, and a foot and half in the lines (ſee STOCKS); though after being grafted and budded, they then commencing fruit-trees, &c. that if they are to ſtand to grow to any large ſize, they ſhould be allowed the width of a yard between the rows. Foreſt-trees ſhould alſo be placed in rows from two to three feet aſunder, and half that diſtance in the rows; varying the diſtance both ways according to the time they are to ſtand: the ſhrub kind ſhould likewiſe be arranged in rows about two feet aſunder, and fifteen or eighteen inches diſtant in each line; and as to herbaceous plants, they ſhould generally be diſpoſed in four-feet-wide beds, in rows from ſix to twelve or eighteen inches aſunder, according to their nature of growth, and time they are to ſtand.

By the above arrangement of the various ſorts of hardy trees, ſhrubs, and herbaceous plants, in rows at thoſe ſmall diſtances in the Nurſery, a prodigious number of plants are contained within a narrow compaſs, which is ſufficient room, as they are only to remain a ſhort time; and that by being thus ſtationed in a little compaſs, they are more readily kept under a proper regulation for the time they are to remain in this department.

But in the public Nurſeries they often plant many kinds of ſeedling-trees and ſhrubs in much cloſer rows at firſt planting out, than the diſtances above preſcribed, not only in order to huſband the ground to the beſt advantage, but by ſtanding cloſer, it encourages

the ſtem to ſhoot more directly upward, and prevent them expanding themſelves much any where but at top, as for inſtance, many ſorts of ever-greens that are but of ſlow growth the firſt year or two, ſuch as the pine-trees, firs, and ſeveral others; which the Nurſery-gardeners often prick out from the ſeminary, firſt into four-feet-wide beds, in rows lengthways, ſix inches aſunder; and after having one or two years growth here, tranſplant them in rows a foot aſunder; and in a year or two after give them another, and final tranſplantation in the Nurſery, in rows two or three feet aſunder, as obſerved above; and by theſe different tranſplantings, it will encourage the roots to branch out into many horizontal fibres, and prepare them better for final tranſplantation, which is the more particularly neceſſary in ſeveral of the pine and fir kinds, and ſeveral other ever-greens, as is more fully exhibited under their proper genera.

With reſpect to the different methods of planting the various ſorts of Nurſery-plants, after being raiſed either by ſeed, layers, cuttings, &c. it is performed in ſeveral ways to different ſorts; ſome are pricked out by dibble, others are put in by the ſpade, either by trenches, ſlitting-in, trenching, or holing; and ſome are drilled in by a ſpade or hoe.

As to moſt of the tree and ſhrub-kind, ſometimes the young ſeedling-trees and ſhrubs are pricked out from the ſeminary by dibble; ſometimes they are put in by the ſpade in the following methods: firſt, having ſet a line to plant by, ſtrike the ſpade into the ground with its back cloſe to the line, and give another ſtroke at right angles with it; then ſet a plant into the crevice made at the ſecond ſtroke, bring it cloſe up into the firſt-made crevice even with the line, and preſs the mould cloſe to it with the foot; then proceed to plant another in the ſame way, and ſo proceed till all is planted. A ſecond method is for plants with rather larger roots: ſtrike the ſpade down with its back cloſe to the line, as aforeſaid, and then with a ſpade cut out a narrow trench, cloſe along the line, as practiſed in planting box-edgings (ſee BUXUS), making the ſide next the line perfectly upright; then placing the plants upright againſt the back of the trench cloſe to the line, at the proper diſtances, before mentioned; and as you go on, trim in the earth upon their roots: and when one row is thus planted, tread the earth gently all along cloſe to the plants; and then proceed to plant another row. A ſecond method of planting-out ſmall tree and ſhrub plants is, having ſet the line as above, then turning the ſpade edgeways to the line, caſt out the earth of that ſpit, then a perſon being ready with plants, ſet one in the cavity cloſe to the line, and directly taking another ſuch ſpit, turn the earth in upon the roots of the plant, and then placing another plant into the ſecond cut, cover its roots with the earth of a third ſpit, and ſo on to the end: but ſometimes when the roots are any thing larger, holes are made along by the line wide enough to receive the roots freely every way, ſo covering them in, as above, as you go on: obſerving always to preſs the earth gently with the foot cloſe to the roots, and cloſe about the ſtems, to ſettle the plants firmly in their proper poſition.

Herbaceous fibrous-rooted plants are, for the moſt part, planted with a dibbie, except when the roots are large and ſpreading, or ſuch as are removed with balls of earth; then they are more commonly planted by hoieing them in with a garden trowel, or ſmall ſpade.

Bulbous and tuberous-rooted plants, ſuch as lilies, tulips, anemonies, ranunculas, &c. are very commonly planted with a dibbie, but many ſorts may alſo be drilled in with a hoe, ſee DRILL-SOWING, &c. Theſe ſorts are alſo ſometimes planted as follows: rake or trim the earth from off the top of the beds from about three to four or five inches deep, into the alleys, then place the roots in rows upon the ſurface, and immediately cover them with the earth which was drawn off into the alleys for that purpoſe, ſpreading it evenly over every part, ſo as to bury all the roots an equal depth.

But as to the tender kinds of exotic-plants that require occaſional ſhelter whilſt young, many of them ſhould be potted, in order for moving to a warm ſituation in winter, or ſome into frames, &c. to have occaſional ſhelter from froſt, by glaſſes or mats, as they ſhall require; hardening them, however, by degrees to bear the open air fully in the Nurſery the year round.

And the moſt tender kinds that require the aid of a green-houſe and ſtove, muſt all be potted, and placed among the reſpective plants of thoſe conſervatories. See GREEN-HOUSE and STOVE PLANTS.

*General Culture of the Plants of this Department.*

With reſpect to the management of the various hardy Nurſery-plants;

Thoſe

Thoſe deſigned as ſtocks for fruit-trees, ſhould have their ſtems generally cleared from lateral ſhoots, ſo as to form a clean ſtraight ſtem, but never to ſhorten the leading ſhoot, unleſs it is decayed, or becomes very crooked, in which caſe it may be proper to cut it down low in ſpring, and it will ſhoot out again; training the main ſhoot for a ſtem, with its top entire for the preſent, till grafted or budded; and as to the grafting and budding them, that work is fully directed under theſe articles, and their general method of training, whether for dwarfs or ſtandards, is alſo particularly exhibited under thoſe two heads, and in the reſpective genera of the various ſorts.

Foreſt-trees ſhould alſo be encouraged to form ſtraight clean ſtems, by occaſional trimming off the largeſt lateral branches, which will alſo promote the leading top-ſhoot in aſpiring farther in height; always ſuffering that part of each tree to ſhoot at full length, that is not to top it, unleſs, however, where the ſtem divides into forks, to trim off the weakeſt, and leave the ſtraighteſt and ſtrongeſt ſhoot or branch, to ſhoot out at its proper length to form the top, as above.

The different ſorts of ſhrubs may either be ſuffered to branch out in their own natural way, except juſt regulating very irregular growths; or ſome may be trained with ſingle clean ſtems, from about a foot to two or three high, according as you ſhall think proper with reſpect to the ſorts or purpoſes for which you deſign them in the ſhrubbery; but many ſhrubs appear the moſt agreeable when permitted to ſhoot out laterally all the way, ſo as to be branchy or feathered to the bottom.

All the fruit-trees, as ſoon as grafted or budded, ſhould each ſpecies have all its different varieties numbered by placing large flat-ſided ſticks at the ends of the rows, for which purpoſe many of the London Nurſerymen uſe the ſpokes of old coach-wheels, or any thing about that ſize of any durable wood, painting or marking the numbers thereon, 1, 2, 3, &c. to different ſticks, entering the numbers in the Nurſery-book, with the name of the varieties to which the number-ſticks are placed; whereby you can at all times readily have recourſe to the ſorts wanted.

The ſame method may be practiſed to any other trees, ſhrubs, or herbaceous plants, eſpecially the varieties of particular ſorts, when they are numerous, ſuch as in many of the flowery-tribe, as auriculas, carnations, tulips, anemonies, ranunculas, and the like.

With reſpect to watering the Nurſery-plants; this may be very requiſite in dry hot weather in ſpring and ſummer, to ſeed-beds and tender ſeedling-plants, while young, and when firſt planted out till they have taken good root; alſo occaſionally to new-layed layers, and newly-planted cuttings in dry warm weather; but as to hardy trees and ſhrubs of all ſorts, if planted out at the proper time, that is, not too late in ſpring, no great regard need be paid to watering, for they will generally ſucceed very well without any: indeed where there is but a few, you may if you pleaſe water them a little, if it proves a very dry ſpring in April and May; but where there are great plantations it would be an almoſt inſupportable fatigue, and great expence; as in many public Nurſeries, where they each winter or ſpring plant out fifty or ſixty thouſand trees and ſhrubs, and in ſome double thoſe numbers.

Every winter or ſpring, the ground between the rows of all ſorts of tranſplanted plants in the open Nurſery-quarters muſt be digged; this is particularly neceſſary to all the tree and ſhrub-kind that ſtand wide enough in rows to admit the ſpade between; which work is by the Nurſery-men called *turning-in*; the moſt general ſeaſon for which work is any time from October or November until March, but the ſooner it is done the more advantageous it will prove to the plants. The ground is to be digged but one ſpade deep, proceeding row by row, turning the top of each ſpit clean to the bottom, that all weeds on the top may be buried a proper depth to rot: this work of *turning-in* is a moſt neceſſary annual operation, both to deſtroy weeds, and to encreaſe the growth of the young Nurſery-plants.

In ſummer be remarkably attentive to keep all ſorts clean from weeds; the ſeedlings growing cloſe in the ſeminary-beds muſt be hand-weeded, but the plants of all ſorts that grow in rows wide enough to introduce an hoe: this will prove not only the moſt expeditious method of deſtroying weeds, but by looſening the top of the ſoil, it will prove good culture in promoting the growth of all kinds of plants: always perform this work of hoeing in dry weather, in due time before the weeds grow large, and you may ſoon go over a large ſpace of ground, either with a large drawing-hoe, or with a ſcuffling hoe, as you ſhall find the moſt convenient. See HOE and HOEING.

Ac-

According as any quarter or compartment of the Nurſery-ground is cleared from plants, others muſt be ſubſtituted in their room from the ſeminary; but the ground ſhould previouſly be trenched and lie ſome time fallow, to recruit or recover its former vigour; giving it alſo the addition of manure, if it ſhall ſeem proper; and after being trenched in ridges, and having the repoſe only of one winter, or ſummer, or a year at moſt, it will ſufficiently recover its vegetative force, and may be planted afreſh.

It will be of advantage to plant the ground with plants of a different kind from thoſe which occupied it before.

The tender or exotic plants of all kinds that require ſhelter only from froſt, whilſt young, as we formerly mentioned, and by degrees become hardy enough to live in the open air, ſhould, ſuch of them as are ſeedlings in the open grounds, have the beds arched over with hoops, or rods, at the approach of winter, in order to be ſheltered with mats in ſevere weather; and thoſe which are in pots, either ſeedlings or tranſplanted plants, ſhould be removed in October in their pots to a warm ſunny ſituation ſheltered with hedges, &c. placing ſome cloſe under the fences facing the ſun, where they may have occaſional covering of mats in froſty weather; others that are more tender may be placed in frames, to have occaſional covering either of glaſs-lights or mats, &c. from froſt; obſerving of all thoſe ſorts here alluded to, that they are gradually to be hardened to the open ground, and need only be covered in froſty weather; at all other times let them remain fully expoſed, and by degrees as they acquire age and ſtrength inure them to bear the open air fully; ſo as when they arrive at from two or three to four or five years old, they may be turned out into the open ground. The ſorts requiring this treatment, are always pointed out under their proper heads, in their reſpective genera.

The green-houſe kinds of all ſorts, or ſuch as require conſtant ſhelter in winter, are to be managed as directed under the article GREEN-HOUSE PLANTS.

And the hot-houſe or ſtove plants, or ſuch as require conſtant ſhelter all the year, together with the aid of artificial heat, are to be managed as exhibited under the article STOVE PLANTS.

NYCTANTHES, Arabian Jaſmine.

This genus conſiſts of ſhrubby, ever-green, very flowery exotics of the Indies, for the ſtove collection; riſing with ſhrubby durable ſtems, branching ten or twelve feet high; adorned with heart-ſhaped, oval, and ſpear-ſhaped, entire leaves; and numerous monopetalous, hypocrateriforme, eight-parted, white, very fragrant flowers in cluſters at the ſides and ends of the branches.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is monophyllous, acutely eight-parted, and permanent. COROLLA, is monopetalous. hypocrateriforme, or ſaucer-ſhaped, with a cylindric tube, divided above into eight plane ſpreading ſegments. STAMINA, two ſmall ſubulate filaments, and acute erect antheræ. PISTILLUM, a roundiſh depreſſed germen, ſimple ſtyle, and two erect ſtigmas. PERICARPIUM, a roundiſh, didymous, bilocular berry, having two roundiſh ſeeds.

[1]NYCTANTHES *Sambac.*

*Sambac, or Common Arabian Jaſmine.*] Hath a ſhrubby, weak ſtem, branching ſtraggling and numerouſly mounting upon ſupport ten or twelve feet high; heart-ſhaped obtuſe leaves below, and oval acute ones above, about three inches long and one broad, placed by pairs oppoſite; and from the upper axillas and ends of the branches ſmall cluſters of pure white, very fragrant flowers, great part of the year.

[2]NYCTANTHES *Undulata.*

*Undulate-leaved Malabar Jaſmine.*] Hath a ſhrubby ſtem, branching eight or ten feet high; having taper branches; oval ſpear-ſhaped, undulate, or waved ſmooth leaves, by pairs oppoſite; and at the axillas ſmall cluſters of large ſnowy-white, ſweet-ſcented flowers.

[3]NYCTANTHES, *Arbor Triſtis.*

*Arbor-triſtis, or Sorrowful-tree, or Mournful Nyctanthes* ] Hath a ſhrubby, tetragonous, or ſquare ſtem, branching numerouſly twelve or fifteen feet high; oval, acute-pointed, oppoſite leaves, and at the axillas cluſters of white, very fragrant flowers, opening at night, and withering in the morning.

From the circumſtance of the flowers of this tree blowing on nights, and fading at the approach of morning, aſſuming a withered mournful appearance in the day-time, it obtained the name *Arbor triſtis, or Sorrowful-tree.*

[4]NYCANTHES *Hirſuta.*

*Hairy Sorrowful-tree.*] Hath a ſhrubby ſtem, branching twelve or fifteen feet high; oval, ſmooth, ſhining-green leaves, placed irregularly, having hairy foot-ſtalks; and at the

the axillas cluſters of white flowers, on hairy pedunculi, opening on nights and fade next morning.

All theſe ſhrubs are beautiful ever-greens, and flower here in our ſtoves annually; the firſt in particular is exceedingly floriferous great part of the year, and make a fine appearance; in all the ſorts the flowers are hermaphrodite, and each is monopetalous, ſalver-ſhaped, and divided above into eight ſpreading ſegments (ſee the *Characters*); thoſe of all the ſorts have ſome reſemblance to the common white Jaſmine, but larger and more divided, and of a higher fragrance, which is ſomewhat like that of orange-flowers.

The plants are all tender exotics from the hot parts of India, &c. require a hot houſe in this country; ſo muſt be kept always in pots of rich earth, and placed conſtantly in that department, except about a month or two in the heat of ſummer, when, if thought proper, they may be ſet abroad; being careful, however, to remove them into the ſtove again early in September.

The firſt ſort is that which is the moſt commonly known in the Engliſh gardens, the others are very rare in this country.

*Their Propagation, &c.*

Their propagation is by layers and cuttings, alſo ſometimes by grafting.

The layers and cuttings muſt be of the young ſhoots, and ſpring or the early part of ſummer is the proper ſeaſon for performing the work, which is to be effected in the uſual way: obſerving, that if the pots containing the layers and cuttings are plunged in the bark-bed, it will forward their rooting exceedingly; each plant is afterwards to be potted ſeparately, and plunged alſo in the bark-bed in the ſtove.

The propagation by grafting is ſometimes practiſed upon ſtocks of the common white Jaſmine, in the uſual method in ſpring: obſerving not to ſuffer any ſhoots to grow from the ſtock below the graft; training the main ſhoot from the graft, a foot or two high to form a ſtem.; then encourage it to branch out to form a head.

Let the plants have a due ſupply of water all the year; and if they grow luxuriant, prune them as you ſhall ſee convenient; and ſhift them into larger pots occaſionally.

NYMPHÆA, *(Nymphæa)* Water-Lily.

The plants are herbaceous, very flowery perennials of the aquatic-tribe, inhabitants of our rivers and brooks; but ſometimes cultivated in canals, ponds, &c. of gardens, for ornament, and have a beautiful effect: they having large knotty roots, ſending up very large heart-ſhaped leaves on long footſtalks, and float on the ſurface of the water; and between them very large polypetalous flowers, on very long pedunculi, and ſhew themſelves alſo juſt above the ſurface of the water, and are exceedingly ornamental.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, four large, coloured, permanent leaves. COROLLA, many petals (generally about fifteen) ſitting on the germen, uſually in more than a ſingle ſeries. STAMINA, numerous, ſhort, crooked filaments, and oblong antheræ affixed to their ſides. PISTILLUM, a large oval germen, no ſtyle, but an orbicular, plane target-ſhaped, cloſe-ſitting, crenated, permanent ſtigma. PERICARPIUM, a large oval, fleſhy, hardy, rude, multilocular bacca, crowned at top, and filled with many roundiſh ſeeds.

The moſt noted ſpecies are:

[1]NYMPHÆA *Lutea.*

*Yellow Nymphæa.*] Hath a large, knotty, ſpongy, deeply-ſtriking root; very large, heart-ſhaped, flat-expanded, entire leaves; and large yellow flowers, having a pentaphyllous calix, larger than the petals.

[2]NYMPHÆA *Alba.*

*White Nymphæa.*] Hath a large, knotty, ſpongy, deeply-penetrating root; large, heart-ſhaped, flat-expanded, entire leaves; and large, white, ſweet-ſcented flowers, having a quadrifid calix.

Both the ſpecies flower in June and July; the flowers are very large and conſpicuous, beautifully ſhewing themſelves on the ſurface of the water.

The plants are perennial in root, which ſtrikes deep into the ſand, gravel, or mud at the bottom of the water, from which ariſe their leaves and flowers annually, elevated to the top of the water, on long foot ſtalks, where they float, and juſt appear on the ſurface; the leaves generally coming up in April or May, and the flowers in June and July; ſucceeded by their large oval pericarpiums, filled with black ſhining ſeeds, ripening in the end of Auguſt, or in September; when being diſcharged from their cells, they ſink to the bottom of the water, where they germinate in ſpring following, and young plants ſoon appear at top; ſo that the plants thus multiplying each year, and the roots of each year's plants abiding and multiplying by offſets, they ſoon ſpread over a large ſpace of water.

*Their*

*Their Propagation.*

The propagation of theſe plants in gardens is by ſeed caſt into any piece of water where you intend they ſhall grow. To obtain the ſeeds, you muſt have recourſe in autumn to the places where the plants grow naturally, and watch the ripening of the ſeed-veſſels, gather a quantity juſt as they begin to open, which caſt into the water; the ſeeds will ſink, and the plants will appear at top in ſpring after, and ſome of which will probably flower the enſuing ſummer, though it is generally the ſecond year before they flower in perfection.

They being once thus raiſed, they will be of many years duration, and multiply greatly, ſo as to cover the whole ſurface of the water with their leaves and flowers in ſummer; ſo that only ſome ſmall pieces of water ſhould be allotted for this purpoſe.

---

# O.

OCYMUM, *(Baſilicum)* Baſil.

The plants are moſtly herbaceous, tender aromatic annuals, of branchy growth, proper for culinary and medical uſes, and for adorning the pleaſure garden; obtaining in ſtature, ſome half a yard, others little more than half a foot; cloſely garniſhed with oval and oblong ſimple leaves; and the ſtems and branches terminated by ſpikes of ſmall monopetalous ringent flowers.

Claſs and Order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, is monophyllous, bilabiated and permanent, the upper lip biſid, and the under acutely four-parted. COROLLA, is monopetalous, ringent, and inverted, with a ſhort ſpreading tube, and with the riſing lip broadeſt, cut into four obtuſe parts, the other is long, narrow, and undivided. STAMINA, two long and two ſhort declinated filaments, and half-moon-ſhaped antheræ. PISTILLUM, a four-parted germen, ſlender ſtyle, and biſid ſtigma. PERICARPIUM, none, four naked ſeeds lodged in the calix.

There are ſeven or eight ſpecies, but the moſt noted ſpecies in our gardens are the three following: each of which compriſes many varieties; all of which are remarkable for their ſtrong odoriferous ſcent, and are all of a tender quality, requiring to be raiſed and forwarded in a hot-bed.

[1]OCYMUM *Baſilicum.*

*Baſilicum, or Common Sweet Baſil.*] Riſes with an upright, ſquare, hairy ſtem, branching by pairs, from about ten inches to half a yard high; garniſhed with large, oval, ſmooth, oppoſite leaves; and the main ſtem and all the branches terminated by ſpikes of ſmall whitiſh flowers, having ciliated calixes.

*Varieties of this.*] Broad-leaved Baſilicum —narrow-leaved—fringed-leaved——fringed purple-leaved——curled-leaved——ſtudded-leaved——large purple-leaved——dark-green-leaved——tricolor-leaved——red-flowered——purple-flowered——long-ſpiked—ſhort-ſpiked, &c.

This ſpecies and varieties have a piercing aromatic ſcent, ſome like cloves, others like citron, and ſome like fennel; they are good for culinary uſes, in ſoup, &c. alſo for medical purpoſes; and the plants are employed for embelliſhing the pleaſure-garden.

[2]OCYMUM *Minimum.*

*Smalleſt Ocymum, commonly called Buſh Baſil.*] Riſes with a very ſhort ſtem, branching all around from the bottom, about ſix or eight inches high, forming a round buſhy head; ſmall oval very intire leaves, by pairs oppoſite; and the branches terminated by whorls of very ſmall whitiſh flowers.

*Varieties.*] With hoary leaves—dark-purple-leaved—variable-leaved.

This ſpecies and varieties are much cultivated about London, in pots to carry to market, for ornamenting balconies, windows, &c.

[3]OCYMUM *Tenuiflorum.*

*Small-flowered China Baſil.*] Riſes with an upright, taper, purpliſh ſtem, branching a foot

ſoot and a half high; oval-oblong, ſerrated leaves; and the main ſtem and branches terminated each by three ſlender ſpikes of exceedingly ſmall flowers, having heart-ſhaped, concave, reflexed bractæa.

*Varieties.*] With white flowers—purple flowers.

All theſe three ſpecies of *Ocymum*, and their reſpective varieties, are of the annual-tribe, riſing from ſeed in ſpring, flower in June and July, and ripen ſeeds in September, and totally periſh at the approach of winter; ſo that a freſh ſupply muſt be raiſed from ſeed annually in ſpring. See their *Propagation*.

The flowers are ſmall ringent hermaphrodites, collected into ſlender ſpikes of but little appearance.

All the ſpecies and varieties are accounted the ſtrongeſt aromatics in nature, and, for the general part, the odour is very agreeable; though to ſome perſons it is rather too powerful.

They are all exotics from India and other diſtant warm countries, and in theſe parts require to be raiſed and forwarded in hot-beds, as above obſerved, from March or April until towards the latter end of May or beginning of June, according to the temperature of the ſeaſon; then may be fully expoſed for the remainder of the ſummer.

With reſpect to their particular merit for our gardens, the common ſort *Ocymum Baſilicum*, and varieties, may be employed as culinary aromatics in the kitchen-garden; and ſome of all the three ſpecies, &c. as ornamental plants for the pleaſure-ground, both in the open compartments, and ſome in pots, in order for adorning court-yards, and to place in room-windows for their ſweet odour, particularly the Buſh-Baſil.

*Their Propagation, &c.*

The propagation of all the three ſpecies is by ſeed annually, in ſpring, in a hot-bed, and from which they are tranſplanted into the open ground, &c. in May or June.

March and beginning of April is the proper ſeaſon for ſowing them. Having a moderate hot-bed under a frame and glaſſes, earthed five or ſix inches depth of light mould; ſow the ſeed a quarter of an inch deep; they will come up in a few days: obſerving to indulge them with freſh air daily, and occaſional very moderate waterings; and when the plants are an inch or two high, prick ſome of them upon the ſame or another new hot-bed, three or four inches aſunder; or plant ſome ſingly in ſmall pots, and plunge them in the hot-bed, give water as ſoon as planted, together with occaſional ſhading from the ſun till freſh-rooted; continuing the admiſſion of freſh air daily, and repetitions of light refreſhments of water: in May harden them by degrees to the full air; and about the middle or latter end of the month, or beginning of June, in warm moiſt weather remove them into the open air, finally to remain, taking them up with balls about their roots, and plant ſome in the borders, others in larger pots, to move where occaſionally wanted; give water directly, and at times till they have taken freſh root, which they will ſoon effect, and arrive to their full growth in June and July, when they will flower, and ripen ſeeds in September.

To obtain more effectually ſome good ſeeds of thoſe plants in this country, it is adviſeable to move ſome in their pots in Auguſt into a glaſs-caſe, or garden-frame, to be ſheltered in cold weather, and from exceſſive wet; but admitting the free air in fine weather, and they will thus ripen ſeeds in tolerable plenty.

OCTANDRIA, the name of the eighth claſs: plants with hermaphrodite flowers, having eight ſtamina; and conſiſts of four orders, according to the number of ſtyles.

OENOTHERA, Tree-Primroſe.

This genus of plants conſiſts of hardy herbaceous biennials and perennials, and underſhrubby perennials; all of the flowery tribe, for the decoration of the pleaſure-garden; riſing with upright firm ſtems, from one foot to three or four high, in different ſorts; garniſhed with largiſh oval and ſpear-ſhaped leaves; and from the axillas on every ſide large, quadripetalous, primroſe ſhaped, yellow flowers, of conſiderable appearance; from June or July until October.

Claſs and order, *Octandria Monogynia*.

*Characters.*] CALIX, is monophyllous, long, tubular, divided at the brim into four acute reflexed ſegments, and is deciduous. COROLLA, heart-ſhaped plane petals, inſerted into the diviſions of the calix. STAMINA, eight awl-ſhaped, crooked filaments, terminated by oblong incumbent antheræ. PISTILLUM, a cylindric germen under the calix, filiforme ſtyle, and a thick, quadrifid, obtuſe, reflexed ſtigma. PERICARPIUM, a cylindric, tetragonous, quadrilocular, quadrivalved capſule, containing many ſmall angular ſeeds.

The moſt remarkable ſpecies of this genus in the Engliſh gardens are:

[1]OENOTHERA *Biennis.*

*Common Biennial Tree-Primroſe.*] Hath a long, thick, deeply-ſtriking root; crowned with many large, oval, ſpear-ſhaped, plane, ſpreading leaves; upright, thick, firm, rough, hairy ſtems, riſing three or four feet high; garniſhed with long, narrow, lanceolate, cloſe-ſitting leaves, irregularly; and at all the axillas, from the middle upwards, large bright-yellow flowers.

[2]OENOTHERA *Octovalvis.*

*Octovalved, Smooth, Biennial Tree-Primroſe.*] Hath upright, firm, ſomewhat hairy ſtems, riſing a yard high; oblong, ſpear-ſhaped, pointed, plane, ſmooth leaves; and at the axillas large bright yellow flowers.

[3]OENOTHERA *Fruticoſa.*

*Shrubby, Narrow-leaved, Perennial Tree-Primroſe.*] Hath long thick roots; upright, under-ſhrubby-like, red ſtems, two or three feet high; ſpear-ſhaped, lightly-indented leaves; and at the axillas pedunculated cluſters of yellow flowers; ſucceeded by pedicellated, acute-angled capſules.

[4]OENOTHERA *Pumila.*

*Low Perennial Tree-Primroſe.*] Hath fibrous roots; crowned with many oval, ſpear-ſhaped, cloſe-ſitting leaves; ſlender herbaceous ſtems, ten or twelve inches long; garniſhed with ſpear-ſhaped, blunt, ſmooth leaves, having very ſhort foot-ſtalks; and at the axillas ſmalliſh bright-yellow flowers; ſucceeded by acute-angled capſules.

All theſe plants flower very profuſely in June and July, coming out almoſt half the length of the ſtalks from the axillas; and as the ſtalk advances in ſtature, new flowers are produced, ſucceeding thoſe below; in which order the plants continue flowering from about Midſummer until October; each flower is moderately large and conſpicuous, conſiſting of four plane petals, which with the calix forms a very long tube below, and ſpreading above, generally expand moſt towards the evening; and are ſucceeded by plenty of ſeed in autumn for propagation.

Theſe plants are exotics from America, but are all very hardy, proſper in any common ſoil and ſituation, and have been long in the the Engliſh gardens, eſpecially the firſt three ſorts, but the *Oenothera Biennis* is the moſt commonly known.

The firſt and ſecond ſpecies are biennial, and the third and fourth are perennial in root.

They are proper to be employed as plants of ornament for embelliſhing the pleaſure-garden; they may be placed any where, and will effect a very agreeable variety three or four months with their plentiful blow of flowers.

The biennial kinds muſt be raiſed annually from ſeed, for they totally periſh ſoon after they have flowered.

But the perennials, once raiſed, continue for years by the root.

*Their Propagation.*

The propagation of all the ſorts is by ſeed, and the perennials alſo by parting the roots.

By Seed.—By this method both biennials and perennials may be raiſed plentifully in any bed or border of common earth. Sow the ſeed either in autumn or early in ſpring; the autumnal ſowings will riſe ſtrong betimes in the ſpring. In May or June, when the plants are two or three inches high, thin them where too cloſe; at the ſame time plant out a quantity in nurſery-rows ſix inches aſunder; give occaſional weeding, and plenty of water in dry weather; and in autumn they may be taken up with balls of earth about their roots, and planted where they are finally to remain.

By Parting the Roots.—The perennials being abiding, and multiplying by off-ſets of the roots; they may be propagated by dividing the roots into ſlips, in autumn or ſpring; each ſlip becomes a proper plant, producing flowers the following ſummer.

OFF-SETS, a ſort of ſuckers, or ſmall young plants, iſſuing from the ſides of the main roots of many ſorts of perennials, both bulbous, tuberous, and fibrous-rooted kinds, by which vaſt numbers of plants are propagated, as each Off-ſet becomes a proper plant, alike in every reſpect to the parent.

But Off-ſets are applicable moſt commonly to bulbous and tuberous-rooted perennials, ſuch as tulips, anemonies, &c. the Off-ſets of which are ſmall bulbs and tubers; and as moſt of the bulbous and tuberous-rooted tribe ſend forth plenty of Off-ſet roots from the ſides of the main ones annually, it is a certain, eaſy, and expeditious method of propagating all theſe kinds of plants, and each Off-ſet commences a new plant, producing ſtalks, leaves, flowers, fruit, &c. exactly like thoſe of the parent plant; ſo that having ſome roots of any particular approved ſpecies and varieties, you may increaſe them annually by the Off-ſets, and which, after having one or

two years growth, will flower, produce ſeed, and furniſh a ſupply of Off-ſets in their turn: all ſtill continuing the ſame as the mother-plant in every mode of growth.

Off-ſets, in the article of propagation, have this particular advantage over ſeedlings, that thoſe of the flowery kind will often flower in one year: whereas ſeedling plants of the bulbous kinds are frequently four, five, and ſometimes ſix or ſeven years before they flower in perfection; ſo that ſeedlings are principally to gain new varieties; and the roots of which furniſhing Off-ſets the varieties are increaſed.

As to the mode of ſeparating Off-ſets, it may be done in ſome ſorts every year, in others once in two or three years, according to the ſorts, and the increaſe of Off-ſets the main roots ſhall afford; which is always explained in the culture of the reſpective ſorts, under their proper genera.

The proper ſeaſon for ſeparating Off-ſets is, in the bulbous and many tuberous-rooted plants, chiefly ſummer and autumn, when they have done flowering, and the leaves decay, for at that period the roots of theſe ſorts having had their full growth for that ſeaſon, they aſſume an inactive ſtate of growth, not drawing any nouriſhment from the earth: they continuing at reſt, however, but a few weeks, attention muſt be had to take the opportunity of that interval, before they put out new fibres; which is the only proper period for moving all the bulbous kinds in particular, both to ſeparate the Off-ſets, and for tranſplanting the main roots, as for taking them up for keeping for a month or two, or longer. See BULBUS. Obſerving therefore the proper time, and having taken up the roots in dry weather if poſſible, let all the Off-ſets be ſeparated ſingly from the main bulb, &c. and plant the Off-ſets in nurſery-beds, in rows ſix inches aſunder, drilling them in with a hoe, two or three inches deep; and here let them remain a year or two, according to their ſize, to get ſtrength; then tranſplant them, at the proper ſeaſon, where they are to continue, managing them as other bulbous and tuberous-rooted plants. See BULBUS, RADIX, &c.

But with reſpect to Off ſets of fibrous-rooted perennials, you may either ſlip off the principal ones from the ſides of the main root, as they ſtand in the ground, or the root may be wholly taken up, and parted into as many ſlips as there are Off-ſets furniſhed with fibres. The proper ſeaſon for this is autumn, when their ſtalks decay, or early in ſpring before new ones begin to ſhoot forth; though ſome hardy ſorts may be ſlipped any time in open weather from September or October until February, planting them by dibble, the ſmaller Off-ſets or ſlips in nurſery-beds, in rows ſix or eight inches aſunder, to have a year's growth; and the larger ones may be planted at once where they are to remain, and they will flower the enſuing ſeaſon.

Several ſorts of ſhrubby perennials encreaſe by alſo Off-ſets at bottom; and the proper ſeaſon for taking them off is autumn and ſpring, or in hardy kinds it might be done any time in open weather, from October until March; planting them in nurſery-rows for a year or two, or till of proper ſize for the purpoſes for which they are deſigned.

Off-ſets of ſucculent plants ſhould generally be ſlipped off in ſummer; and previous to planting thoſe of the tender kinds, ſhould be laid on a dry ſhelf for ſome days, till the moiſture at bottom is dried up; then planted in pots of dry ſoil, and managed according to their different temperatures. See SUCCULENTÆ. No Off-ſets are ever to be expected from annual plants.

OLEA, Olive-tree.

This genus conſiſts of two ever-green exotic-trees for the green-houſe collection; generally aſſuming a ſhrubby-like growth, by riſing frequently with ſeveral ſtems from the bottom, branching laterally all the way; one ſort obtaining in ſtature twenty or thirty feet high, the other but ſix or ſeven feet; garniſhed with ſpear-ſhaped and oval ſtiff leaves, and cluſters of funnel-ſhaped flowers from the axillas; ſucceeded by that well-known oval fruit called Olives, in great eſtimation abroad for making oil, and for pickling, &c. but in this country the plants are retained principally for variety, as the fruit rarely attains due perfection.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX is ſmall, monophyllous, tubulous, quadridented, and deciduous. COROLLA, is monopetalous, infundibuliforme, with the top quadripartite and ſpreading. STAMINA, two ſhort filaments, and erect antheræ. PISTILLUM, a roundiſh germen, ſhort ſtyle, and thick bifid ſtigma. PERICARPIUM, a ſuboval, ſmooth, unilocular, drupaceous fruit, including an oblong-oval nut.

There are but two ſpecies, one of which, however, compriſes many varieties with reſpect to the fruit.

The ſpecies are;

[1]OLEA *Europæa.*

*European Common Olive tree.*] Riſes with upright ſolid ſtems, branching numerouſly on every ſide, twenty or thirty feet high; ſpear-ſhaped, ſtiff, oppoſite leaves, two or three inches long, and half an inch or more broad; and at the axillas ſmall cluſters of white flowers, ſucceeded by oval fruit.

This ſpecies is the principal ſort cultivated for its fruit; the varieties of which are numerous, varying in ſize, colour, and quality.

It is a native of the ſouthern warm parts of Europe, and is cultivated in great quantities in the ſouth of France, Italy, and Portugal, for the fruit to make the Olive-oil, which is in ſo great repute, and is tranſported to all parts, to the great advantage of thoſe countries where the trees grow in the open ground: the green fruit is alſo in much eſteem for pickling, of which we may ſee plenty in the ſhops.

[2]OLEA *Capenſis.*

*Cape Box-leaved Olive.*] Riſes with ſhrubby ſtems, branching numerouſly from the bottom, ſix or ſeven feet high; ſmall, oval, thick, ſtiff, ſhining leaves; and at the axillas ſmall cluſters of whitiſh flowers; ſucceeded by ſmall fruit of inferior value.

Theſe plants in this country muſt be kept principally in pots for moving to ſhelter of a green-houſe in winter; for they are too tender to proſper well in the open ground here; though ſometimes they are planted againſt a warm ſouth wall, and ſheltered occaſionally from froſt in winter, by mulching the roots, and matting their tops; whereby they may be preſerved, and will ſometimes produce fruit for pickling; a very ſevere winter, however, often kills or greatly injures their young branches; therefore let the principal part be potted in rich earth, and placed among the green-houſe ſhrubs, and managed as directed in the article GREEN-HOUSE PLANTS.

Theſe trees are often ſent over from Italy to the Italian warehouſes in London, along with orange-trees, &c. where pretty large plants may be purchaſed reaſonably, which ſhould be managed as directed for orange-trees that are imported from the ſame country. See CITRUS.

Their propagation here is commonly by layers.

The laying is performed on the young branches in ſpring; give plenty of water all ſummer, and they will ſometimes be rooted fit for potting-off by autumn; but ſometimes they require two ſummers to be rooted effectually: when, however, they are properly rooted, take them off early in autumn, and pot them ſeparately, give water, and place them in the ſhade till they have taken freſh root; and in October remove them into the green-houſe, &c.

Thoſe you intend to plant in the open-ground, as before ſuggeſted, ſhould be kept in pots, in order to have occaſional ſhelter of a garden-frame two or three years, till they have acquired ſome ſize, and are hardened to the full air; then tranſplant them into a warm border againſt a wall: mulch their roots in winter, and mat their tops in froſty weather.

ONONIS, Reſt-Harrow.

It conſiſts of hardy herbaceous perennials and annuals, and ſome ſhrubby plants; ſeveral of the former are troubleſome weeds in the fields, and ſome of the latter are proper for ornamenting the pleaſure-ground; moſt of the ſorts grow erect from about one foot to two or three high; garniſhed ſome with ſimple, others with trifoliate leaves; and papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is divided into five narrow arched ſegments, the lower ones bending under the carina. COROLLA, is papilionaceous, the ſtandard heart ſhaped, and depreſſed on the ſides, ſhort oval wings, and a pointed carina. STAMINA, ten diadelphous filaments, and ſimple antheræ. PISTILLUM, an oblong hairy germen, ſimple ſtyle, and obtuſe ſtigma. PERICARPIUM, a turgid, unilocular, bivalved pod, having kidney-ſhaped ſeeds.

There are many ſpecies, ſeveral of which are common weeds, often very troubleſome in the fields, their roots ſpreading widely around, and are ſo tough and ſtrong, as ſometimes to retard the progreſs of the huſbandman's harrow; whence originated the Engliſh name, Reſt harrow.

The moſt material ſpecies common to the gardens, are the following ſhrubby kinds.

[1]ONONOIS *Fruticoſa.*

*Shrubby Purple Reſt-harrow.*] Riſes with ſlender, ſhrubby, durable ſtems, branching numerouſly two or three feet high; ſpear-ſhaped, ſerrated, ternate leaves; and all the branches terminated by panicles of large red flowers, three on each pedunculi.

[2]ONONIS

[1]ONONIS *Tridentata*.

*Tridented Shrubby Reſt-harrow.*] Riſes with ſhrubby, ſlender ſtems, branching half a yard high; narrow, fleſhy, ternate leaves, tridented at the top; and the branches terminated by panicles of purple flowers, two on each pedunculi.

Both theſe ſhrubs flower very ornamentally in May or June, the flowers are papilionaceous or butterfly-ſhaped, large and conſpicuous, and are ſucceeded by ripe ſeeds in autumn.

The firſt ſort is very hardy, and proper for the ſhrubbery.

The ſecond requires ſhelter from froſt, ſo ſhould generally be kept in pots, in order for moving to a green-houſe or garden-frame in winter.

Their propagation is by ſeed, ſowed in April in a warm border, half an inch deep; or if thoſe of the ſecond ſort are ſowed in pots and plunged in a ſlender hot-bed, they will more certainly ſucceed; the plants will come up in May; give plenty of water all ſummer, and indulge the ſecond ſort with ſhelter in winter; in ſpring plant out both ſorts; the firſt in nurſery-rows a foot aſunder, to remain a year or two, when they will be fit for the ſhrubbery; and the ſecond plant in pots for moving to ſhelter in autumn.

OPHRYS, Twyblade, Bee-flower, &c.

This genus is compoſed of herbaceous, bulbo-fibrous-rooted perennials, moſtly inhabitants of our woods, paſtures, meadows, and ſome hilly grounds, but frequently employed in the pleaſure-garden for the ſingularity of their flowers; moſt of them are low plants, with erect annual ſtalks, from three or four inches to a foot high; ſome naked and ſome foliated, and terminated by ſpikes of ſmall pentapetalous nectariferous flowers, frequently of ſingular ſhapes, reſembling in ſome ſorts the figures of men, and various ſorts of inſects, as flies, bees, &c.

Claſs and order, *Gynandria Diandria.*

*Characters.*] CALIX, a vague ſpatha, protruding a ſimple ſpadix of flowers, without any perianthiums. COROLLA, five oblong, equal-aſcending petals, and a dependent long nectarium, keel-ſhaped behind. STAMINA, two very ſhort gynandrous filaments, and erect antheræ. PISTILLUM, an oblong contorted germen below the flower, a ſtyle adhering to the inner border of the nectarium, and obſolete ſtigma. PERICARPIUM, a trigonal, unilocular, trivalvular capſule, filled with numerous ſeeds like duſt.

The Engliſh name *Twyblade*, is from ſome of the ſpecies being remarkable for having only two leaves.

There are many ſpecies, but the moſt noted are the following, which are admitted into ſome pleaſure-gardens for variety.

[1]OPHRYS *Ovata.*

*Oval-leaved Ophrys, or Common Twyblade.*] Hath a bulboſe, fibrated root; crowned by two oval, broad, obtuſe, veined, oppoſite leaves; an erect, ſucculent, green ſtalk, ſix or eight inches high, naked above, and terminated by a looſe ſpike of greeniſh flowers, having the lip of the nectarium bifid.

The flowers of this ſpecies reſemble the figure of gnats.

[2]OPHRYS *Spiralis.*

*Spiral Orchis, or Triple Ladies Traces.*] Hath bulbous, oblong, aggregated roots; crowned by a cluſter of oval, pointed, ribbed leaves; erect ſimple ſtalks, half a foot high; terminated by long ſpikes of white, odoriferous flowers, hanging to one ſide, having the lip of the nectarium entire, and crenated.

[3]OPHRYS *Nidus-avis.*

*Nidus-avis, or Birds-neſt.*] Hath a bulboſe, fibrated, cluſtered root; upright, thick, ſucculent ſtalks, a foot high, ſheathed by the leaves, and terminated by looſe ſpikes of pale-brown flowers; having the lip of the nectarium bifid.

[4]OPHRYS *Anthropophora.*

*Man-ſhaped Ophrys, or Man Orchis.*] Hath a roundiſh bulboſe root; crowned with three or four oblong leaves; upright thick ſtalks, riſing a foot and a half high; adorned with narrow leaves, and terminate by looſe ſpikes of greeniſh flowers, repreſenting the figure of a naked man; the lip of the nectarium linear tripartite, with the middle ſegment longeſt and bifid.

*Variety.*] With browniſh flowers tinged with green.

[5]OPHRYS *Inſectifera.*

*Inſectiferous Ophrys, or Inſect Orchis.*] Hath two roundiſh bulbous roots; crowned with oblong leaves; erect leafy ſtalks, from ſix to ten or twelve inches high, terminated by ſpikes of inſect-ſhaped greeniſh flowers, having the lip of the nectarium almoſt five-lobed.

This wonderful ſpecies exhibit flowers in different varieties, that repreſent ſingular figures

gures of flies, bees, and other inſects; and are of different colours in the varieties.

*Varieties are.*] Fly-ſhaped *Ophrys*—great fly *Ophrys*—large green fly *Ophrys*—blue fly *Ophrys*—yellow fly *Ophrys*—bee *Ophrys*—large bee *Ophrys*—black bee *Ophrys*—green winged bee *Ophrys*—beetle *Ophrys*—ſpider *Ophrys*.

6 OPHRYS *Monorchis*.

*Monorchis, or Muſky Ophrys.*] Hath a roundiſh bulboſe root; crowned with three or four oblong leaves; an erect naked ſtalk, ſix inches high; terminated by a looſe ſpike of yellowiſh, muſky-ſcented flowers.

All theſe ſix ſpecies of *Ophrys* flower in ſummer, at different times in different ſorts, from May until July; and in moſt of the ſorts exhibit a ſingularly curious appearance.

The plants are all perennial in root, which are of the bulbous fleſhy kind, from which the flower-ſtalks riſe annually in ſpring, and decay in autumn; at which period is the proper time for removing the roots from one place to another.

They all grow wild in England, &c. are reſidents of woods, bogs, marſhy grounds, ſterile paſtures, chalky ſoils, and the like places, where they flouriſh and diſplay their ſingular flowers in great abundance, from which places they are introduced into gardens for variety; and having procured ſome plants at the proper ſeaſon, and planted them in ſoils and ſituations ſomewhat ſimilar to that where they naturally grow, the roots will abide for ſeveral years, and flower annually.

They may be eaſily obtained from the places where they naturally grow, and are kept at moſt of the public nurſeries for ſale.

The proper ſeaſon for removing them is in ſummer when the ſtalks decay; therefore repairing either to the places of their growth, when in full bloom, or to the nurſeries, mark a quantity of the beſt plants with ſticks; and when the ſtalks and leaves aſſume a decayed ſtate, proceed to dig up the roots, and bring them into the garden and plant them directly.

It is proper to ſuit the ſituation and ſoil of the different ſorts as near as poſſible; thoſe of the woods place in ſhady moiſt borders, or in ſhrubbery quarters among trees; thoſe of boggy or marſhy ground, plant in the moiſteſt parts of the garden; and thoſe found on dry ſterile plains or commons, ſhould have a dry open expoſure.

Having planted them, let them remain conſtantly undiſturbed, unleſs particularly wanted to be removed from one place to another, for the leſs they are diſturbed the better they will flower.

As to their propagation, it may be tried by ſeed in a ſhady border, as ſoon as it is ripe; likewiſe by off ſets from the root, though they multiply ſparingly in gardens; however roots of ſome ſtanding may be examined at the proper ſeaſon, and any off-ſets ſeparated and planted directly in the proper places.

ORCHARD, a garden-department, conſigned intirely to the growth of ſtandard fruit-trees, for furniſhing a large ſupply of the moſt uſeful kinds of fruit.

In the orchard you may have as ſtandards all ſorts of apple-trees, moſt ſorts of pears and plums, and all ſorts of cherries; which four ſpecies are the capital Orchard-fruits: each of which compriſe numerous valuable varieties; but to have a complete Orchard, may alſo have quinces, medlars, mulberries, ſervice-trees, filberts, Spaniſh nuts, berberries; likewiſe walnuts and cheſnuts; which two latter are particularly applicable for the boundaries of Orchards, to ſcreen the other trees from the inſults of impetuous winds and cold blaſts: all of which trees being arranged in rows from twenty to thirty feet diſtance, as hereafter directed.

But ſometimes Orchards conſiſt intirely of apple-trees, particularly in the cyder-making countries, where they are cultivated in very great quantities in large fields, and in hedge-rows, for the fruit to make cyder for public ſupply.

And ſometimes whole Orchards of very conſiderable extent are intirely of cherry-trees; but in this caſe, it is when the fruit is deſigned for ſale in ſome great city, as London, &c. for the ſupply of which city, great numbers of large Cherry-Orchards are in ſome of the adjacent counties, but more particularly in Kent, which is famous for very extenſive Cherry-Orchards; many of which are entirely of that ſort called Kentiſh cherry, as being generally a great bearer; others are ſtored with all the principal ſorts of cultivated cherries, from the earlieſt to the lateſt kinds. See PRUNUS *Ceraſus*.

A general Orchard, however, compoſed of all the before mentioned fruit-trees, ſhould conſiſt of a double portion of apple-trees or more, becauſe they are conſiderably the moſt uſeful fruit, and may be continued for uſe the year round.

The

The utility of a general Orchard, both for private uſe and for profit, ſtored with the various ſorts of fruit-trees, muſt be very great, as well as afford infinite pleaſure from the delightful appearance it makes from early ſpring till late in autumn: in ſpring the various trees in bloſſom are highly ornamental; in ſummer, the pleaſure is heightened by obſerving the various fruits advancing to perfection; and as the ſeaſon advances, the mature growth of the various ſorts arriving to perfection in regular ſucceſſion from May or June until the end of October, muſt afford exceeding delight, as well as great profit.

*Of the proper Extent, Situation, and Soil, for this Department.*

As to the proper extent of ground for an Orchard, this muſt be proportioned, in ſome meaſure to the extent of land you have to work on, and the quantity of fruit required either for private uſe, or for public ſupply: ſo that an orchard may be from half an acre to twenty or more extent.

With reſpect to the ſituation and aſpect for an Orchard, we may obſerve very thriving Orchards both in low and high ſituations, and on declivities and plains, in various aſpects or expoſures, provided the natural ſoil is good: I ſhould, however, avoid very low damp ſituations as much as the nature of the place will admit; for in very wet ſoils no fruit-trees will proſper, nor the fruit be fine; but a moderately low ſituation, free from copious wet, may be more eligible than an elevated ground, as being leſs expoſed to tempeſtuous winds; though a ſituation having a ſmall declivity is very deſirable, eſpecially if its aſpect incline towards the eaſt, ſouth-eaſt, or ſoutherly, which are rather more eligible than a weſterly aſpect; but a north aſpect is the worſt of all for an Orchard, unleſs particularly compenſated by the peculiar temperament or good quality of the ſoil: I would, however, remark, for the advantage of thoſe that are not accommodated with choice of ſituation and aſpect, that they need not be under any great anxiety, provided as above ſaid, if the ſoil is but ſuitable; only obſerving, if poſſible, to abandon very low damp ſituations, for the reaſon before given.

And as for ſoil, any common field or paſture that produces good crops of corn, graſs, or kitchen-garden vegetables, is ſuitable for an Orchard; if it ſhould prove of a loamy nature, it will be a particular advantage: any ſoil, however, of a good quality, not too light and dry, or too heavy, ſtubborn, or wet, but of a medium nature of a ſoft pliant temperature, not leſs than one ſpade deep of good ſtaple, will be proper for this purpoſe.

Where, however, the ſoil is naturally defective, the defects muſt be rectified as well as poſſible, by the application of proper manures, and compoſts prepared as directed under thoſe articles, and applied either to the whole ground, if but of moderate extent, or to the places where each tree is to ſtand, for a ſpace of eight or ten feet circumference, working it up with the natural ſoil of the place.

This, however, in extenſive Orchards, would be a very chargeable operation; therefore thoſe who are at liberty to chuſe, ſhould have particular regard to the fixing upon a proper ſpot, where but little or no foreign aid is requiſite.

*Preparation of the Ground.*

The preparation of the ground for the reception of the trees, is by trenching, or if for very conſiderable Orchards, by deep ploughing; but trench-digging, one or two ſpades, as the ſoil will admit, is the moſt eligible, either wholly, or only for the preſent, in the places where the lines of trees are to ſtand, a ſpace of ſix or eight feet wide, all the way in each row, eſpecially if it be graſs-ground, and intended to be kept in ſward; or if any under-crops are deſigned to be raiſed, the ground may be wholly trenched at firſt; but as to this you may ſuit your convenience, obſerving in either caſe to trench the ground in the uſual way to the depth of the natural ſoil; and if in graſs, turn the ſward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.

In planting Orchards, however, on graſs-ground, ſome only dig pits for each tree, capacious enough for the reception of the roots, looſening the bottom well, without the labour of digging any other part of the ground: where the ground, however, is trenched either wholly, or ſome conſiderable width along the place of each row of trees, it will conſequently prove of greater advantage in promoting their free growth.

The ground muſt be fenced ſecurely againſt cattle, &c. either with a good ditch and

hedge, or with a paling-fence, as may be moſt convenient. See HEDGES.

*Method of planting the Trees.*

The beſt ſeaſon for planting all the ſorts of fruit-trees is autumn, ſoon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.

All the ſorts of fruit-trees proper for this department, if not furniſhed with them in your own nurſery, may be had very reaſonable at all the public nurſery-grounds; obſerving to chuſe them principally full ſtandards, with ſtreight clean ſtems, ſix feet high, eſpecially the apples, pears, plums, cherries, and other tree kinds, each with a branchy well-formed head, of from two or three to four or five years growth; and let ſeveral varieties of each particular ſpecies be choſen, that ripen their fruit at different times, from the earlieſt to the lateſt, according to the nature of the different ſorts, that there may be a ſufficient ſupply of every ſort regularly during their proper ſeaſon; and of apples and pears in particular, chuſe a much greater quantity of the autumnal and late-ripening kinds, than the early ſorts; but moſt of all of apples: for the ſummer-ripening fruit is but of ſhort duration, only proper for temporary ſervice; but the later-ripening kinds keep ſound ſome conſiderable time for autumnal uſe; and the lateſt ſorts that ripen in October, continue in perfection for various uſes all winter, and ſeveral ſorts until the ſeaſon of apples come again. See the liſt of the different ſorts of fruit in this work, under their reſpective genera.

Having made choice of the proper ſorts, and marked them, let them be taken up with the utmoſt care, ſo as to preſerve all their roots as entire as poſſible; and when taken up, prune off any broken or bruiſed parts of the roots, and juſt tip the ends of the principal roots in general with the knife, on the under ſide, with a kind of ſlope outward.

If the trees have been already headed, or ſo trained as to have branched out into regular ſhoots to form each a proper head, they muſt be planted with the ſaid heads entire, only retrenching or ſhortening any irregular or ill-placed ſhoot that take an aukward direction, or grow acroſs its neighbours, or ſuch that may run conſiderably longer than all the reſt, &c. as obſerved under the reſpective articles in training them for ſtandards, alſo in the article STANDARD-TREES.

The arrangement of the trees in the Orchard muſt be in rows, each kind ſeparate, at diſtances according to the nature of growth of the different ſorts; but for the larger growing kinds, ſuch as apples, pears, plums, cherries, &c. they ſhould ſtand from twenty-five to thirty or forty feet every way aſunder, though twenty-five or thirty feet at moſt is a reaſonable diſtance for all theſe kinds.

Each ſpecies and its varieties ſhould generally be in rows by themſelves, the better to ſuit their reſpective modes of growth: tho' for variety may have ſome rows of apples and pears arranged alternately; as alſo plums and cherries; and towards the boundaries may may have ranges of leſſer growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut-trees, and ſome cheſnuts, ſet pretty cloſe to defend the other trees from violent winds.

According to the above diſtances proceed to ſtake out the ground, for making the holes for the reception of the trees; which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the ſun's influence more effectually.

But in planting very extenſive Orchards, ſome divide the ground into large ſquares or quarters of different dimenſions, with intervals of fifty feet wide between: ſerving both as walks, and for admitting a greater currency of air: in different quarters planting different ſorts of fruit, as apples in one, pears in another, and plums and cherries in others, &c. and thus it may be repeated to as many quarters, for each ſpecies and its varieties, as may be convenient.

As to the mode of planting the trees, it is the ſame as directed under their ſeveral articles, and the article PLANTING. A wide hole muſt be dug for each tree, capacious enough to receive all the roots freely every way without touching the ſides. When the holes are all ready, proceed to planting, one tree to each hole, a perſon holding the ſtem erect, whilſt another trims in the earth, previouſly breaking it ſmall; and caſt it in equally about all the roots, frequently ſhaking the tree to cauſe the mould to ſettle in cloſe about all the ſmaller roots and fibres, and ſo as to raiſe the tree gradually up, that the crown of the roots may be but two or three inches below

low the general ſurface; and when the hole is filled up, tread it gently, firſt round the outſide, then near the ſtem of the tree; forming the ſurface a little hollow; and then if on the top of all is laid ſome inverted turf to the width of the holes, forming it with a ſort of circular bank, three or four inches high, it will ſupport the tree, and guard the roots from drying winds, and the ſummer's drought: obſerving that each tree ſtands perfectly upright, and that they range exactly in their proper rows.

If the orchard is much expoſed to the winds, it may be proper to ſtake the new-planted trees to ſupport them in their proper poſition, and ſecure them from being rocked to and fro by the wind, which would greatly retard their rooting afreſh; placing one or two ſtrong tall ſtakes to each tree; but the moſt effectual method is to have three ſtakes to each, placed in a triangle, meeting at top near the head of the tree, wrapping a hay-band round that part of the ſtem, to prevent its being barked by the ſtakes or tying; then tie the ſtakes at top cloſe to the tree with ſome proper bandage, bringing it cloſe about the ſtem and ſtakes together, over the hay-wrapping, in a proper manner to ſecure the tree firmly in an erect poſture.

The ground of the Orchard, between the rows of trees, is very commonly laid down in graſs, as being the moſt convenient for admitting of coming readily at the trees at all times to gather the fruit: but if thought proper, it may be employed for ſome years either wholly, or in part, for the produce of kitchen vegetables, or for the growth of corn, turneps, potatoes, &c. being careful in digging or ploughing the ground for the reception of theſe crops, not to go too near to diſturb the roots of the trees; likewiſe not to have any ſtrong growing plants within three feet of each ſide of the rows of trees: however, after the trees are advanced in growth, and begin to bear any thing conſiderably, it may be more eligible to lay the ground down intirely in graſs, as it will be then more in character of an orchard, and be more convenient for gathering the fruit, and doing any neceſſary work to the trees; but in any of theſe ways, every one may ſuit their inclination or convenience.

If, however, it is laid down in graſs, no cattle ſhould be turned in to graze at large, unleſs the ſtems of each tree is previouſly well ſecured with poſts and railing, and wattled with thorn-buſhes, eſpecially in young Orchards, otherwiſe they will bark the trees, to their very great injury, nor ſhould large cattle be turned in to Orchards, where the branches of the trees are yet low and within their reach.

*General Culture.*

With regard to the general culture of Orchard fruit-trees, obſerve for one thing, that as being ſtandards, their heads ſhould generally be permitted to branch out nearly in their own natural manner, with the branches at full length, without ſhortening, only on particular occaſions, and they will gradually form themſelves into large branchy heads, and all the branches ſoon aſſume a bearing ſtate; very little pruning of any ſort being required to ſtandard fruit-trees, except in particular caſes, as above hinted, of ſuperfluous or very irregular growths; as for example, all ſuckers ariſing from tke root, muſt conſtantly be taken off cloſe; likewiſe diveſt the ſtems of all ſide-branches coming out below the head; and all luxuriant ſhoots ariſing in the heart or middle of the tree, or in any part where they appear too much crowded, ſhould be pruned off cloſe: if any particular branch of the head ſhould become of very long ſtraggling growth, extending conſiderably beyond all the reſt, it may be ſhortened as you ſhall ſee proper, down to ſome young ſhoot, or lower branch it ſupports, ſo as to preſerve a little regularity; likewiſe any branch that takes an irregular direction acroſs the others, or any other aukward growth, ſuch may either be ſhortened down to any lower branch it ſupports that is of a regular growth, or intirely retrenched as it may ſeem proper to keep up ſome uniformity in the head; and if the head in general becomes at any time over-crowded with branches, thin out the worſt and moſt irregular growers of the ſuperfluity: all dead wood and cankered parts ſhould alſo be cut off to the live wood.

But remarking, that, except in the above caſes, the branches in general of ſtandard fruit-trees, in every ſtage of growth, ſhould be ſuffered to ſhoot forth, both in length and branch, laterally in their own way; for as moſt of the ſorts firſt form their fruit-buds, or ſpurs, near the extremity of the branches or ſhoots, if pruning their ends was practiſed, it would not only be cutting off the parts where the fruit would have been firſt produced, but would force out a number of lateral uſeleſs ſhoots, and crowd the tree with ſuperfluous or unneceſſary wood, and greatly retard the

branches from forming the above fruit-ſpurs or buds for bearing; and unleſs theſe are formed in plenty, none of the principal tree-kinds can ever produce any tolerable crops of fruit; but the trees being ſuffered to take their natural growth, according to the above rules, all the branches and ſhoots will gradually form fruit-ſpurs towards their extreme parts, at almoſt every eye or bud.

By the above hints it is obvious that ſtandard fruit trees require but very little culture in reſpect to pruning; and the leſs they are pruned, except in the before mentioned caſes, the better they will bear.

Beſides, to attempt at any regular pruning of Orchard or other ſtandard fruit-trees, would prove a very tedious as well as unneceſſary work.

When neceſſary, however, to prune any of theſe trees occaſionally in the above caſes, obſerve that the proper ſeaſon for that work is any time from the fall of the leaf until March. Likewiſe obſerve in performing that operation, that ſuch branches as require retrenching ſhould be cut off quite cloſe either to their origin, if neceſſary, or cloſe to any more convenient branch it may ſupport, not leaving any ſtump, and make the cut as even and ſmooth as poſſible.

Orchard-trees are ſometimes greatly infeſted with moſs growing all over their branches, but more particularly thoſe trees which are ſituated in very damp ſoils; alſo often in old Orchards where the trees ſtand ſo cloſe as to crowd one another ſo conſiderably as to exclude the free air: in which caſe of moſſineſs, the trees commonly aſſume a ſtunted unkindly growth, producing but indifferent crops, and the fruit often ſmall and ill-flavoured. The only remedy for this diſaſter, is, to thin out ſome of the branches where thickeſt, to admit the ſun and air more freely, and ſcrape the moſs off from the remainder, with an inſtrument directed below; but where the trees thus infeſted ſtand very cloſe to one another, ſome of them ſhould be cut down to admit a larger portion of air, and the ſun's heat and light; and for the ſame reaſon thin the branches of the remaining trees; then clear the branches in general from the groſſeſt of the moſs; for which purpoſe you ſhould be provided with ſome iron ſcrapers hollowed on the edge, and of three different ſizes to ſuit the different branches, having the edges a little blunted; and with theſe tools ſcrape off the moſs from all the principal branches at leaſt, and of as many of the ſmaller ones as your time will permit, for it is tedious work where there are many trees: after this, if the ground of the Orchard, either wholly or but ten or twelve feet width along each row of trees, is dug or deeply ploughed, it will give new vigour to the roots, and which together with the thinning of the trees to admit the ſun and air freely, and the principal branches being diveſted of the moſs, you will find them ſhoot at top with freſh vigour, and the quantity, ſize, and quality of the fruit be greatly augmented in a year or two.

For farther remarks reſpecting the particular culture of each different ſpecies, and its varieties, cultivated as Orchard-trees, ſee the ſeveral articles under their reſpective genera.

And with reſpect to the times of ripening of the different fruits, time and method of gathering the various kinds, and of preſerving thoſe of the keeping ſorts, it is properly exhibited in all the different articles under their proper heads.

ORCHIS, *(Orchis)* Fool-ſtones.

The plants are hardy, herbaceous, bulbous-rooted, flowery perennials, moſtly natives of our meadows, paſtures, woods, and uncultivated places, and which, like the ſpecies of *Ophrys*, having great ſingularity in their flowers, are admitted into pleaſure-gardens for variety; moſt of them have roots compoſed of two teſticulated bulbs, ſending up annually one or more flower-ſtalks, from about five or ſix inches to half a yard high; terminated by ſpikes of pentapetalous nectariferous flowers of various odd figures in different ſpecies, reſembling ſometimes a naked man, ſometimes a butterfly, gnat, and other ſtrange ſhapes.

Claſs and order, *Gynandria Diandria.*

*Characters.*] CALIX, a vague ſpatha, protruding a ſimple ſpadix of flowers, without perianthiums. COROLLA, five petals, three of them exterior and two interior, riſe upward and meet; and a monophyllous nectarium between the diviſions of the petals, having a ſhort upper lip; the under large, broad, and ſpreading; with the tube nutant and horn-ſhaped. STAMINA, two ſhort gynandrous filaments, and oval erect antheræ. PISTILLUM, an oblong contorted germen below the flower, very ſhort ſtyle, and a compreſſed obtuſe ſtigma. PERICARPIUM, an oblong, three-keeled, trivalvate, unilocular capſule, filled with numerous ſeeds.

The roots of moſt of the ſpecies of this genus being compoſed of two oblong fleſhy bulbs joined together, bearing an obvious reſemblance to the ſcrotum, or teſticuli of animals,

mals, it derives both its generic name, and the Engliſh appellation, Fool-ſtones, &c. Moſt of the ſpecies are celebrated provocatives, which reſtorative quality is chiefly poſſeſſed by the roots; of which alſo by a late diſcovery may be prepared a powder for making ſalep, nearly reſembling that from Turkey, the alimentary virtues of which are well known.

There are numerous ſpecies, but the moſt remarkable are the following:

[1]ORCHIS *Maſcula.*

*Male Fool-ſtones.*] Hath a root compoſed of two bulbs; crowned with oblong, broad, ſpotted leaves; upright flower-ſtalks, a foot high; garniſhed with one or two narrow amplexicaule leaves; and terminated by a long ſpike of reddiſh-purple flowers, having the petals reflexed backward; a quadrilobed crenated lip to the nectarium, and an obtuſe horn.

The flowers of this ſpecies poſſeſs a very agreeable odour.

It grows wild in meadows and paſtures.

[2]ORCHIS *Morio.*

*Morio, or Female Orchis.*] Hath a double bulbous root; crowned with oblong, ribbed, ſpreading leaves; erect flower-ſtalks, eight or ten inches high; garniſhed with a few amplexicaule leaves; and terminated by a ſhort looſe ſpike of flowers, having connivent petals; a quadrifid crenated lip to the nectarium, and an obtuſe horn.

*Varieties.*] Purple-flowered—red-flowered—violet-coloured——fleſh-coloured——and white-flowered.

It grows naturally in woods and rough places.

[3]ORCHIS *Militaris.*

*Military, or Man Orchis.*] Hath a double bulbous root; crowned with oblong amplexicaule leaves; erect flower-ſtalks, eight or ten inches high; terminated by a looſe ſpike of aſh-coloured and reddiſh flowers, having confluent petals; a quinquefid, rough, ſpotted lip to the nectarium, and an obtuſe horn.

The ſtructure of the flowers exhibit the figure of a naked man; and are often of different colours in the ſame flower, as aſh-colour, red, brown, and dark-ſtriped.

It grows in chalky ſoils, and paſture grounds.

[4]ORCHIS *Bifolia.*

*Bifoliated, or Two-leaved Common Butterfly-Orchis.*] Hath a double bulbous root; crowned with uſually two, or from two to four oblong leaves; upright flower-ſtalks, eight or ten inches high, garniſhed with a few ſmall amplexicaule leaves; and terminated by a looſe ſpike of butterfly-ſhaped white flowers, with ſpreading petals; a ſpear-ſhaped entire lip to the nectarium, and a very long horn.

This is a reſident of rough paſtures, and buſhy places.

[5]ORCHIS *Latifolia.*

*Broad-leaved Handed Orchis.*] Hath a double, bulbous, ſub-palmated or almoſt hand-ſhaped, ſtreight root; upright thick flower-ſtalks, ten or twelve inches high; garniſhed the whole length with long, broad, amplexicaule leaves; and terminated by a ſhort cloſe ſpike of red purple-ſpotted flowers, having a conical-ſhaped horn to the nectari; a trilobate lip reflexed on the ſides, and with bractæa longer than the flowers.

It grows naturally in meadows and paſtures.

[6]ORCHIS *Maculata.*

*Maculated, or Spotted, Handed Orchis.*] Hath a double, bulbous, palmated root, with the diviſions ſpreading wide aſunder; upright, thick, ſpotted flower-ſtalks, a foot or more high, fully garniſhed with long, narrow, dark-ſpotted amplexicaule leaves; and terminated by a cloſe ſpike of flowers, having the hinder part of the petals ſpreading; a plane, trifid, ſpotted lip to the nectari, and the horn ſhorter than the germen.

*Varieties.*] Purple-flowered——deep purple—roſe-coloured—and white flowered.

They are reſidents of moiſt meadows and paſtures.

[7]ORCHIS *Abortiva.*

*Abortive Orchis, or Purple Bird's-Neſt.*] Hath bulbous roots cluſtered together; upright, thick, purple ſtalks, a foot and a half high; ſheathed with narrow purpliſh leaves; and terminated by a looſe thyrſe of purple flowers, having the lip of the nectarium oval and entire.

It grows wild in meadows and ſhady places.

[8]ORCHIS *Conopſea.*

*Gnat Orchis.*] Hath a bulbous palmated root; crowned with long narrow ſpotleſs leaves; upright ſtalks, a foot high; ſheathed with ſhort narrow leaves; and terminated by a long ſpike of red flowers, having two of the petals ſpreading; a triſid-lipped nectarium, and a briſtly horn longer than the germen.

It is an inhabitant of meadows and upland paſtures.

All theſe *Orchiſes* are very hardy perennials, with bulbous fleſhy roots; durable by the root, but annual in leaves and flower-ſtalks;

moſt of them are natives of England, growing wild, ſome ſorts in meadows, woods, and paſtures; others in dry ſterile uncultivated ſoils; but for the ſingularity and beauty of the flowers, are introduced into many curious gardens to encreaſe the variety in the herbaceous collection, and may be procured from the places where they grow ſpontaneouſly, which is in many parts of the kingdom: ſeveral of the ſorts are alſo retained in the public nurſeries for ſale.

They flower in May, June, and July, but principally in June; their mode of flowering is univerſally in ſpikes, many flowers in each ſpike; and each flower is compoſed of five petals in two ſeries, and a nectarium. See the *Characters*.

A few of theſe ſingular plants may be diſpoſed in different parts of the pleaſure-garden, in any of the compartments where they may be the moſt conſpicuous; they, however, are the moſt proſperous in a ſituation and ſoil ſomewhat ſimilar to that where they naturally grow.

The ſeaſon for removing them is in ſummer, after they have done flowering, when their leaves and ſtalks decay: mark this particularly, and it is adviſeable to plant them again as ſoon as poſſible after removal; planting them three inches deep; and let them remain undiſturbed ſeveral years, for the leſs they are removed the ſtronger they will flower.

We formerly obſerved, that the roots of theſe plants were poſſeſſed of very nutritious virtues, particularly for making ſalep. By a late diſcovery communicated to the Royal Society, it appears that the root of the ORCHIS *Maſcula*, with moſt of the other Orchis-roots of our own country, may be prepared a powder to reſemble the *Salep* that comes from Turkey; the alimentary virtues of which, as before obſerved, are well known, as well as its exhorbitant high price, which confines it in a great degree only to perſons of affluent circumſtances; but as many of the ſpecies of *Orchis* are indigenous plants of Britain, growing ſpontaneouſly in moſt parts of the kingdom, and as they flouriſh in almoſt any dry barren ſoil, by a little culture, all ranks of people might in a ſhort time be accommodated with this nutritious vegetable for making ſalep powder; and for encouraging its propagation, the Society of Arts and Sciences in London have lately offered premiums.

Their propagation may be tried both by ſeed and by off-ſets of the roots.

By Seed.—This muſt be very carefully collected in the places where the plants grow naturally; and ſow it directly in the garden, in a border of light earth, and rake it in with a light and even hand; and if it grows freely, the plants may either be thined and remain where ſowed, or when a year or two old, may plant them out in rows a foot aſunder.

By Roots.—As before obſerved, the roots may be procured in plenty from the places of their growth, taking them up when their leaves decay in ſummer, and plant them directly where they are to remain, three inches deep: here they will probably increaſe by off-ſets, like other bulbous roots, which may be taken up every two or three years, at the proper ſeaſon as above, in order to ſeparate the off-ſets, planting the whole again as ſoon as poſſible, placing the off-ſets in beds by themſelves.

When deſigned to cultivate theſe plants for uſe, the roots ſhould be depoſited in beds, in rows ten or twelve inches aſunder, and the depth as above.

ORDO, an Order: the firſt ſub-diviſion of a claſs in the ſexual arrangement of plants; and each claſs is ſubdivided into Orders, or ſecondary diviſions, founded principally on the number of ſtyles or female organs, and ſome other ſtriking part of the fructification of flowers; and the Orders are divided into genera, &c.

Each Order is diſtinguiſhed by a proper name, according to the number of ſtyles, &c. for example, when one ſtyle, it is termed *Monogynia*; two ſtyles, *Digynia*; three, *Trigynia*; four, *Tetragynia*; five, *Pentagynia*; many ſtyles, *Polygynia*, &c. which names of the Orders are always ſubjoined to that of their reſpective claſſes, as well in all the different genera deſcribed in this work, immediately preceding the *Characters*, as under the article CLASSIS, which ſee.

The names of the Orders are often the ſame in different claſſes, becauſe the ſame idea predominates in their inſtitution. See CHARACTERS, CLASSIS, and GENUS.

ORIGANUM, Origany, or Marjoram.

This genus furniſhes ſome under-ſhrubby perennials, and an herbaceous annual; all fine aromatics, ſome for the kitchen-garden, pleaſure-ground, and green-houſe; riſing with upright branchy ſtems, from ſix or eight inches to two feet high, garniſhed with oval and roundiſh leaves, and ſmall monopetalous

talous ringent flowers collected into ſpikes and heads, at the axillas and tops of the ſtalks.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, an involucrum compoſed of oval, coloured leaves, placed imbricatim, with unequal perianthiums. COROLLA, one ringent petal, with a cylindric compreſſed tube, and the upper lip plane and emarginated, the lower one trifid. STAMINA, two long and two ſhort filaments, and ſimple antheræ. PISTILLUM, a quadrifid germen, ſlender ſtyle, and bifid ſtigma. PERICARPIUM, none; four naked ſeeds, lodged in the boſom of the calix.

The principal ſpecies of our gardens, are two hardy perennials, and an annual for the open ground, and five perennials for the green-houſe.

*Hardy Perennial Kinds.*

[1]ORIGANUM *Vulgare*

*Common Origany, or Wild Pot Marjoram.*] Hath a fibrey perennial root; many upright, ſquare, ligneous ſtems, branching half a yard or two feet high; cloſely garniſhed with oval, almoſt cloſe-ſitting, oppoſite leaves, with ſmaller ones from the axillas; and at the ſides and ends of the branches, roundiſh, paniculated, conglomorated ſpikes of ſmall pale-red flowers, having oval bractæa longer than the calix.

*Varieties.*] Purple-flowered—white-flowered—variegated-leaved.

[2]ORIGANUM *Heracleoticum.*

*Heracleotic Origany, or Winter Sweet Marjoram.*] Hath a fibrated perennial root; upright, four-cornered, purpleiſh ſtems, branching half a yard high; garniſhed with oval, obtuſe, hairy, oppoſite leaves, on ſhort foot-ſtalk; and at the axillas of the ſtems, long aggregate ſpikes of ſmall white flowers, having the bractæa as long as the calix.

*Variety.*] Variegated-leaved.

Both the above hardy perennial *Origanums*, are finely-ſcented aromatics, excellent for culinary purpoſes, particularly for broths, ſoups, &c they have likewiſe merit for medical uſes, and for giving fragrance to ointments; ſo that the plants are proper both for kitchen and phyſic-gardens, and may alſo be employed in the pleaſure-ground as plants of variety.

*Annual Kind.*

[3]ORIGANUM *Marjorana.*

*Marjorana, or Annual Sweet Marjoram.*] Hath a fibrous annual root; upright branchy ſtems, riſing a foot or fifteen inches high; ſmall, oval, obtuſe, hoary leaves; and the ſtem and branches terminated by roundiſh, compact, downy ſpikes of ſmall white flowers.

This annual is an aromatic of the higheſt fragrance, is admirable for kitchen uſe, and is excellent for noſegays; ſo is proper both for the kitchen and pleaſure-garden, but more particularly the former.

It is often called knotted Marjoram, from the flowers growing in cloſe knotted-like heads.

*Green-houſe Kinds.*

The following moſtly aſſume an under-ſhrubby growth; frequently with abiding ſtalks, if they have ſhelter here in winter.

[4]ORIGANUM *Dictamnus.*

*Dictamnus, or Dittany of Crete.*] Riſes with ſlender, hairy, purple ſtalks, branching by pairs eight or ten inches high; garniſhed with round thick leaves, the under ones woolly; and the branches terminated by nodding ſpikes of purple flowers.

This ſpecies is a very ſtrong aromatic.

[5]ORIGANUM *Sipyleum.*

*Origanum of Mount Sipylus.*] Riſes with upright, four-cornered, ſmooth, purpleiſh ſtalks, branching by pairs near two feet high; oval ſmooth leaves; and all the branches terminated by oblong nodding ſpikes of purpleiſh flowers.

[6]ORIGANUM *Creticum.*

*Cretan Origany, or Marjoram.*] Riſes with upright, four-cornered ſtems, branching a foot and a half high; oval, obtuſe, hoary leaves; and the ſtalk and branches terminated by long, aggregate, priſmatic ſpikes of ſmall white flowers, having membraneous bractæa double the length of the calix.

[7]ORIGANUM *Smyrnæum.*

*Smyrna Origany.*] Riſes with upright, branchy, hairy ſtalks, a foot and a half high; oval, acutely ſerrated leaves; and umbellate-cluſtered ſpikes of white flowers.

[8]ORIGANUM *Ægyptiacum.*

*Ægyptian Marjoram.*] Riſes with a ſhrubby ſtem, branching a foot and a half high; roundiſh, fleſhy, hollowed, woolly leaves; and the ſtalks and branches terminated by roundiſh, naked ſpikes of pale-red flowers.

All theſe eight ſpecies of *Origanum* flower in July and Auguſt; the flowers are ſmall, monopetalous, ringent, univerſally hermaphrodite, and collected into verticilli round the ſtalks; ſucceeded by ripe ſeed in autumn; though

though in this country the annual Marjoram and the three green-houſe ſorts ſeldom perfect ſeed well, unleſs the autumn proves remarkably fine and warm: in default, however, of ſeed, the propagation of all the perennial ſorts, both hardy and green-houſe kinds, is eaſily effected by ſlips of the roots, &c. And the ſeed of the annual ſort is imported plentifully from France or Italy, by the ſeed-dealers.

Moſt of the ſpecies are remarkable for their agreeable aromatic fragrance and quality.

The firſt three ſorts particularly, have great merit as culinary aromatics for the kitchen-garden, and may alſo be introduced into the pleaſure-ground, in patches in the open borders to encreaſe the variety, and for noſegays, &c. the variegated perennial Marjorams in particular have a pretty effect; they are all eaſily raiſed from ſeed in the open ground in ſpring, and the perennial ſorts alſo by dividing the roots; all of which ſorts, both perennials and annuals, when deſigned for the kitchen-garden, ſhould generally be diſpoſed in four-feet-wide beds, the perennials in rows a foot aſunder, where they will abide for years; and the annual ſort being always raiſed from ſeed annually, it may either remain where ſowed, or the young plants may be planted out in rows ſix or eight inches diſtance; and when deſigned to have any of the ſorts in the pleaſure-garden diſpoſe them about the borders in patches.

But the laſt five ſpecies being exotics from warm countries; they require ſhelter here in winter, ſo muſt be potted and placed in the green-houſe collection, or may be preſerved all winter in a common garden-frame, furniſhed with lights to put on in nights and cold weather.

*Propagation, &c. of all the Sorts.*

Their different methods of propagation are; the hardy perennial ſpecies by ſeed and by ſlipping the roots; the annual ſort only by ſeed annually; and the five green-houſe kinds principally by ſlips and cuttings.

Two Hardy Perennial Sorts.—Both theſe hardy perennials may be propagated by ſeed, and by parting the roots.

By Seed.—This may be had at the ſeed-ſhops: ſow it in ſpring, March or April, in any bed or border of light earth, and rake it in with a light hand; they will ſoon come up: when the ſeedlings are a few inches high, plant them out in moiſt weather, in rows ten or twelve inches diſtance, finally to remain, giving occaſional waterings till freſh rooted.

By Parting the Roots.—Autumn is the beſt ſeaſon, though it may alſo be performed ſucceſsfully in ſpring. Having ſome large plants, ſlip or divide the roots into ſlips, each furniſhed with fibres; which plant in rows, as directed for the ſeedlings, giving occaſional waterings, and they will readily grow, and become good buſhy plants by autumn following.

Their general culture is the keeping them clean from weeds; and every autumn cut down all decayed ſtalks; looſen the earth between the plants; at the ſame time digging the alleys, ſpread a little of the earth over the ſurface of the beds.

When any are intended for the pleaſure-garden, remove them in autumn or ſpring, with little balls of earth about their roots, and plant them where wanted.

Annual Sort.—This plant is raiſed by ſeed only: ſow it annually in ſpring towards the latter end of March, or in April, on a warm dry border, and rake it in; or may be ſowed in ſhallow drills: the plants will ſoon come up, and may either remain where ſowed, thinning them to four or five inches diſtance; or when two inches high may be planted out in moiſt weather, in rows ſix inches aſunder, giving a due ſupply of water till freſh-rooted, and they will ſoon cover the ground, and not need any farther culture.

When any are deſigned for the pleaſure-garden, the ſeed may be ſowed in patches where you would have them remain to flower.

Green-houſe Kinds.—All theſe ſorts are propagated by ſlips or cuttings of the young ſhoots in ſpring and ſummer. If you plant them early, let it be in pots, and plunge them in any hot-bed, they will readily take root; but if in ſummer, they may be planted either in pots, or in a ſhady border. In either mode of planting, give water directly, which repeat as occaſion may require in moderate quantities; and if thoſe that are planted in the open air, either in pots, or in the full ground, are covered down with hand-glaſſes, it will facilitate their rooting; but the glaſſes muſt be removed when the plants begin to ſhoot at top: the plants in either way will be rooted the ſame year; and towards autumn may be potted off ſeparately into ſmall pots, and afterwards managed as other hardy green-houſe exotics.

ORNITHOGALUM, Star of Bethlehem.

This genus compriſes ſeveral herbaceous, bulbous-rooted, flowery perennials, for adorning the pleaſure-garden, and one for the green-

green-houſe collection; having all large bulbous roots, crowned moſtly with long, narrow, carinated, and enſiforme leaves, and upright naked flower-ſtalks annually, riſing from half a foot to a yard high in different ſorts, terminated in long, large ſpikes of hexapetalous, ſtar-ſhaped, white flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, ſix ſpear-ſhaped petals, erect to the middle, and plane and ſpreading above, and are permanent. STAMINA, ſix erect filaments half the length of the corolla, and ſimple antheræ. PISTILLUM, an angular germen, awl-ſhaped permanent ſtyle, and an obtuſe ſtigma. PERICARPIUM, a roundiſh, angular, trivalvate, trilocular capſule, containing many roundiſh ſeeds.

Of this ſpecies there are cultivated in our gardens about ſix hardy ſpecies for the open borders, and one tender kind requiring ſhelter of a green-houſe, &c. in winter.

*Hard Kinds, for the Open Ground.*

[1]ORNITHOGALUM *Pyramidale.*

*Pyramidical, large-ſpiked, Portugal Star of Bethlehem.*] Hath a very large, oval, bulbous root; crowned with long, keel-ſhaped, dark-green leaves; amidſt them an upright, firm, naked flower-ſtalk, near a yard high; terminating in a very large, long, pyramidal ſpike of numerous, aſcending, white, ſtarry flowers; appearing in June.

[2]ORNITHOGALUM *Pyreniacum.*

*Pyrenean Green-flowered Star of Bethlehem.*] Hath a large onion-like bulbous root; crowned with long, keel-ſhaped, ſpreading leaves; an upright, naked flower-ſtalk, half a yard or two feet high, terminated by a very long ſpike of yellowiſh-green flowers on long ſpreading pedunculi, which as the fruit ripens becomes gradually erect, nearly approaching the ſtalk; flowering in May.

The flowers of this ſpecies poſſeſs an agreeable ſweet ſcent. The plant is a native of the Pyrenian mountains; alſo of England, in ſome meadows, and by way-ſides.

[3]ORNITHOGALUM *Latifolium.*

*Broad-leaved Arabian Star of Bethlehem, ſometimes called Alexandrian Lily.*] Hath a very large, roundiſh, bulbous root; crowned with broad, long, ſword-ſhaped leaves, ſpreading on the ground; an upright, thick, ſtrong, naked flower-ſtalk, two or three feet high; terminating in a long, looſe ſpike of many large, ſtarry, white flowers, on long pedunculi; appearing in June.

This is a hardy exotic of Arabia and Ægypt.

[4]ORNITHOGALUM *Umbellatum.*

*Umbelliferous Star of Bethlehem.*] Hath a large, roundiſh, white, bulbous root; crowned with long, narrow, keel-ſhaped, white-ſtreaked, ſpreading leaves; an upright, naked flower-ſtalk, five or ſix inches high, terminated by taller pedunculi; ſuſtaining a corymboſe umbel of white flowers, having the outſide ſtriped with green; appearing in April and May.

It grows wild in England, &c. in ſome woods and meadows.

[5]ORNITHOGALUM *Luteum.*

*Yellow Star of Bethlehem.*] Hath a ſmall, roundiſh, bulbous root; crowned with two or three narrow, keel-ſhaped leaves; an upright, two-leafed flower-ſtalk, ſix inches high; terminated by a ſimple umbel of yellow flowers; appearing in April.

It grows wild in England, &c. on the borders of uncultivated fields, meadows, and paſtures.

[6]ORNITHOGALUM *Nutans.*

*Nodding Star-flower of Naples.*] Hath a large, compreſſed, bulbous root; long, narrow, keel-ſhaped, dark-green leaves; an upright naked flower ſtalk, about a foot high; terminated by a looſe ſpike of flowers hanging on one ſide, white within, and of a greyiſh-green without, and with a ſtamineous, companulated nectari. Flowering in April and May.

Of the above ſix hardy *Ornithogalums*, the firſt three are the moſt ornamental, and moſt noted ſorts in the Engliſh gardens; the other three are alſo kept in many gardens for variety: all the ſorts are exceeding hardy, and will proſper any where.

*Tender Kind for the Green-houſe Collection.*

[7]ORNITHOGALUM *Capenſe.*

*Cape Ornithogalum.*] Hath a large, irregular, tuberous, dark-brown root; crowned with heart-ſhaped-oval, ribbed leaves, elevated on foot-ſtalks; upright, ſlender, naked ſtalks, about a foot high; terminated by a looſe ſpike of greeniſh-white flowers; appearing in October and November.

It is an exotic from the Cape of Good-Hope.

*Variety.*] With pale-blue flowers.

All theſe plants are perennial in root, but annual in leaves and ſtalks, which in the ſix hardy ſorts riſe annually in the ſpring, and

flower

flower in their proper ſeaſon: the flowers conſiſt univerſally of ſix petals that expand themſelves at top like the figure of a ſtar; and being numerous in each ſpike, are very conſpicuous; and in the tall ſorts make a very ornamental appearance: ſucceeded in all the kinds by plenty of ripe ſeeds in autumn: this, however, is rarely wanted, for the plants propagate exceedingly by off-ſets of the roots, which every ſecond year, in ſummer when they have done flowering, and the leaves and ſtalks decay, may be taken up, and the off-ſets ſeparated for encreaſe.

The ſix hardy ſorts are proper furniture for the pleaſure-garden, placing the larger growing ſorts in the moſt conſpicuous parts, in aſſemblage with other bulbous flowers; planting the ſorts in general three or four inches deep, and they may remain unremoved two or three years, when the roots will be increaſed by off-ſets into large bunches, each exhibiting a large cluſter of flowers.

And if ſome roots of the *Ornithogalum Pyramidale*, &c. are planted in large pots, one root in each, in order for moving occaſionally to adorn any particular compartment, they, when in bloom, will have a fine effect.

The *Ornithogalum Capenſe* muſt be always kept in pots of light earth, for the convenience of moving them to the ſhelter of a green-houſe or garden-frames in winter.

*The Propagation, &c. of all the Sorts.*

The propagation of all the ſorts is effected abundantly by off-ſets of the roots.

The ſix hardy ſorts in particular multiply by off-ſets in great plenty, if they ſtand two or three years, eſpecially the ſmaller ſorts; the larger kinds alſo of ſome ſtanding throw out off-ſets abundantly enough for a plentiful increaſe; and the beſt ſeaſon for removing all the ſorts in order to ſeparate the off ſets is July and Auguſt, when their leaves and ſtalks decay; and the roots may either be planted again in Auguſt or September, or kept till October or November, &c. but remarking the autumnal-planted bulbs will flower much ſtronger than thoſe not planted again till ſpring. Obſerve to plant the off-ſets in nurſery-beds for a year, managing the whole as directed for other hardy bulbs. See BULBUS.

The Cape *Ornithogalum* is alſo propagated by ſlips or off-ſets of the roots, which may be ſlipped when the leaves and ſtalks decay; planting each ſlip or off-ſet in a ſeparate pot of good light earth; and place them to have ſhelter from froſt and exceſſive wet weather in winter, and in the full air in ſummer.

OROBUS, Bitter Vetch.

This genus conſiſts of hardy, herbaceous, fibrous-rooted, very floriferous perennials for the embelliſhment of the pleaſure-garden; riſing with erect ſtems, from about one to two feet high, ornamented with winged leaves of from two to ſeveral pair of lobes; and at the axillas and top of the ſtalks, looſe ſpikes and cluſters of papilionaceous, purple and blue flowers of ornamental appearance.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, tubular, and five-parted at the top. COROLLA, is papilionaceous, with a heart-ſhaped ſtandard, two long connivent wings, a bifid, aſſurgent, acuminated keel, ſwoln at the baſe. STAMINA, ten diadelphous filaments, and oblong antheræ. PISTILLUM, a cylindric compreſſed germen, a bent ſtyle, and narrow downy ſtigma. PERICARPIUM, a long, taper, acute, unilocular pod, having many roundiſh ſeeds.

The plants of this genus are moſtly natives of woods and commons in different parts of the world; but ſeveral of the ſorts are retained in gardens for the beauty of their flowers.

The moſt material ſpecies are the following ſeven.

[1]OROBUS *Vernus.*

*Vernal Orobus.*] Hath ſtrong fibrated roots; upright ſimple ſtalks, riſing a foot high; garniſhed with pinnated leaves of two pair of oval lobes, attended by half-arrow-pointed, entire ſtipula; and at the axillas ſhort ſpikes of flowers of different colours in the varieties; appearing in March.

*Varieties.*] Purple-flowered ſpring *Orobus*—deep blue-flowered—pale blue-flowered.

[2]OROBUS *Tuberoſus.*

*Tuberous-rooted Orobus, ſometimes called Wood Pea.*] Hath a tuberous, knotty, creeping root; upright, angular, ſimple ſtems, about a foot long; pinnated leaves, of four pair of lanceolate lobes, attended by half-arrow-pointed ſtipula; and at the axillas long pedunculi, each having two or three reddiſh flowers; appearing in April and May.

It is a reſident of ſhady woods in England and other countries.

[3]OROBUS *Lathyroides.*

*Lathyroides, or Baſtard Lathyrus.*] Riſes with upright branchy ſtems about a foot high; con-

conjugated, almoſt cloſe-ſitting leaves, having indented ſtipula; and at the axillas ſhort pedunculi, each terminated by a ſhort ſpike of bright blue flowers.

4 OROBUS *Lunata.*

*Lunated Siberian Orobus.*] Riſes with upright, unbranching ſtalks, a foot and a half high; pinnated leaves, of four or five pair of oval-oblong lobes, attended by broad lunated or moon ſhaped ſtipula; and at the axillas ſhort pedunculi ſupporting large purple flowers; appearing in April.

5 OROBUS *Sylvaticus.*

*Sylvian, or Wood Orobus.*] Riſes with decumbent, branching, hairy ſtalks, a foot and a half long; winged leaves of ſeven pair of lobes; and at the axillas cloſe ſpikes of purple flowers; appearing early in June.

This grows naturally in woods in ſeveral parts of England.

6 OROBUS *Niger.*

*Black Orobus.*] Riſes with upright branchy ſtems, two feet high; pinnated leaves, of ſix pair of oval-oblong lobes; and at the axillas long pedunculi, each ſupporting ſeveral purple flowers; appearing in May.

7 OROBUS *Pyreniacus.*

*Pyrenean Orobus.*] Riſes with upright, branchy ſtems, a foot and a half high; pinnated leaves, of two pair of ſpear-ſhaped nervous lobes; and at the axillas long pedunculi, terminating in looſe ſpikes of purple flowers; appearing in May.

All theſe ſeven ſpecies of Orobus have ſtrong fibrated roots, which are perennial, but are annual in ſtalk; riſing early in ſpring and decay in autumn.

They are all very hardy plants, and proſper in any common ſoil of a garden.

Moſt of the ſorts are very floriferous, and the flowers conſpicuous and ornamental for adorning the flower compartments; the flowers are univerſally of the papilionaceous or butterfly kind, conſiſting each of four irregular petals, i. e. a ſtandard, two wings, and a keel; and are all ſucceeded by long taper ſeed-pods, furniſhing plenty of ripe ſeed in autumn; by which the plants may be propagated abundantly, as alſo by parting the roots.

With reſpect to their merit in gardens, they may be employed in any of the compartments of the pleaſure-ground as flowery plants: they will flouriſh any where and exhibit a pretty variety when in flower.

*Their Propagation, &c.*

Their propagation is by ſeed and by parting the roots.

By Seed.——All the ſorts furniſh plenty: ſow it in autumn, i. e. September, or beginning of October, or early in ſpring, in any bed or border, and rake them in, and thoſe of the autumn-ſowing will readily come up in ſpring; but thoſe of the ſpring-ſowing do not come up ſo freely: as the plants advance, clear them from weeds, and give occaſional waterings; and in June or July, when a few inches high, prick them out, in moiſt weather, in nurſery-rows half a foot aſunder, to remain to gain ſtrength till October or November, then tranſplant them where they are to remain.

By parting the Roots.——Autumn, when their ſtalks decay, is the beſt time for this: having recourſe to ſome large plants, divide the roots into ſlips, each furniſhed with fibres, and plant the largeſt at once where they are to remain; and the ſmalleſt may be planted in nurſery-rows for a year.

OSTEOSPERMUM, Hard-ſeed, commonly called Hard ſeeded *Chryſanthemum.*

This genus furniſhes ſhrubby exotics for the green-houſe collection, riſing with ſhrubby durable ſtems, branching ſeveral feet high, garniſhed with oval and ſpear-ſhaped leaves; and the branches terminated by yellow compound flowers.

Claſs and order, *Syngeneſia Polygamia Neceſſaria.*

*Characters.*] CALIX, a compound flower, having a ſimple, hemiſpherical, many-parted cup. COROLLA, a compound radiated flower, of many ſmall florets, being funnel-ſhaped, males or hermaphrodites in the diſk or middle, and flat tongue-ſhaped females in the radius. STAMINA, in the hermaphrodites five very ſhort filaments, and cylindric antheræ. PISTILLUM, in the hermaphrodites a ſmall germen, ſlender ſtyle, and obſolete ſtigma, and in the females a globular germen, ſlender ſtyle, and an emarginated ſtigma. PERICARPIUM, none, in each female floret a ſingle ſeed, as hard as bone.

The plants of this genus are moſtly natives of Africa, and require ſhelter of a green-houſe here in winter.

The ſpecies are:

1 OSTEOSPERMUM *Moniliferum.*

*Moniliferous Æthiopian Oſteoſpermum.*] Hath a ſhrubby ſtem, branching ſix or eight feet high,

high, having a ſmooth grey bark; oval, ſerrated, thick, hoary, alternate leaves, on decurrent foot-ſtalks; and the branches terminated by cluſters of yellow flowers.

[2]OSTEOSPERMUM *Piſiferum.*

*Piſiferous Cape Oſteoſpermum.*] Hath a ſhrubby ſtem, branching ſeven or eight feet high, having ſoft woolly branches; ſpear-ſhaped, pointed, ſerrated, ſmooth leaves, on very ſhort, bordered foot-ſtalks; and the branches terminated by cluſters of yellow flowers.

[3]OSTEOSPERMUM *Spinoſum,*

*Spinous African Oſteoſpermum.*] Hath a low ſhrubby ſtem, branching three or four feet high, armed with branchy ſpines; oblong, narrow, clammy leaves, placed irregularly; and the branches terminated by yellow flowers ſingly.

[4]OSTEOSPERMUM *Polygaloides.*

*Polygaloide Æthiopian Oſteoſpermum.*] Hath a ſhrubby ſtem, branching four or five feet high; ſpear-ſhaped, entire, ſmooth, decurrent leaves, placed almoſt imbricatum; and the branches terminated by yellow flowers ſingly.

All theſe *Oſteoſpermums* are durable in root, ſtem and branches, retaining their leaves moſt part of the year: the firſt ſort is that which is the moſt common in the Engliſh gardens. They flower in ſummer; the flowers are univerſally compound and radiated; rarely ſucceeded by good ſeeds in England.

The plants muſt always be kept in pots for moving to ſhelter of a green-houſe in winter, and managed as myrtles and other green-houſe ſhrubs.

Their propagation is by cuttings any time in ſummer. Chuſe the young ſhoots, which plant in pots, ſeveral in each, giving water and occaſional ſhade, for a month or ſix weeks, when they will be rooted; and before winter ſhould be potted off ſeparately, and placed among the other green-houſe exotics.

OTHONNA, African Ragwort.

The plants of this genus are ſhrubby and underſhrubby ever-green exotics of Africa, for the green-houſe, riſing from about two to four or five feet high, ornamented with pinnatifid and entire ſpear-ſhaped leaves, and the branches terminated by compound radiated yellow flowers.

Claſs and order, *Syngeneſia Polygamia Neceſſaria.*

*Characters.*] CALIX, a compound radiated flower, having a ſingle monophyllous cup, divided into eight or twelve parts. COROLLA, a compound radiated flower, of numerous ſmall florets, the middle or diſk compoſed of many tubular hermaphrodite florets, and the ray of eight or twelve flat, tongue-ſhaped, tridented, female florets. STAMINA, in the hermaphrodite florets five ſhort filaments, and long cylindric antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and in the hermaphrodites a ſimple bifid ſtigma, which in the females is large and reflexed. PERICARPIUM, none, each female floret is ſucceeded by one oblong ſeed, crowned with down, lodged in the permanent calix.

The moſt noted ſpecies are;

[1]OTHONNA *Pectinata.*

*Pectinated-leaved Othonna.*] Hath a ſhrubby ſtem, branching numerouſly two or three feet high, the branches covered with a hoary down; oblong, pinnatifid, hoary, white leaves, being cut pinnatifid-wiſe almoſt to the mid-rib, into many narrow parallel ſegments, arranged in a pectinated manner, or reſembling the teeth of a comb; and at the axillas and ends of the branches long pedunculi, terminated by large yellow flowers, with ſpreading rays.

[2]OTHONNA *Abrotanifolia.*

*Abrotanum-leaved Othonna.*] Hath a low, ſhrubby, jointed ſtem, branching about two feet high; thick, finely multifid-pinnated, ſouthernwood-like leaves; and the branches terminated by yellow flowers.

[3]OTHONNA *Coronopifolia.*

*Coronopus-leaved Othonna.*] Hath a ſhrubby ſtem, branching four or five feet high; ſpear-ſhaped, narrow lower leaves, the upper ones ſinuated and indented; and the branches terminated by umbellate cluſters of yellow flowers.

Theſe ſhrubs flower in ſummer and autumn: the flowers are in general compound and radiated, continuing in ſucceſſion two or three months, but are rarely ſucceeded by good ſeed in our gardens.

They are proper furniture for the green-houſe collection, and being tender muſt always be kept in pots for moving to ſhelter in winter; they will have a very pretty effect in this collection, both by their mode of growth, leaves, and flowers: managing them generally as directed for other ſhrubby exotics of the green-houſe. See GREEN-HOUSE PLANTS.

Their propagation is by ſlips and cuttings of the young ſhoots, planted any time in ſummer,

ſummer, before the latter end of July, either in pots, or in a bed or border, watered and ſhaded occaſionally from the ſun, till rooted, which they will effect the ſame ſeaſon; or if they are covered cloſe with hand-glaſſes and ſhaded, it will facilitate their rooting: early in autumn pot them ſeparately, and manage them as other green-houſe ſhrubs.

# P.

PÆONIA, Peony.

This genus furniſhes large herbaceous flowery perennials, moſtly of the tuberous-rooted kind; having roots compoſed of large fleſhy tubers, ſending up ſtrong annual ſtalks, from one or two to three feet high; garniſhed with large, many-lobed, ſpreading leaves; and terminated by very large, pentapetalous, polyandrous flowers.

Claſs and order, *Polyandria Digynia.*

*Characters.*] CALIX, five roundiſh, concave, reflexed, equal leaves. COROLLA, five large, roundiſh, concave, ſpreading petals. STAMINA, numerous ſhort capillary filaments, and large, oblong, quadrangular, erect antheræ. PISTILLUM, two or three downy germina, no ſtyles, but oblong compreſſed obtuſe, coloured ſtigmas. PERICARPIUM, two or three oval-oblong, ſpreading, reflexed, downy, univalvular, unilocular capſules, having many oval ſeeds.

There are only two ſpecies, one of which, however, common Peony, admits of many elegant varieties, with both ſingle and double flowers; but the doubles being remarkably large, and the petals multiplied in many ſeries to the very centre, are conſiderably more beautiful and eſtimable than the ſingles, which have only five petals, according to their *characteriſtic* deſcription; but the petals are innumerable in the double varieties, forming a fine full flower; much larger than the biggeſt double roſe.

The ſpecies are;

[1]PÆONIA *Officinalis.*

*Common Officinal Peony.*] Hath a large root, compoſed of many thick fleſhy tubers, hanging by ſtrings to the main head; upright, round, robuſt, ſmooth ſtalks, branching half a yard or two feet high, or more; garniſhed with very large, many-lobed leaves, compoſed of oblong-oval folioles, ſpreading widely all around; and the ſtalk and branches terminated by large, deep-red flowers ſingly, having numerous ſtamina, with yellow antheræ; ſurrounding two, three, or more germina, ſucceeding to ſo many capſules, opening longitudinally, and diſcover their ſeed, gradually ripening to a dark-purple, or blackiſh colour. Flowering in May and June.

Of this ſpecies there are two noted varieties, called, Male Peony, and Female Peony; each of which comprehending alſo ſome varieties, viz.

*Male Peony.*]—Hath lobated, dark-green leaves, having large oval folioles cut on the ſides; and very large, ſingle, red flowers; ſucceeded by capſules remarkable for turning backward, opening and diſplaying their red inſide, together with the numerous ſeeds in a ſingularly agreeable manner, appearing very ornamental after the flower is paſt.

*Female Peony.*]—Hath unequally lobated pale-green leaves, with narrow lobes, more frequently cut on the edges, and ſmaller deep-purple flowers.

*Of theſe two principal Varieties are the following;*] Double red-flowered—double deep-red-flowered—double purple-flowered—double roſe-coloured—double white-flowered—double black-flowered——Portugal deep-red ſweet-ſcented Peony——Conſtantinople large blood-red Peony—dwarf white Peony.

All theſe ſorts, conſidered as flowery plants, are very ornamental in their flowers, particularly the doubles.

The plants have alſo great merit for medical uſes.

PÆONIA *Tenuifolia.*

*Narrow-leaved Peony.*] Hath a thick, fleſhy, creeping root; upright unbranching ſtalks, riſing a foot and a half high; ſmalliſh multipartite leaves, having the lobes divided into a multitude of narrow ſegments; and the ſtalks terminated by red flowers placed ſingly.

Both theſe ſpecies of *Pæonia*, and all the varieties, are perennial in root, but annual in ſtalk and leaves; riſing in ſpring, form large buſhy plants, having the flowers erect in the midſt of them; and wholly die gradually to the ground at the approach of winter.

They flower in May and June, continuing in beauty a month or ſix weeks: the flowers are very large in the firſt ſpecies and varieties; and in their ſingle or *characteriſtic* ſtate, in all the ſorts, conſiſt of five large roundiſh petals; but in the doubles the petals are multiplied in many ſeries inward to the centre, forming very large full flowers, which in moſt of the ſorts are ſucceeded by plenty of ripe ſeed in autumn, by which the plants may be raiſed in the common ground in great abundance, as well as by off-ſets of the roots. See their *Propagation*.

All the ſorts are hardy plants that will flouriſh in any common ſoil of a garden in almoſt any ſituation, either in open expoſures, or under ſhade of trees, &c. and will abide by the roots a great number of years, flower annually, and encreaſe exceedingly by off-ſets for propagation.

They are proper ornaments as flowery plants, for large borders and other compartments, and may be had at all the public nurſeries. Obſerving that the beſt ſeaſon for removing them is in autumn, when their ſtalks and leaves are decayed; planting one here and there in different parts, placing them with the crown of the root a little within the ſurface of the earth, and at a yard at leaſt diſtance from other plants, for they extend themſelves widely every way, aſſuming a large buſhy growth; which, together with their conſpicuous large flowers, exhibit a fine appearance.

After the flowers are gone, the capſules opening lengthways, diſcover their coloured ſeeds very ornamentally, eſpecially the Male Peony and varieties; and to forward this, ſome ſlit the capſules open on the inſide at the proper valve, whereby they will expand much ſooner, and diſplay their beautiful ſeed.

The plants may be ſuffered to remain ſeveral years unremoved, till the roots are encreaſed into very large bunches, and may then be taken up, when the ſtalks decay, in autumn, and divided.

*Their Propagation, &c.*

Their propagation is effected moſt commonly by dividing the roots; but they may alſo be raiſed abundantly from ſeed.

By dividing the Roots.—The roots multiply faſt by off-ſets; and the beſt time for removing and ſeparating them is Auguſt and September. When the ſtalks are decayed, then the whole root may be taken up and divided, each ſlip or off-ſet, having at leaſt one eye or bud at its crown, will make a proper plant. I would not, however, adviſe dividing them into very ſmall ſlips, unleſs when as great an encreaſe as poſſible is wanted: in which caſe they may be divided as ſmall as may be, provided each ſet is crowned with one or more buds; and in either caſe it is adviſeable they be all planted again ſoon after; for although theſe roots, if removed at the proper time as above, may upon occaſion be kept out of the ground ſome time, yet when planted again ſoon after their removal, they will flower much ſtronger; obſerving, you may plant the larger off-ſets at once where they are to remain; and the ſmaller ones in nurſery-beds to ſtand a year or two to gain ſtrength, then tranſplanted into their places of final deſtination.

By Seed.—All the ſingle-flowered kinds in particular produce plenty, and from which both ſingle and double-flowered plants are obtained. Autumn, ſoon after the ſeed is ripe, is a very ſucceſsful ſeaſon for ſowing; though it may alſo be performed in ſpring, and may be ſowed in any bed or border of light earth, either by broad-caſt, and raked in, or in ſhallow drills, ſix inches aſunder, covering the ſeeds half an inch deep: they will readily come up in April or May; keep them clean from weeds, and give moderate waterings in dry weather; and as it is proper they ſhould remain two ſeaſons in the ſeed-bed, it is adviſable in autumn to ſpread an inch depth of light earth over the ſurface of the bed: the next year, in September, tranſplant them where they are to remain.

PANCRATIUM *(Pancratium Lily)* Sea Daffodil.

This

This genus conſiſts of large bulbous-rooted, herbaceous, flowery perennials, of very ornamental appearance for the pleaſure-ground and ſtove collection, having very large bulbous roots, crowned with long leaves, ſome very narrow, others broad; and upright robuſt flower-ſtalks, from one to two or three feet high, terminated by a large ſpatha, or ſheath, protruding ſome many, others but one or two hexapetalous, liliaceous, white flowers, of great beauty and fragrance.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, an oblong ſpatha, opening on one ſide, protrudes many flowers, and withers. COROLLA, ſix ſpear-ſhaped petals, and in the middle a monopetalous, funnel-ſhaped nectarium, ten or twelve-parted, and ſpreading at top. STAMINA, ſix awl-ſhaped filaments inſerted into the brim of the nectarium, and oblong incumbent antheræ. PISTILLUM, an obtuſe trigonal germen under the corolla, long filiforme ſtyle, and an obtuſe ſtigma. PERICARPIUM, a roundiſh, trigonous, trilocular capſule, having many globular ſeeds.

Of this genus there are two hardy ſpecies for the pleaſure garden, and five tender kinds for the ſtove.

*Hardy Kinds.*

[1]PANCRATIUM *Maritimum.*

*Maritime Pancratium, or Common Sea Daffodil.*] Hath a very large, oblong, bulbous, dark-coated root; crowned with tongue-ſhaped leaves a foot-long, encompaſſed at bottom with a ſort of ſheath; amidſt them an upright, robuſt, naked flower-ſtalk, a foot and a half high, ſurmounted by a multiflorous ſpatha, protruding ſeveral large white flowers, having plane petals. Flowering in the latter end of Auguſt or in September.

It grows naturally on the ſea-coaſt of France and Spain.

[2]PANCRATIUM *Illyricum.*

*Illyrian Multiflorous Pancratium.*] Hath a large, oval, bulbous, dark-coated root; crowned with ſword-ſhaped leaves, a foot and a half long, and two inches broad; an upright, thick, ſucculent, naked flower-ſtalk, near two feet high; terminated by a multiflorous ſpatha, protruding ſix or eight white flowers, having the ſtamina longer than the nectarium. Flowering in June and July.

Both theſe hardy *Pancratiums* proſper in the open ground, but muſt have a warm dry ſituation, and a light ſoil, and ſheltered occaſionally from ſevere froſt, where they will abide for many years by the root, renewing their leaves and flower-ſtalks annually, and encreaſe freely by off-ſets.

*Tender Kinds for the Hot-houſe.*

Theſe ſorts being tender exotics from the warm parts of the Indies, in this country muſt be kept in pots, in order for being placed always in the hot-houſe, where they will exhibit their beautiful fragrant flowers at different times of the year.

[3]PANCRATIUM *Zeylanicum.*

*Ceylon Uniflorous Pancratium.*] Hath a large oval, bulbous root, crowned with narrow erect leaves, a foot long; an upright, firm, naked flower-ſtalk, fifteen or eighteen inches high, terminated by a uniflorous ſpatha, protruding one large white flower, having reflexed petals.

[4]PANCRATIUM *Mexicanum.*

*Mexican Biflorous Pancratium.*] Hath a large bulbous root; crowned with furrowed leaves, a foot long, and two or three broad; an upright naked flower-ſtalk, about a foot high; terminated by a biflorous ſpatha, protruding two large white fragrant flowers.

[5]PANCRATIUM *Caribbæum.*

*Caribbæan Multiflorous Pancratium.*] Hath a very large bulbous root; crowned with ſpear-ſhaped, moderately-broad, longitudinally-ribbed leaves; an upright, thick, firm, naked flower-ſtalk, two feet high, or more; terminated by a multiflorous ſpatha, protruding many very large, white, fragrant flowers.

[6]PANCRATIUM *Amboinenſe.*

*Amboyna Broad-leaved Multiflorous Pancratium.*] Hath a large, oval, white, bulbous root; crowned with oval, nervous, or deeply ribbed leaves, ſeven or eight inches long, and five or ſix broad, growing on ſhort foot-ſtalks; and an upright, thick, naked flower-ſtalk, near two feet high, terminated by a multiflorous ſpatha, protruding many large white flowers.

*Variety.*] With broad, oval, acuminated leaves, and very fragrant flowers.

[7]PANCRATIUM *Carolinianum.*

*Carolina Multiflorous Pancratium.*] Hath a roundiſh, bulbous root; crowned with very narrow leaves, a foot long; and an upright, robuſt, naked flower-ſtalk, eight or nine inches high, terminated by multiflorous ſpatha, protruding ſeveral flowers, having the ſtamina as long as the nectarium.

All

All theſe plants are perennial in root, but annual in ſtalk, which always decay ſoon after the flower is paſt.

Their ſeaſon of flowering is different, the two hardy ſorts flower here pretty conſtantly at the times mentioned in their deſcription; and as to the tender kinds, they often exhibit their flowers in our ſtoves in the middle of winter, ſometimes in ſpring, ſummer, and autumn; and ſometimes they flower two or times a year, ſo that one or other of them exhibit flowers at almoſt all ſeaſons. The flowers of all the ſorts conſiſt each of ſix petals, and a monophyllous nectarium in the centre, and are very ornamental, and moſt of them exceedingly fragrant; but rarely any of the ſorts, except the *Pancratium Illyricum*, furniſh ripe ſeeds in theſe parts.

They all encreaſe in tolerable plenty in root by off-ſets for propagation.

All the ſorts have great elegance in their flowers, and moſt of them are enriched with a delightful fragrance, and demand our attention for culture in the pleaſure-garden and ſtove.

The two hardy ſorts are proper for the pleaſure-garden, but ſhould have a warm dry ſituation, and light ſoil: the ſeaſon for planting them is autumn, that is, the roots being taken up when their leaves decay, ſhould be planted again ſoon after; placing them about four inches deep, and they will flower the year following; ſuffering the roots to remain unremoved two or three years; when they will be encreaſed by off-ſets, and ſhould be taken up and ſeparated. See their *Propagation*.

Obſerve, in ſevere froſts it will be proper to cover the ground over the roots with litter, to protect them.

The five tender ſpecies muſt be planted in large pots, and placed in the hot-houſe: the ſeaſon for planting and tranſplanting them is when their leaves decay: obſerve this, and plant one root in each pot, which plunge in the bark-bed of the ſtove, where let them always remain; and here they will flower ſtrong at their uſual ſeaſons, and multiply exceedingly by off-ſets.

*Propagation of all the Sorts.*

All the ſorts are propagated by off-ſets of the root, like other bulbs, which may be ſeparated every ſecond or third year, or according as they multiply; the proper time for which is when their leaves decay; planting the off-ſets of the hardy ſorts in nurſery-beds for a year, then tranſplanted where they are to remain; and thoſe of the tender kinds plant in ſeparate pots, plunging them in the bark-bed. Thoſe of all the ſorts will flower in perfection the ſecond year, and in their turn furniſh a proper ſupply of off-ſets for encreaſe.

PAPAVER, Poppy.

The plants of this genus are hardy, herbaceous, fibrous-rooted, flowery plants; principally annuals and perennials, for ornament in gardens, and for medicinal uſe; riſing with upright ſtalks, from one to three feet high, garniſhed with large, deeply jagged and pinnatifid leaves, and terminated by large tetrapetalous polyandrous flowers.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, is oval, and compoſed of two oval, concave, indented leaves that ſoon fall of. COROLLA, four large, roundiſh, plane, ſpreading petals. STAMINA, numerous ſhortiſh filaments, and oblong, compreſſed erect antheræ. PISTILLUM, a large roundiſh germen, no ſtyle, but the germen crowned by a target-ſhaped, plane, radiated ſtigma. PERICARPIUM, a very large, roundiſh, or oval, unilocular capſule, crowned with a plane ſtigma, opening under it in ſeveral places, and is filled with numerous ſmall ſeeds

There are eight or nine ſpecies, and of which four only have claim to attention as garden plants; two annuals, and two perennials: the two former of which compriſe many varieties in reſpect to the ſize, various colourings, variegations, and doubleneſs of their flowers, ſome of which are very beautiful, though all of them rather of a diſagreeable ſcent, and of ſhort duration: the plants, however, are deſigned by nature for excellent purpoſes in medicine; and both the annual and perennial kinds may be employed to encreaſe variety in the pleaſure-garden; they are all very hardy and proſper any where.

*Annual Kinds.*

1 PAPAVER *Somniferum.*

*Somniferous common Garden Poppy.*] Riſes with an upright ſmooth ſtalk, dividing and branching a yard or more high; garniſhed with large, deeply jagged, amplexicaule, ſmooth leaves; and terminated by large, ſpreading, dark-purple, and other coloured flowers in the varieties, having ſmooth cups and capſules. Flowering in June and July.

The

The varieties of this ſpecies are numerous; many of which have great beauty, both in their amazing ſize, doubleneſs. and colourings.

*Varieties of this are.*] Double purple-flowered——double red-flowered——double white-flowered—double variegated purple-and-white-flowered—double variegated red-and-white-flowered—-double red-and-white ſpotted-flowered, or carnation Poppy—double curled-flowered—double fringed-flowered—double feather-flowered—and alſo with ſingle flowers of each ſort.

Obſerve that as there are both ſingle and double flowers of all the above varieties, the ſingles having only four petals, have no merit as garden-flowers; but the double kinds being very large, and the petals numerous, forming a handſome full flower, exhibit a good variety in a garden: the flowers, however, are but of very ſhort duration, and in general of a diſagreeable ſcent.

Moſt of the varieties of this ſpecies are of a ſomniferous nature, i. e. cauſing ſleep: hence it is termed PAPAVER *Somniferum.*

The white officinal Poppy, a variety of this ſpecies, is the principal medicinal ſort; it often grows five or ſix feet high, having large flowers, both ſingles and doubles, ſucceeded by very large heads, or capſules, as big as oranges, filled with very numerous ſeeds (about 8000); and the heads are greatly uſed in medicine; of which is made the *diacodium* of the ſhops; likewiſe from the heads is extracted the *opium* in Turkey; and any part of the plant boiled in water, and ſweetened with ſugar, cauſes ſleep; but ſhould be uſed with caution, becauſe too large a quantity brings on death. The ſeed is alſo good in fevers and inflamatory diſorders; ſo that this variety in particular is propagated in great plenty for ſupplying the ſhops.

All the varieties are raiſed commonly from ſeed in the open ground.

[2]PAPAVER *Rhœas.*

*Rhœas, or Wild Globular-headed Poppy.*] Riſes with an upright, hairy, multiflorous ſtalk, branching a foot and a half high; garniſhed with long, pinnatifid, deeply-cut, hairy leaves; and the ſtalk terminated by many red and other coloured flowers in the varieties; ſucceeded by globular ſmooth capſules. Flowering in June.

This ſpecies is the wild red Poppy of the fields, but being improved by garden-culture, many varieties of different beautiful colours, and exceeding doubleneſs, have been obtained.

*Varieties are.*] Double red-flowered——double purple-flowered—double white-flowered—double variegated-flowered of many fine-coloured varieties——and with ſingle flowers of all the above colours and variegations.

Of the above varieties of this ſpecies, the double kinds only merit attention as flower-plants; the variegated ſorts in particular are very beautiful; but all the flowers of the varieties, like thoſe of the ſomniferous kind, are but of ſhort duration.

*Perennial Kinds, with durable Roots, but annual Stalks.*

[3]PAPAVER *Cambricum.*

*Cambrian, or Welſh Poppy.*] Hath a perennial root; crowned with pinnated, cut leaves; upright, ſmooth, multiflorous ſtalks, a foot and a half high; garniſhed with ſmall pinnated leaves; and terminated by many large yellow flowers; ſucceeded by oblong, ſmooth capſules. Flowering in June.

It grows ſpontaneouſly in Wales and ſome other parts of Britain.

[4]PAPAVER *Orientale.*

*Oriental Poppy.*] Hath a large, thick, perennial root; crowned with long, pinnated, ſawed leaves; upright, rough, uniflorous ſtalks; terminated each by one large, deep-red flower; ſucceeded by oval ſmooth capſules. Flowering in May.

*Variety.*] With double flowers.

All theſe ſpecies of *Papaver* flower principally in June and July, except the oriental kind, which commonly flower in May: the flowers of all the ſorts are large, particularly the annuals, and in their ſingle ſtate, conſiſt each of four large, roundiſh petals; but the double flowers are compoſed of numerous petals, in ſeveral degrees of luxuriance in different varieties, and in all the ſorts are ſucceeded by very large roundiſh capſules filled with numerous very ſmall ſeeds, ripening in autumn.

As to their merit as garden-plants and propagation, obſerve as follow:

Annual Sorts.—Both theſe ſorts furniſhing many varieties with ornamental flowers, the doubles of which in particular make a pretty appearance in the compartments of the pleaſure-garden, when diſpoſed here and there in patches, ſo that we ſhould procure ſeed of the fineſt doubles only, which may be ſowed in autumn or ſpring, at once where the plants are to

to remain, in patches as above, covering it near a quarter of an inch deep; and when the plants are come up an inch or two high, thin them where too thick, to three or four in each patch: here they will flower abundantly; obſerving, when the flowers appear, to cut out all ſuch plants whoſe flowers are of bad colours, and all ſingles and half doubles; leaving only the fine full double flowers: thus by preſerving only the beſt flowers, the blow will be ornamental; and will ripen plenty of ſeed, which, if permitted to ſcatter, numbers of plants will riſe naturally.

The flowers, however, of all theſe annuals are but of a ſhort continuance, which in very hot weather, are often but of one day's duration, but are ſucceeded by others on the ſame plant; the large doubles having numerous petals, they, by falling daily, cauſe a littering appearance.

When deſigned to cultivate the ſomniferous kinds for uſe, may ſow the ſeed by broadcaſt, in any open ground, and rake them in; and when the plants are three inches high, hoe them out to a foot diſtance, there to ſtand to perfect their ſeeds.

Perennial Sorts.—Both theſe ſorts are employed to form variety in large gardens; they may be placed any where, and plants of both ſorts may be procured at the nurſeries: in autumn or ſpring, planting them directly where they are to remain.

Theſe two ſorts may be propagated by ſeed and by parting the roots.

By Seed.—Sow it in autumn, or early in ſpring, in any bed or border, and rake it in; when the plants are three or four inches high, plant them out in nurſery-rows to remain till autumn, then tranſplant them where they are finally to remain, and will flower in ſummer following.

By Roots.—In autumn or early in ſpring you may ſlip the roots, preſerving fibres to each ſlip, which planted become proper plants, and will flower the following ſeaſon.

PANICULA, Panicle; a mode of flowering, in which the common flower-ſtalk branches into ſeveral ſmaller, diſperſed along its ſides; and theſe ſmaller ones are again variouſly ſub-divided into others; each diviſion ſupporting flowers and fruit, hanging looſely; ſuch as a head of oats, and many other plants.

A Panicle is of two ſorts, diffuſe, and coarctate.

A diffuſe Panicle (*Panicula diffuſa*) is when the partial flower-ſtalks, or pedicles, diverge, and the fructifications hang looſe, ſo as to form in the whole a ſpreading looſe panicle.

A coarctate Panicle (*Panicula coarctata*) is when the pedicles approach pretty cloſe together, ſo as to form a narrow ſtraight panicle.

PAPILIONACEUS *Flos*; a butterfly-ſhaped flower, ſuch as all the pea-bloom kinds. See COROLLA *Papilionacea*.

A Papilionaceous, or butterfly-ſhaped flower, conſiſts of four or five very irregular petals; and from their figure and poſition, bear an obvious reſemblance in moſt of the genera, to a butterfly expanding its wings for flight; exemplified in all the ſorts of pea, bean, kidney-bean, laburnum, &c.

The different petals of a Papilionaceous flower are characterized by diſtinct names; the upper one commonly the largeſt, and ſtanding erect, is termed the ſtandard, (*vexillum*;) the two ſide petals the wings, (*alæ*;) and the lowermoſt, which is generally concave, and united and divided at bottom, is called the keel, (*carina*,) from its reſemblance to the keel of a boat; is ſometimes of one petal, and ſometimes two united.

Plants of the Papilionaceous tribe conſiſt both of herbaceous plants and trees; and are of the claſs and order *Diadelphia Decandria*. See CLASSIS.

Some Papilionaceous flowers are of various ſizes in different plants; ſome have very large petals, others middling, and others very ſmall; and ſome are furniſhed with the ſtandard only, as in the genus *Amorpha*; and in ſome the different petals are ſo ſituated as to form the appearance of a regular flower, whereby the Papilionaceous, or butterfly-ſhape, is not very conſpicuous; far the greater part, however, have all the proper petals, repreſenting the above form.

All the Papilionaceous flowers are hermaphrodite, and have commonly ten united ſtamina, generally *Diadelphous*, or of two ſets; one ſet is compoſed of nine ſtamina in one crooked body, terminated by nine antheræ; and the ſecond ſet conſiſts of one filament only, lying along the cliſt of the large bundle; ſometimes ſeparate, or totally diſtinct, and ſometimes pretty cloſely attached: in the midſt is a ſlender crooked ſtyle, crowned by a downy

ſtigma,

ſtigma; ſucceeded by that ſort of ſeed-pod termed legum (*legumen*) ſuch as the pea, bean, kidney-bean, &c. being oblong, more or leſs compreſſed, with two valves, and one, two, or more, *loculi* or cells, containing a few ſeeds, of different ſhapes and magnitudes in different genera, all faſtened along one ſuture, or ſeam, only. See LEGUMEN and PERICARPIUM.

Papilionaceous-flowered plants are very numerous, and conſiſt both of herbaceous plants and trees, as aforeſaid: of the former many are trailing or climbing plants, with long weak ſtalks, and being as it were helpleſs of themſelves, indulgent nature has either provided them with tendrils to climb and faſten themſelves to the neighbouring trees and buſhes, as in all the ſorts of peas; or their ſtalks are endued with a faculty of twining themſelves around the bodies in their neighbourhood for the purpoſe of ſupport. The climbing ſorts of kidney-bean furniſh examples; and as to the tree and ſhrub kinds of this tribe, they obtain in ſtature, from one yard to ſixty or ſeventy feet. Moſt of the ſorts, both of the herbaceous and the ſhrub and tree kinds, are garniſhed with alternate leaves of different forms, being either ſimple, fingered, or winged, but moſt commonly of this laſt form, having the lobes entire, and ſometimes placed in pairs, as in *lathyrus*, but moſt commonly the winged leaf is terminated by an odd lobe; and the winged or pinnated leaves of this order, have generally a daily, or periodical motion, depending upon the progreſs of the ſun in his diurnal courſe. See MOTUS.

The principal plants of this tribe are the following, conſiſting of herbaceous plants and trees.

*Amorpha*, baſtard indigo—*anthyllis*, ladies finger—*ebenus*, ebony of Crete——*erythrina*, coral-tree—*geniſta*, ſingle-ſeeded broom——*lupinus*, lupine—*ononis*, reſt harrow—*ſpartium*, common broom—*ulex*, furz or whins—*æſchynomene*, baſtard ſenſitive-plant——*colutea*, bladder-ſena—*coronilla*, jointed-podded *colutea*—*cytiſus*, laburnum, baſe-trefoil, &c.—*glycine*, Carolina kidney-bean-tree—*glycyrrhiza*, liquorice—*hedyſarum*, French honey-ſuckle—*lathyrus*, everlaſting-pea——*lotus*, bird's-foot trefoil—*medicago*, moon and ſnail trefoil——*orobus*, bitter vetch—*phaſeolus*, kidney-bean—*piſum*, pea—*robinia*, falſe acacia—*ſcorpiurus*, caterpillar-plant—*trifolium*, trefoil—*vicia*, vetch and garden-bean—*aſtragalus*, liquorice-vetch, goat's-thorn—*piſcida*, dog-wood-tree.

Several of the plants of this tribe or family, furniſh food both for men and quadrupeds: the chief eſculent ſorts for the kitchen-garden are pea, bean, and kidney-bean; the ſeed of which are the eatable parts, alſo the young ſeed-pods of all the kidney-bean kinds.

Many of them are alſo uſeful plants for ornamenting gardens; and for many excellent medicinal uſes; alſo many of them are valuable in various trades.

But the particular deſcription of the different genera of this order, together with their uſes and general culture, is fully illuſtrated, each under its proper head.

PAPPUS, Down of flowers, or a ſort of feathery crown, which adheres to many kinds of ſeeds, exemplified in lettuce, dandelion, ſow-thiſtle, groundſel, &c.

Many of the Pappoſe plants produce compound flowers, and their ſeeds are furniſhed with a *Pappus* adhering to the top of each, ſo as to reſemble a ſhuttle-cock, and naturally framed for flying, for the purpoſe of diſſemination or ſpreading about the ſeed, and for being tranſported by the wind to very conſiderable diſtances from its parent; an admirable contrivance of nature to ſow her productions; and thus render common to different ſoils and territories individuals of the ſame ſpecies, which without ſuch precaution might have been confined to one.

The *Pappus* is either ſimple, like hairs, *Pappos piloſus*, as in ſwallow-wort, groundſel, golden-rod, &c. or branched, or compound in a feathered like manner, *Pappus plumoſus*, as in dandelion, hemp-agrimony, ſcorzonera, and valerian: in ſome plants the *Pappus* adheres cloſe to the ſeed, *Pappus ſeſſilis*, as in hawkweed; and in ſome it is elevated upon a pedicle, or ſtipes, *Pappus ſtiptatus*, as in lettuce, dandelion, baſtard-hawkweed; and the foot-ſtalks, or threads upon which it is raiſed, have obtained the name *ſtipes*. See STIPES.

Of this tribe of Pappoſe plants are many of our moſt cumberſome weeds, the ſeeds of which by the means of the *Pappus* are diſſeminated widely about our gardens and fields, particularly groundſel, thiſtle, ſow-thiſtle, and dandelion; therefore the utmoſt care is requiſite to deſtroy all theſe kind of weeds before they perfect ſeeds.

PARASITUS *Planta*, Paraſitic Plants; plants that are produced upon the trunk or branches of other plants, and will not grow in the ground, ſuch as miſſeltoe, and numbers of the moſſes, and fungus tribe.

The manner in which Paraſitic Plants attach themſelves to others is not uniform, ſome, ſuch as the miſſeltoe, moſſes, and funguſſes, are produced originally upon the plant on which they are found growing; the former of which grows upon the branches of large trees, principally from the under ſide of the branches, extending their roots under the bark, and branch out into a large ſpreading head, which generally grows downward, in a hanging poſition; and is nouriſhed wholly at the expence of the tree upon which it grows; but the moſſes are often diſperſed all over the ſurface of the ſtem and branches; and the funguſes grow ſometimes on the upper roots of old trees, and ſometimes upon their trunk or ſtem.

Other Paraſitic Plants ariſe from the ground, and the ſtem attaches itſelf to the firſt plant it encounters, ſtrikes root therein; after which the firſt root dies, and the plant continues to live and nouriſh itſelf upon the plant on which it is fixed.

There are other ſorts of Paraſitical Plants, which rooting firſt in the ground, their ſtems attach themſelves to the bodies of trees in their neighbourhood, planting their roots into the bark, as they aſcend; continuing, however, their ground-root, and draw their principal nouriſhment from the ſoil, exemplified in the *hedera*, or ivy-tree.

PARTERRE, a ſpacious level plot of ground in the pleaſure garden, divided into many little partitions, or compartments, of different figures and dimenſions; by means of edgings or lines of dwarf-box, or by verges of graſs turf, and tracks of ſand, fine gravel, &c.

Theſe Parterre works were in great eſtimation in ancient gardening, and were commonly ſituated directly in the front of the houſe, generally the whole width of the front, and extended proportionably in length; and when the intermixture of the figures are artfully diſpoſed, they ſtrike the eye very agreeably, and afford an ornamental proſpect at all times of the year.

The general figure of a Parterre is an oblong, or long ſquare, about as long again as broad: chuſing generally a level open ſpot on ſome conſpicuous part; and in the diſtribution, there is firſt a long bed or border of earth, carried all round for a boundary; and the internal ſpace within this border, is traced out into various little partitions, or incloſures artfully diſpoſed into different figures correſponding with one another, ſuch as long ſquares, triangles, circles, various ſcroll-works, flouriſhes of embroidery, and many other devices, according to fancy; all of which figures are formed either by lines of dwarf-box, with intervening alleys and tracks of turf, ſand, fine gravel, ſmall ſhells, &c. or are formed ſometimes entirely of verges of fine turf, diſpoſed into wide or narrow compartments, as the figure may require; and ſometimes they conſiſt of box-edgings, and tracks of turf together: the partitions or beds of earth formed by the tracks of box and turf compartments, &c. are planted with ſome choice flowers; but no large plants to hide the figure of the Parterre; for the regularity of this in the artful diſtribution of the different figures, is intended as a decoration to the whole place long after the ſeaſon of the flowers is paſt.

But many prefer a Parterre compoſed entirely of turf and beds of earth, perfectly even, without any other figure than the long ſquare, forming a border of earth all round, within which is compartments of graſs, and beds or borders of earth of different dimenſions.

Sometimes Parterres, by means of box-edgings, are formed into labyrinths or mazes; and ſome are made to repreſent coats of arms with the proper ſupporters. All crowded deſigns, however, and ſuch figures as are too much compound, are to be conſidered as ſo many labyrinths, in which the eye is loſt, and therefore improper to be employed for any general plan.

Indeed Parterres in general are become in diſrepute in England, their regularity being thought too ſtiff and formal, their figures often of a trifling appearance, and their making and keeping in proper order attended with conſiderable trouble and expence, ſo that they are almoſt baniſhed the Engliſh gardens; ſubſtituting in their ſtead ſpacious graſs lawns and rural ſhrubberies.

However, a little Parterre-work for the ſake of variety, might ſtill be admitted, though not immediately in the front of the houſe, as heretofore in ancient gardening. A ſpacious lawn, bounded with a rural ſhrubbery,

bery, is the moſt eligible for that ſituation; but a plain Parterre of a moderate extent, either formed with lines of box, or with turf, might be introduced in ſome of the more internal parts, and diſtributed into plain compartments, or beds of earth for flowers, ſo as to anſwer the purpoſe of a flower-garden for the moſt curious ſorts; it will have an agreeable effect in forming a contraſt to the more rural ſcenes.

PARTING ROOTS, an expeditious mode of propagation, for the increaſe of great numbers of fibrous-rooted perennials in particular.

Great numbers of the herbaceous fibrous and tuberous-rooted perennial tribe often increaſe by the root into large cluſters or bunches, compoſed of numerous ſmall ſlips or off-ſets particularly many of our flowery perennials, illuſtrated in campanula, perennial ſun-flower, golden-rod, perennial aſters, polianthus, and daiſy, with innumerable other ſorts; which from one ſmall ſlip or off-ſet of the root often multiply in a ſeaſon or two into a large cluſter of ſuch off-ſets, and theſe cluſters of roots being parted into ſeveral ſeparate ſlips, with root-fibres at their bottom, and a bud at top, each commences a diſtinct plant; ſo that by thus Parting the Roots you may inſtantly multiply one plant into many, each of which becomes alike in growth and general habit to the original, and will all flower the enſuing ſeaſon in their due courſe; and in their turns detach from their ſides all around, a due ſupply of off-ſets for farther propagation.

The ſorts of plants that are uſually encreaſed by this mode of propagation are always exhibited in their reſpective genera under the head *Propagation*, &c.

The beſt general ſeaſon for Parting Roots is in autumn, after they have done flowering, and their ſtalks decay, which is done in September and October, and the detached off-ſets being planted directly, they will take good root before winter; though in many hardy ſorts, Parting the Roots may be performed almoſt any time, in open weather, from September till March; and ſome of the tender kinds ſucceed beſt in ſpring: obſerving, however, in Parting Roots in the ſpring-ſeaſon, it ſhould be done before they begin to ſhoot forth their ſtalks, &c.

With reſpect to the method of Parting Roots, there is nothing more eaſy: when any plant you deſign to encreaſe, has multiplied by its roots into a cluſter of off-ſets, the whole may either be taken up entirely, and the root parted into as many ſlips as are furniſhed with fibres, &c. or, on particular occaſions, a quantity of ſlips may be detached from the ſides all around as it ſtands in the ground: in either method, the work of Parting or ſlipping the Roots may in many ſorts be effected eaſily with the hand; and in many others the aſſiſtance of a knife, &c. is often neceſſary in ſeparating them properly; obſerving that when you want to make as great an increaſe as poſſible, you may part the root into as many ſlips as may be convenient, provided each is furniſhed with ſome fibre or root-part, and crowned with one or more buds or eyes for forming ſhoots at top; but when the detached off-ſets are wanted for flowering as ſtrong as poſſible the enſuing ſeaſon, they ſhould not be parted very ſmall, but into middling-ſized ſlips, where practicable, which being planted in the proper places will flower in tolerable perfection the following ſeaſon.

The ſlips ſhould generally be planted directly by dibble; the very ſmall ſlips plant in nurſery-beds to ſtand till next autumn, to acquire ſtrength; then may be tranſplanted with balls into the places where they are to remain; and the larger ſlips, may be planted as ſoon as parted, at once where they are to continue.

This method of propagation may, if thought neceſſary, be practiſed to many ſorts annually, as numbers of the herbaceous perennials multiply in one ſeaſon into large bunches, as aforeſaid, ſo as they may be encreaſed at pleaſure in great quantities.

PASSERINA, Sparrow-wort.

The plants of this genus are ſhrubby exotic ever-greens of Africa, &c. for the green-houſe collection, riſing with woody, downy, white, durable ſtalks, from about half a yard to ſix or eight feet hight high; garniſhed with ſmall fleſhy leaves; and ſmall monopetalous, tubular, four-parted flowers.

Claſs and order, *Octandria Monogynia*.

*Characters.*] CALIX, none. COROLLA, is monopetalous, with a ſlender tube, ſwelling below, and divided above into four ſpreading parts. STAMINA, eight briſtly filaments placed on the tube, and nearly oval erect antheræ. PISTILLUM, an oval germen, ſlender ſtyle, and capitated hiſpid ſtigma. PERICARPIUM, is oval, leathery, and unilocular, incloſing one oval, pointed ſeed.

[1]PASSERINA *Filiformis.*

*Filiforme-leaved Paſſerina.*] Hath a ſhrubby ſtem, branching laterally five or ſix feet high, covered with a white meally down; filiforme, or very narrow convex leaves, cloſely imbricated four ways, and at the top of the ſhoots ſmall white flowers.

This is the principal ſort in the Engliſh gardens; it is a pretty ever-green, appearing beautiful at all ſeaſons of the year.

[2]PASSERINA *Hirſuta.*

*Hirſuted, or Hairy Paſſerina.*] Hath a ſhrubby ſtalk, branching diffuſely ſix or ſeven feet high, covered with a ſoft meally down; thick, ſhort, fleſhy, imbricated leaves, ſmooth without, and downy within, and ſmall white flowers.

[3]PASSERINA *Ciliata.*

*Ciliated Paſſerina.*] Hath a ſhrubby ſtalk, branching laterally five or ſix feet high, the branches naked below; but garniſhed at top with ſpear-ſhaped, erect, ciliated leaves, and ſmall white flowers.

[4]PASSERINA *Uniflora.*

*Uniflorous Paſſerina.*] Hath a low ſhrubby ſtalk, branching out low into many ſmooth ſpreading branches, a foot and a half high; very narrow leaves placed oppoſite; and purple flowers ſingly at the termination of the branches.

Theſe exotics flower here in June and July: the flowers are ſmall, and not very conſpicuous, and are rarely ſucceeded by ſeeds in England.

The plants in this country muſt be always kept in pots of good earth, and placed in the green-houſe collection, in order for having ſhelter in winter, managing them like myrtles and others of the hardier green-houſe ſhrubs.

The propagation of all the ſorts is performed by layers and cuttings in ſpring or ſummer, giving frequent waterings, and occaſional ſhade every day to the cuttings till rooted; and by the end of September both layers and cuttings will be fit to pot off ſeparately.

PASSIFLORA, Paſſion-flower.

This genus of plants conſiſts of celebrated ſhrubby and herbaceous floriferous climbers for the pleaſure-garden, green-houſe, and ſtove; riſing moſtly with long, ſlender, cirrhoſe-climbing ſtems, aſcending by tendrils many feet high; ornamented ſome with palmated many-lobed leaves, others are bilobed, trilobed, multilobed, &c. and ſome with entire leaves; and at the axillas large pentapetalous nectariferous, ſpreading flowers, of ſingularly curious ſtructure and beauty.

Claſs and order, *Gynandria Pentandria.*

*Characters.*] CALIX, is five-lobed, plane and coloured. COROLLA, five large half-ſpear-ſhaped, plane, obtuſe petals, the ſize and figure of the calix, and a nectarium within the petals, formed of many fibres or rays, in a ſort of triple coronet round the ſtyle, the exterior ones longeſt, and the upper ones drawing in narrow above. STAMINA, five awl-ſhaped gynandrous filaments, they being attached to a ſort of pillar crowned by the germen, and are placed at its baſe, ſpread out every way, and terminated by oblong incumbent antheræ. PISTILLUM, a roundiſh germen elevated upon an erect pillar or column, and the germen ſupporting three ſpreading ſtyles, crowned each with a capitated ſtigma. PERICARPIUM, an oval, fleſhy, baccaceous, unilocular fruit, placed on a pedicle, and many oval ſeeds.

There are near thirty different ſpecies, but ſcarce one third of that number common to the Engliſh gardens; all of which are natives of foreign warm countries, in different parts of the world; and only one of them is hardy enough to ſucceed well here in the open ground; the others requiring ſhelter of a green-houſe and ſtove, but moſtly of the latter.

*Hardy Kind for the full Ground.*

There is only one hardy ſpecies, a ſhrubby exotic from the the Brazils, which will proſper here in the full ground, planted againſt a warm ſouth wall, where it will produce flowers and fruit annually; the flowers have ſingular beauty, but the fruit is only for variety as it grows, and for its ſeed for propagation.

[1]PASSIFLORA *Cærulæ.*

*Blue-rayed Common Palmated Paſſion-flower.*] Hath long, ſlender, ſhrubby, cirrhoſe-climbing, purpleiſh-green ſtalks, branchy and aſcending upon ſupport by their claſpers thirty or forty-feet high; having at each joint one large palmated leaf, of five long folioles expanding like an open hand, accompanied at the ſame joint by a long twining *cirrhi*, or claſper; and at the axillas large ſpreading flowers, with whitiſh-green petals, and a blue radiated nectarium; ſucceeded by a large, oval, yellowiſh fruit.

It flowers from July until October; the flowers are very large, conſpicuous, and their compoſition is exceedingly curious and beautiful.

The general ſtructure of the ſingular flowers of this plant is, they come out at the axillas on pedunculi about three inches long, which they terminate, each flower having juſt cloſe under the calix a three-lobed involucrum-like appendage; a five-lobed calix, and a five-petalous corolla, the ſize, figure, and colour of the calix, &c. the petals arranging alternately with the calicinal lobes, the whole, including the involucrum, calix, and corolla, make juſt thirteen lobes and petals, all expanded flat; and within the corolla is the nectarium compoſed of a multitude of thread-like fibres, of a blue and purple colour, diſpoſed in circular rays round the column of the fructification, the outer ray is the longeſt, flat and ſpreading on the petals; the inner is ſhort, erect, and narrows towards the centre; in the middle is an erect cylindric club-ſhaped column, or pillar, crowned with the roundiſh germen, having at its baſe five horizontal ſpreading filaments, crowned with incumbent yellow antheræ, that move about every way; and from the ſide of the germen ariſes three ſlender ſpreading ſtyles, terminated by headed ſtigmas; the germen afterwards gradually becomes a large oval fleſhy fruit, ripening to a yellowiſh colour.

Theſe wonderful flowers are only of one days duration, generally opening about eleven or twelve o'clock, and frequently in hot ſunny weather burſt open with elaſticity, and continue fully expanded all that day, and the next they gradually cloſe, aſſuming a decayed-like appearance, and never open any more; the evening puts a period to their exiſtence, but are ſucceeded by new ones daily on the ſame plant.

This plant and flowers are held in great veneration in ſome foreign catholic countries, where the religious make the leaves, tendrils, and different parts of the flower to repreſent the inſtruments of our bleſſed Saviour's paſſion; hence the name *Paſſiflora*.

### *Green-houſe Kinds.*

There are two herbaceous ſpecies, exotics of Virginia and other parts of America, that will proſper here in the open air, ſometimes the year round in a warm ſituation; but are always ſubject to injury from ſevere froſt, therefore it is proper to keep them principally in pots, in order to move to ſhelter of a green-houſe in winter.

Both the ſorts have abiding roots, but the ſtalks generally decay here in winter, and are renewed again in ſpring.

[2]PASSIFLORA *Incarnata.*

*Incarnated, or Fleſh-coloured Italian Paſſion-flower.*] Hath a ſtrong perennial root; ſlender, herbaceous, cirrhoſe-climbing ſtalks, riſing upon ſupport four or five feet high; leaves compoſed of three ſawed lobes, each leaf attended by a twining tendril; and at the axillas long ſlender pedunculi, terminated each by one whitiſh flower, having a greeniſh calix, and a reddiſh, or purple radiated nectarium, ſurrounding the column of the fructification, which ſucceed to a large, round, fleſhy fruit, ripening to a beautiful orange colour.

The flowers of this ſpecies are alſo very beautiful, though of ſhort duration, opening in the morning, and night puts a period to their beauty; but are ſucceeded by a daily ſupply of new ones.

The fruit of this ſort is alſo very ornamental, as ripening to a fine reddiſh orange colour; but theſe rarely attain perfection here, unleſs the plants are placed in the ſtove, therefore when there is ſuch accommodation, it highly merits that indulgence, where it will exhibit both flowers and green and ripe fruit, all at the ſame time in a beautiful manner. Remarking, however, it will flower in the open air freely in ſummer, but not perfect its fruit, ſo as to appear ſo ornamental, as with the indulgence of a ſtove.

[3]PASSIFLORA *Lutea.*

*Yellow Virginian Paſſion-flower.*] Hath a creeping perennial root; weak, ſlender, herbaceous, cirrhoſe-climbing ſtalks, riſing upon ſupport, three or four feet high; heart-ſhaped, three-lobed, ſmooth leaves, having three equal, obtuſe, entire lobes; each leaf attended by a twining claſper; and ſhortiſh pedunculi ſuſtaining ſmall yellowiſh flowers.

Some of both theſe ſpecies ſhould always be retained in pots for removing them under ſhelter of a green-houſe or garden-frame in winter, to have protection from froſt; and ſome may be planted in a dry warm ſituation againſt a ſouth wall, where they will live thro' our moderate winters, but are liable to ſuffer in ſevere froſts, unleſs they are covered.

*Stove.*

*Stove Kinds.*

The *Paſſifloras* of this temperature are exotics of South America and other hot parts of the world, and require the ſhelter of a ſtove here, and of which the following are the principal ſorts in our garden; ſome of them have undivided leaves, others are bilobate, and trilobate, &c.

[4]PASSIFLORA *Serratifolia.*

*Sawed-leaved Surinam Paſſion-flower.*] Hath ſlender, angular ſtalks, climbing by the tendrils ſeveral feet high; undivided, oblong-lanceolate leaves, ſerrated on the edges, accompanied by twining cirrhi; and axillary reddiſh-green flowers.

[5]PASSIFLORA *Laurifolia.*

*Laurus-leaved Paſſion-flower.*] Hath long, tough, rough, branchy, cirrhoſe-climbing ſtalks, riſing by ſupport twenty or thirty feet high; undivided, oval, thick, entire leaves, on biglandulous foot ſtalks; and axillary ſnowy white flowers, ſtriped or ſpotted with red, blue, and yellow, and with violet-coloured rays, a yellow column, purple ſtyles, and indented involucrum.

[6]PASSIFLORA *Veſpertilio.*

*Veſpertilious-leaved, or Bat's-wing Paſſion-flower.*] Hath ſlender, ſtriated, branchy ſtalks; large, bilobate or two-lobed leaves, the baſe roundiſh and glandular, the lobes acute, widely divaricated like a bat's wings, and dotted underneath; and axillary flowers, having white petals and rays.

The leaves of this ſpecies have a ſingular appearance, the two lobes being expanded ſix or ſeven inches wide, reſembling the wings of a bat upon flight; hence the name *Veſpertilio.*

[7]PASSIFLORA *Rubra.*

*Red Paſſion-flower.*] Hath roundiſh or angular ſtalks; bilobate, heart-ſhaped acuminated leaves; and red flowers, ſucceeded by an hexagonal ſcarlet fruit.

[8]PASSIFLORA *Maliformis.*

*Apple-fruited Paſſion flower.*] Hath long, thick, triangular, cirrhoſe-climbing ſtems, riſing by ſupport fifteen or twenty feet high; undivided, large, oblong-heart-ſhaped, entire leaves, on biglandular or two-eared foot-ſtalks; and long axillary peduncules, ſuſtaining large, white-petalous flowers, having reddiſh entire involucrums, and purpeliſh rays, ſucceeded by large maliforme, or apple-ſhaped yellow fruit.

[9]PASSIFLORA *Holoſerea.*

*Silky-leaved Paſſion-flower.*] Hath long, ſlender, downy ſtalks, climbing by ſupport twenty feet high; three-lobed halbert-ſhaped, downy, ſoft, ſilky leaves; having each ſide of the baſe indented and reflexed; and axillary white flowers, with purple and yellow rays.

[10]PASSIFLORA *Multiflora.*

*Multiflorous, Paſſion flower.*] Hath long, ſlender, cirrhoſe-climbing ſtalks, riſing by ſupport twenty feet high; undivided, oblong, entire leaves; and flowers growing in cluſters, having white petals and purple rays; ſucceeded by ſmalliſh, egg-ſhaped, yellow fruit.

[11]PASSIFLORA *Quadrangularis.*

*Quadrangular-ſtalked Paſſion-flower.*] Hath long, four-cornered, membraneous ſtalks, climbing many feet high; undivided, almoſt heart-ſhaped entire leaves, on foot-ſtalks having ſix glands; and large white and purple flowers.

[12]PASSIFLORA *Suberoſa.*

*Cork-barked Paſſion-flower.*] Hath ſlender ſtalks, climbing fifteen or twenty feet high, having a whitiſh, fungus, cracked bark, like the cork-tree; three-lobed, target-ſhaped leaves; and ſmall whitiſh-green flowers.

All theſe ſpecies of *Paſſiflora* flower here in ſummer, beginning commonly in July, and continue in ſucceſſion for two or three months; for although the flowers of all the ſorts are ſcarcely of more than one day's duration, they are ſucceeded by new ones daily, for as the ſhoots advance, freſh flowers ariſe at the joints; in all the ſorts they conſiſt each of a five-lobed calix, and a corolla of five petals, and circular rays in the centre, ſurrounding the column of the fructification (ſee the *Characters*); and many of the ſorts are ſucceeded by fruit in our gardens, which in all the ſorts is of an oval form, ſome of the ſize of large plums and middling apples, and ſome not larger than gooſeberries.

All the twelve ſpecies here enumerated, are of the cirrhoſe-climbing kind, i. e. climbing by means of their twining *cirrhi*, or claſpers, that catch hold of any adjacent ſupport. See CLIMBING PLANTS.

As all the ſpecies are natives of warm countries, in theſe parts they are moſtly of a tender quality, except the firſt ſort, which ſucceeds very well in the full ground, in a warm ſitu-

ſituation; only their young branches are ſometimes killed in very ſevere winters; but plenty of new ones generally riſe again in ſpring following: the ſecond and third ſorts, however, are tender, and muſt, for the moſt part, have ſhelter in winter: all the others, denominated ſtove kinds, muſt always be retained in that repoſitory.

The firſt ſpecies, *Paſſiflora Cærulæ*, being the hardieſt, is conſiderably the moſt common ſort in our gardens; is ſuperior both as a climber, and in the beauty of its flowers: as a climber it demands our particular notice, for it may be trained to the top of the higheſt walls, even if thirty or forty feet high, and will often ſhoot fifteen or twenty feet in one ſeaſon; producing from the joints as they advance, a plentiful ſucceſſion of their extraordinary flowers for three months; therefore this fine climber highly merits a place in every garden; and may be eaſily raiſed from ſeed, layers, and cuttings (ſee its *Propagation*); or may be purchaſed reaſonable at all the nurſeries. The ſeaſon for tranſplanting it is early in autumn, or in February or March.

It ſhould generally be planted againſt ſome high warm wall, in order for training its branches, for they muſt be ſupported, otherwiſe they will trail on the ground, or entangle with one another, ſo that its ſtems and branches muſt be conſtantly nailed up to the wall five or ſix inches aſunder; and according as they ſhoot during ſummer, train in moſt of the ſhoots for flowering, and principally at full length for the preſent, ſuffering them to remain ſo all the winter; and in ſpring the whole may be pruned, cutting out all dead ſhoots that have been killed by the froſt, and where the branches or ſhoots are too much crowded, thin out all the weakeſt and worſt placed; leaving a due ſupply of the ſtrongeſt ſhoots at proper diſtances in every part from bottom to top, and let each of thoſe be ſhortened to about a yard, or four or five feet long, according to their ſtrength, both to confine them within proper compaſs, if neceſſary, and promote their throwing out ſtrong ſhoots for the enſuing ſummer's bloom, for the flowers are produced always upon the ſhoots of the year.

As in ſevere winters their branches, if not protected, are ſometimes killed, it is adviſable at ſuch times, whilſt the plants are young in particular, to grant them ſhelter of mats during the inclement ſeaſon, and protect their roots with dry litter laid over the ground: obſerving, however, to uncover their branches as ſoon as the froſt breaks: this covering, however, is only neceſſary in very ſevere froſts.

The two green-houſe ſorts ſhould generally be potted, to move to ſhelter in winter, either of a green-houſe or garden-frame: ſome plants of each ſort may alſo be planted in the full ground, in a warm border, to take their chance; obſerving to cover the ground over their roots in ſevere weather; obſerving in both methods to place ſtakes in ſummer to train the ſtems and branches upon.

All the ſtove kinds muſt conſtantly be kept in pots, placed always in the ſtove, and for the moſt part plunged in the bark-bed; placing ſtrong ſtakes for the purpoſe of training the branches; managing them as other ſtove-plants of a ſimilar nature. See STOVE-PLANTS.

*Propagation, of all the Sorts.*

The propagation of all theſe ſpecies of *Paſſiflora* is, by ſeed, by layers, and by cuttings; under the following heads, hardy kind, green-houſe kinds, and ſtove kinds.

Hardy Kind.—This ſort, common Paſſion-flower, is raiſed in the three following ways. Firſt, by ſeed: in March ſow the ſeed in large pots, half an inch deep, and either plunge them in a warm border, and as the weather becomes warm move them to the ſhade; or if as ſoon as the ſeed is ſowed, the pots are plunged in a hot-bed, it will forward the germination of the ſeed, and the plants will riſe ſooner; which harden gradually to the open air till october; then place them under a garden-frame for the winter, to have ſhelter from froſts, and in ſpring plant them out in nurſery-rows, and in a year or two they may be tranſplanted where they are to remain, againſt ſome warm ſouth wall. 2. By layers: in ſpring lay down ſome of the branches in the common way, they will readily emit roots, and make proper plants by autumn; when, or rather in ſpring following, tranſplant them either in nurſery rows, or where they are to remain. 3. By cuttings: in February or March cut off a quantity of ſtrong young ſhoots, in length of from about eight to ten or twelve inches, plant them in any bed or border of common earth, giving frequent watering in dry weather, and when ſunny and hot, a moderate ſhade of mats will be of much advantage, and they will emit roots at bottom, and ſhoots at top, and become good plants by autumn, allow-

allowing them occaſional ſhelter of mats, &c. during the winter's froſt, and in ſpring plant them out.

If a quantity of theſe cuttings are planted cloſe, and covered down with hand-glaſſes, it will forward their rooting; obſerving, however, when they begin to ſhoot at top, to remove the glaſſes.

Green-houſe Kinds.—Both the ſorts, by ſeeds, layers, and parting the roots. 1. By ſeed. This is commonly obtained from America; ſow it in pots in March, and plunge them in a hot-bed to raiſe the plants, which inure to the open air in ſummer, and give them ſhelter of a green-houſe or frame in winter, and in ſpring plant ſome out in pots, and place them among the green-houſe and other plants in the full ground, under a warm fence to take their chance. 2. By layers. In ſpring lay ſome young ſhoots; they will readily grow and become good plants for potting off in autumn. 3. By parting the roots. In ſpring, before they begin to ſhoot, is the proper time; the ſecond ſort in particular multiplies exceedingly by its creeping roots; which divide into ſlips, and plant them in a bed of rich earth till autumn, when ſome ſhould be tranſplanted into pots for occaſional ſhelter in winter.

Stove Kinds.——All theſe ſorts by ſeed, layers, and cuttings.

By Seed.—This is procured chiefly from abroad; ſow it in ſpring in pots, plunge them in a hot-bed, or in a ſtove bark-bed; the plants will ſoon appear, which, when three inches high, prick out in ſeparate ſmall pots, give water and plunge them again in the hot-bed, giving occaſional ſhade till rooted; as they advance in growth ſhift them into larger pots, and retain them conſtantly in the ſtove.

By Layers.——In ſpring, or beginning of ſummer, lay the young branches, they will readily grow, and be fit to pot off ſeparately in autumn.

By Cuttings.—In ſpring or ſummer plant ſome cuttings of the young ſhoots in pots, plunge them in the bark-bed, give water frequently; moſt of them will take root, and be fit to pot off ſingly in autumn.

PASTINACA, Parſnep.

The principal of this genus is that well known herbaceous eſculent, *Garden Parſnep*, a biennial of high eſtimation for its large eatable root, valuable for winter and ſpring ſervice, crowned with large pinnated leaves, and umbelliferous flowers.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, multiple umbelliferous flowers, deſtitute of an involucrum, and with ſcarcely viſible cups to the florets. COROLLA, a uniform umbel of many ſmall florets, compoſed each of five ſpear-ſhaped involute petals. STAMINA, five hair-like filaments, and roundiſh antheræ. PISTILLUM, a ſmall germen under each floret, two reflexed ſtyles, and obtuſe ſtigmas. PERICARPIUM, none, a plane compreſſed eliptical, two-parted fruit, having two eliptic ſeeds, ſurrounded with a border.

There are only two ſpecies of this genus, the principal of which for our purpoſe is the common parſnep, viz.

PASTINACA *Sativa.*

*Cultivated, or Garden Parſnep.*] Hath a large, long, fleſhy root, penetrating perpendicularly into the ground, half a yard or two feet in length, three or four inches or more thick at top, tapering gradually to the lower end; crowned with very large ſingly-pinnated leaves; and when it ſhoots for ſeed, riſes with an upright, ſtrong, channelled, hairy ſtalk, branching four or five feet high, having all the branches terminated by large yellow umbels of flowers.

*Variety.*] Wild Parſnep with hairy leaves.

They are biennial plants, that being raiſed from ſeed in ſpring, ſhoot up only leaves the firſt ſummer, and the roots attain perfection for uſe the ſucceeding autumn and winter; and in the ſpring after they ſhoot up into ſtalk for flower and ſeed, and having ripened ſeed, totally periſh; ſo that a freſh ſupply muſt be raiſed annually.

The Garden Parſnep is an exceeding fine eſculent root, though by reaſon of its peculiar ſweet reliſh, it is not in general eſtimation; it, however, is a very wholeſome and nouriſhing root, to many very palatable, and is very profitable for family ſervice, and goes off well in the markets.

The principal ſeaſon of parſneps is from October or November until March; for they are ſeldom good till they have attained their full growth, determinable by their leaves beginning to turn yellow and decay in autumn; and they will continue in great perfection until March or April, that they begin to ſhoot up into ſtalk for ſeed, when they become hard, ſticky, and unfit for eating.

In

*Its Propagation and Culture.*

The propagation of this eſculent root is by ſeed annually in the open quarters of the kitchen garden. February and March is the proper ſeaſon for ſowing. Obſerving to procure freſh ſeed, for if more than one year old, it will not grow.

I ſhould adviſe the main crop of Parſneps to be ſowed alone, and not mixed with other crops, ſuch as onions, leeks, or carrots, as often practiſed, for there is nothing gained by this, it rather cauſes confuſion, and more trouble in the culture; but by ſowing them ſeparate, their culture can be more regularly attended to, and the crop will attain greater perfection.

Chuſe for this crop a ſpot of light, rich, deep ſoil, in one of the moſt open airy quarters, which ſhould be trenched one full ſpade deep at leaſt, or if two the better, provided the depth of good ſtaple admit, that the roots may have a due depth of looſe ſoil to run down to their full length: obſerving, that if the ground is previouſly trenched up in rough ridges in winter, eſpecially if any ways ſtiff or wet, and let it lie expoſed ſome time to the ſun and air, it will improve its temperament greatly for this purpoſe; then at ſowing time level it down, in dry weather, for the reception of the ſeed, breaking all large clods, and leave an even ſurface, but not rake it till after the ſeed is ſowed, which ſhould generally be performed whilſt the ground is freſh ſtirred, or at leaſt before the ſurface becomes too dry, ſo as in raking the clods will readily fall under the rake to bury the ſeed regularly.

Sow the ſeed by broad-caſt thinly, either all over the ſurface, or the ground may be divided into four-feet wide beds, as ſhall be convenient, though for large quantities the former is the moſt eligible practice; as ſoon as the ſowing is done, tread down the ſeeds evenly, and finiſh with an even raking, to cover all the ſeeds equally, and to ſmooth the ſurface: in about three weeks, or a little more or leſs time, the ſeeds will germinate, and the plants will appear above ground, when they ſhould be thinned and weeded as directed below.

When the plants are two or three inches high, proceed to thin them to regular diſtances, and clean them from weeds; which works ſhould generally be performed by a three or four-inch hoe; chuſe dry weather, and cut out the plants to about ten or twelve inches diſtance, for they ſhould have large room, cutting up all weeds as you proceed; after this no more culture will be required till the future progreſs of the weeds render another hoeing neceſſary; and probably another repetition may alſo be required, till the plants are in full leaf, when they will cover the ground, and bid defiance to any farther interruption from weeds, and will not require any farther attention till autumn, when the roots will become fit for uſe.

In October the roots will be arrived nearly at full growth; when the leaves begin to turn yellow and decay, is a certain ſign of maturity, and may then begin to dig up ſome of them for uſe, according as they are wanted.

Theſe roots may either remain in the ground all winter, and be taken up according as they are wanted; or may be dug up in November, and their tops pared off cloſe, then buried all winter in ſand, in ſome ſhed or other dry place, to be ready at all times for uſe, as directed for carrots, which may be practicable enough for ſmall quantities: you may leave ſome, however, in the ground for ſpring ſervice, till January or the beginning of February, juſt before they begin to ſhoot, then dig them up and lay them in ſand; and by taking them up at this time, it will retard their effort for ſhooting, ſo as they will continue in tolerable perfection until the latter end of April.

Parſneps when raiſed for ſale generally make a tolerably profitable crop, particularly about London, where they are always ready ſale, from November ill April. In preparing them for market, they pare off the top quite cloſe, and trim the lower end, and waſh them clean; then bunch them up with oſier rods, in flat bunches, ſix or more roots in each, according to their ſize: thus prepared they are ſold in market to the retailers at from two or three to four or five ſhillings per dozen of bunches.

*Saving Seeds of this Plant.*

To have parſneps always in due perfection, great care is neceſſary to ſave ſeed only from ſome of the fineſt roots.

Therefore in autumn or November ſelect a quantity of the large, long, ſtraight roots, trim off their leaves, and plant them in rows three feet aſunder, two diſtant in the lines, and about an inch deep over their top;

thus they will ſhoot up ſtrong in ſpring for flowering, and will ripen ſeed in the latter end of Auguſt, or early in September; when in dry days cut off the umbels of ſeed, and ſpread them upon mats to dry and harden, then thraſh out the ſeeds, and put them up in bags for ſowing next ſpring.

PEDICELLUS, Pedicle, a partial flower-ſtalk, or proper ſtalk of any ſingle flower of an aggregate or cluſter of flowers; the main flower-ſtalk which proceeds immediately from the plant, and ſupports one, two or many flowers, is termed the *Pedunculus*, or common foot-ſtalk of the flowers; and all the leſſer ſtalks detached from the ſides or any part of this, are by Linnæus ſtyled *Pedicellus*. See PEDUNCULUS.

PEDUNCULUS, Peduncle, the main foot-ſtalk of a flower, or head of flowers, bearing the fructification only, and not the leaves.

The Peduncle is often divided or branched into others, and each of the diviſions is termed a *Pedicellus*, or little flower-ſtalk; ſo that the principal foot-ſtalk of any head or cluſter of flowers, is ſtyled the common flower-ſtalk or *Pedunculi*; each of the leſſer foot-ſtalks iſſuing from it is the partial ſtalk, or pedicle, of any ſingle flower in the aggregate, head, or cluſter of flowers, ſupported by the main foot-ſtalk, or Peduncle; thus the *Pedicellus* is always diſtinguiſhable from the main flower-ſtalk, or *Pedunculus*. See PEDICELLUS.

The Pedunculi, or main flower-ſtalks, are alſo diſtinguiſhed by different epithets, according to the place of the plant from which they proceed, as the root, ſtem, branch, axillas, termination, &c. viz.

*Pedunculus radicalis*, radical, or root flower-ſtalk, riſing immediately from the root.

*Pedunculus caulinus*, cauline, or ſtem-flower-ſtalk; when it proceeds from the ſtem.

*Pedunculus rameus*, ramous, or branch-flower-ſtalk; when it proceeds from the branches.

*Pedunculus axillaris*, axillary, or boſom-flower-ſtalk; when it proceeds from the axilla, i. e. comes out at the angles between the leaf and ſtem, or branch, or between the branch and ſtem. See AXILLA.

*Pedunculus terminalis*, terminal-flower-ſtalk; when it proceeds from the termination or end of the ſtem or branch.

*Pedunculus ſolitaris*, ſolitary Peduncle; when it grows ſingly, or only one in the ſame place. Remarking that a ſolitary Peduncule may ſupport many flowers; but a ſolitary flower implies a ſingle or ſolitary flower-ſtalk.

*Pedunculi ſparſis*, ſparſid, or ſcattered-flower-ſtalks; when they grow many together, ſcattered without any order.

Laſtly, the Peduncule bears other different epithets, both from the number of flowers on each, and from the different modes in which the flowers are borne and connected on the Peduncule, &c.

To expreſs the number of flowers on each Peduncule, they are called *uniflorous* when they bear but one flower; *biflorus* when two flowers; *triflorus*, when three flowers; and *multiflorous* when many flowers.

And to expreſs the different principal modes of bearing the flowers, they are termed either *capitulum*, i. e. little head, or compact round cluſter; *ſpica*, the ſpike; *corymbus*, a corymbous; *umbellata*, an umbel; *panicula*, the panicle; *thyrſus*, the thyrſe; *racemus*, a cluſter; *verticillus*, the verticilli, or whorled-ſpiked. See each under its reſpective head.

To the above modes of flowering may alſo be added: *aggregatus*, the aggregate; *amentaceus*, the amentum; and *ſpadiceus*, the ſpadix. See AGGREGATUS, AMENTACEUS, and SPADICEUS.

PENDULUS *Flos*, Pendulous flowers; ſuch as hang downward in a looſe dangling manner.

PENTANDRIA, the name of the fifth claſs; conſiſting of plants with hermaphrodite flowers, having five ſtamina, and compriſes ſix orders derived from the number of ſtyles. See CLASSIS.

PENTAPETALI, Pentapetalous, or five petals; flowers that have five petals. See COROLLA.

PERENNIS *Plantaris*, Perennial, or everlaſting plants; plants that are perpetuated by the roots, that is, whether their leaves and ſtalks decay annually in winter, or always remain, provided the roots are of ſeveral years duration, they are ſtill Perennial plants.

All plants, therefore, with abiding roots, both of the herbaceous tribe in general, and of the ſhrub and tree kinds are Perennials; though in the general acceptation of the word Perennial, it is moſt commonly applied to herbaceous vegetables with durable roots, more eſpecially thoſe of the flowery kind, which among gardeners are commonly called ſimply Perennials, particularly the fibrous-rooted tribe; but it is equally applicable to fibrous, tube-

tuberous, and bulbous-rooted plants, whoſe roots are of ſeveral years duration: likewiſe all ſhrubs and trees of every denomination, as having abiding roots, are alſo Perennial plants.

Perennial plants conſiſt both of deciduous and ever-green kinds; thoſe that caſt their leaves, &c. in winter are termed deciduous Perennials, and thoſe which retain their leaves ever-greens.

Of the herbaceous Perennials, however, both of the fibrous-rooted tribe, tuberous and bulbous-rooted kinds, far the greater part have annual ſtalks, riſing in ſpring and decay in winter; and a great many loſe their leaves entirely alſo in that ſeaſon, ſuch as the Perennial ſun-flower, aſters, and numerous other ſorts; and many ſorts retain their leaves all the year, but not their ſtalks, exemplified in the auricula, polyanthus, ſome *campanulas*, pinks, carnations, and many others.

Great numbers of the herbaceous Perennials multiply exceedingly by off-ſets of the root, by which they are propagated in great abundance. See OFF-SETS and PARTING ROOTS.

All the tree and ſhrub Perennials are durable both in root, ſtem, and branch; but all renew their leaves annually, even the ever-green kinds, although they are in leaf the year round, yet they put forth new leaves every year, to which the old ones gradually give place.

PERIANTHIUM, flower-cup, or the moſt common ſpecies of calix, placed immediately under the corolla, containing it as in a cup. See CALIX.

Many flowers, however, are deſtitute of a *Perianthium*, or flower-cup, ſuch as moſt of the liliaceous plants, as the lily, tulip, crown-imperial, &c.

But far the greater number of plants are furniſhed with a proper flower-cup, and is of different ſtructures in different genera: for ſome explanation, ſee CALIX.

PERICARPIUM, the ſeed-veſſel of plants, analogous to the fecundating ovary in animals; and is formed of the germen, or ſeed-bud in the centre of the flower; which when fertilized by the male-duſt of the antheræ, it then, and not before, becomes a *Pericarpium*, pregnant with ſeed, and gradually ſwells to maturity, and the ſeed ripens accordingly. See GERMEN and SEMEN.

All plants, however, are not furniſhed with a *Pericarpium*; in default of which, either the recepatcle or calix performs that function, by incloſing the ſeeds and accompanying them to maturity.

A *Pericarpium* compriſes different ſpecies or ſorts of ſeed-veſſels, as follows:

CAPSULA, capſule; a dry hollow ſeed-veſſel, that naturally cleaves or ſeparates in ſome determinate manner in one, two, three, or more valves, or openings, for diſperſing the ſeeds; ſo have often from one or two to many valves, as well as loculi, or ſeed cells, as hereafter hinted. See alſo CAPSULA.

LEGUMEN, a legum or pod; a ſeed-veſſel that has two valves or openings, incloſing a number of ſeeds faſtened along one future or ſeam only, ſuch as the pea, bean, &c. See LEGUMEN.

SILIQUA, a ſeed-pod, with two valves, having the ſeeds attached alternately to both ſutures, or joining of the valves, as in cabbage, turnep, wall-flower, ſtock-gilliflower, &c. See SILIQUA.

FOLLICULUS; having only one valve, opening from bottom to top, and having the ſeeds attached to a receptacle within.

DRUPA, a ſtone fruit, of a fleſhy or pulpy nature, without any valve or external opening, and contains a ſtone or nut; the cherry, plum, peach, and moſt other ſtone fruit, are all Drupaceous ſeed-veſſels.

BACCA, a berry; a pulpy fruit without a valve, incloſing a number of ſeeds; as in the currant, gooſeberry, ſtrawberry, &c. See BACCA.

POMUM, apple; a fleſhy fruit of the apple-kind, without any valve or external opening; having in the middle a membranous capſule of ſeveral cells, containing the ſeeds. See POMUM.

STROBILUS, a ſcaly fruit of the cone-kind; being compoſed of a number of woody ſcales, exemplified in the cones of the *Pinus*, fir-tree, &c. See CONUS, and STROBILUS.

Each of the above ſpecies of *Pericarpium*, although of a peculiar ſtructure, yet the ſame ſort is often of different figures and magnitudes in different genera, as is expreſſed in their reſpective *Characters*; as oblong, oval, roundiſh, conical, and various other ſhapes; and ſome *Pericarpiums* having from one or two to many valves or openings, particularly the capſule-kind, which, when of one valve, is termed an *univalvular*, or one-valved *Pericarpium*; of two valves, *bivalvular*; of three, *trivalvular*; of four, *quadrivalvular*; of five, *quin-*

*quevalvular*; of many valves, *multivalvular*. Likewiſe different *Pericarpiums* have from one or two to many *loculi*, cells or lodgments of the ſeeds; ſo that when of one *loculi* or cell, it is termed an *unilocular Pericarpium*; of two cells, *bilocular*; of three, *trilocular*; of four, *quadrilocular*; of five, *quinquelocular*; and of many cells, *multilocular*, &c. all of which is fully exhibited as they occur in diſcriminating the *Characters* of their reſpective genera, for the *Pericarpium* is always employed as an eſſential diſtinction in each genus; and is likewiſe often uſed as a deſcriptive mark in diſtinguiſhing the ſpecies in many genera.

With reſpect to the ſeeds, relative to their number, figure, ſize, &c. in the *Pericarpium*, it is very different in different genera; as in point of number, they are from one to many hundreds; and their figure and ſize are alſo exceedingly various, as is expreſſed in the *Characters* of each genera, &c. See alſo SEMEN.

PERIPLOCA, Climbing Dog's-bane, or Virginian Silk.

It conſiſts of ligneous, volibilate-climbing exotics for the ſhrubbery, green-houſe, and ſtove, riſing with twining ſtalks about any ſupport many feet high; garniſhed with oval-oblong and heart-ſhaped entire leaves, and monopetalous wheel-ſhaped, five-parted flowers in cluſters.

Claſs and order, *Pentandria Digynia*.

*Characters.*] CALIX, is five-parted and permanent. COROLLA, is a monopetalous, rotated, plane, and divided into five narrow ſegments, and with a very ſmall nectarium ſurrounding the centre of the corolla. STAMINA, five ſhort incurved filaments, and erect antheræ. PISTILLUM, a bifid germen, two cylindric ſtyles, and headed ſtigmas. PERICARPIUM, two large, oblong, ventricoſe, unilocular follicules, filled with numerous imbricated ſeeds crowned with down.

There are but three or four ſpecies, all exotics from diſtant countries, of which one is hardy for the ſhrubbery, one for the green-houſe, and the other for the ſtove.

[1]PERIPLOCA *Græca*.

*Grecian Periploca, or Common Climbing Dog's-bane.*] Hath ſhrubby, long, volibilate-climbing, branchy ſtalks, winding round any ſupport thirty or forty feet high; large, oblong-ſpear-ſhape leaves, oppoſite by pairs, of a ſhining-green above, and whitiſh underneath; and at the axillas towards the ends of the ſhoots ſmall cluſters of purple flowers, hairy within.

[2]PERIPLOCA *Africana*.

*African Hairy-ſtalked Periploca.*] Hath ligneous twining, hairy ſtalks, riſing upon ſupport near three feet high; oval hairy leaves, by oppoſite pairs; and from the ſides of the branches ſmall cluſters of purpleiſh flowers.

*Varieties.*] Smooth-ſtalked African *Periploca*—ſinuated-leaved.

[3]PERIPLOCA *Indica*.

*Indian Periploca.*] Hath ſhrubby, ſlender, volibilate-climbing ſtalks, riſing by ſupport ſeveral feet high; oval-ſpear-ſhaped, ſmooth leaves; and flowers in imbricated ſpikes of different colours in the varieties.

Theſe three plants flower principally in July and Auguſt, generally in ſmall bunches; each ſeparate flower is of one plane petal, cut into five ſegments; but are rarely ſucceeded by ſeeds in England.

Theſe plants are retained in many of our gardens, to add to the variety of climbers.

The firſt ſort in particular is a fine volibilate-climbing plant for the ſhrubbery. It will readily wind its ſtalks and branches round any adjacent tree, hedge, pole, or any thing it encounters in its progreſs, and riſe to a prodigious height; and in default of any neighbouring ſupport it will twine and entangle its branches round one another in a complicated manner; but it ſhould generally be allowed ſupport, and it will ſhew itſelf to much greater advantage.

The ſecond and third ſpecies ſhould always be kept in pots, placing the former among the green-houſe exotics to have ſhelter in winter; and the latter placed always in the ſtove.

The propagation of all the ſorts is eaſily effected by layers, which if layed in the ſpring, or early in ſummer, they will be rooted ſufficiently by autumn, and may then be tranſplanted; the hardy kind into the nurſery, the others in pots.

Cuttings of the firſt ſort will alſo often ſucceed; likewiſe of the other two, by aid of a hot-bed.

They may alſo all be raiſed from ſeed procured from abroad; which ſhould be ſowed in ſpring in pots, and plunged in a hot-bed, eſpecially of the ſecond and third ſorts.

PETALUM, Petal, the fine coloured leaves of the flower, which form the *Corolla*. See COROLLA.

PETIOLUS, the foot-ſtalk of the leaves only, very different from the *Pedunculus*, the foot-ſtalk of the flowers; for it is in very few inſtances that either the ſame *Petiolus*, or *Pedunculus*, ſupport both leaves and flowers; Linnæus, therefore, has very properly marked their diſtinction by aſſigning each a different name.

The *Petiolus*, or foot-ſtalk of the leaves, is very commonly furniſhed with two diſtinct ſurfaces, a front and a back; the former flat, the latter round.

Some leaves, however, have no foot-ſtalks at all, but are cloſe-ſitting, or *ſeſſile*. See FOLIUM.

PHASEOLUS, Kidney-bean.

This noted genus conſiſts principally of herbaceous annuals; one ſpecies of which, *common Kidney-bean*, is the chief, and is a moſt valuable legumenous vegetable, compriſing many excellent varieties, both dwarf-growers and high-climbers; garniſhed univerſally with trifoliate leaves, and papilionaceous hermaphrodite flowers, ſucceeded by long legumenous ſeed-pods, which, whilſt young and tender are fine culinary eſculents, and the principal eatable part of the plant; alſo ſometimes the ripe ſeed or beans contained in them.

Claſs and Order, *Diadelphia Decandria*.

*Characters.*] CALIX, is monophyllous, and two-lipped, the upper one emarginated, and the under tridented. COROLLA, is papilionaceous, with a heart-ſhaped vexillum, reflexed on the ſides, oval wings as long as the vexillum, and a narrow keel, twiſted contrary to the ſun's motion. STAMINA, ten diadelphous filaments, and ſingle antheræ. PISTILLUM, an oblong, compreſſed, hairy germen; a filiforme, inflexed, ſpiral, downy ſtyle, and obtuſe hairy ſtigma. PERICARPIUM, a long, thick, coriaceous, pointed pod, containing kidney-ſhaped compreſſed ſeeds.

There is only one ſpecies of Kidney-bean proper for general culture, but it is very profuſe in varieties, and is the parent ſpecies of all thoſe noted kinds, known in our gardens, both dwarf-growers and climbers.

The ſpecies is:

PHASEOLUS *Vulgaris*.

*Common Kidney-bean.*] Conſiſting of the following principal varieties in two claſſes—dwarf-growers—and high-climbers, or runners.

*Dwarf Kinds.*

*Dwarf Kinds, their general deſcription is:*—The plants riſe each with an upright ſhort ſtem, branching out low into a buſhy head, from about ten or twelve inches to a foot and a half high, rarely ſending out runners; garniſhed with trifoliate leaves, and cluſters of white or purple flowers, in different varieties, ſucceeded by long, narrow, hanging ſeed-pods.

*Principal Varieties are:*] Small, early, white dwarf Kidney-bean——ſmall early yellow——early liver-coloured dwarf——early black or negro dwarf——larger white, or cream coloured dwarf——larger black and white ſpeckled dwarf, a good bearer—black-ſtreaked dwarf—ſpeckled amber dwarf—ſparrow-egg dwarf——Canterbury white dwarf, a great bearer—Batterſea white dwarf, alſo a very great bearer. All of which kinds are of upright dwarf buſhy growth, rarely exceeding fifteen or eighteen inches height; and ſeldom throw out runners, except the two latter ſorts, which ſometimes emit a few ſtragglers, but they ſeldom ramble far.

Obſerve that with reſpect to the above-mentioned colours of the varieties, it alludes to that of the beans or ſeed, which alſo often vary to ſeveral other intermediate colours and variegations.

Of the above varieties of dwarf Kidney-beans, the firſt three or four ſorts are at preſent in eſteem for their coming earlieſt into bearing; they being of ſmaller growth than the other ſorts, and ſooner form themſelves for bloſſom and bearing, ſo are proper to plant for the earlieſt crops, and for forcing in hot-beds, &c. As they, however, do not continue long in bearing, they are not ſo proper for the main crops, as the other larger dwarf ſorts; particularly the black and white ſpeckled, the Canterbury and Batterſea kinds, which are all excellent bearers; but the two latter moſt of all, and the pods are ſmaller, more numerous, and eſteemed the ſweeteſt eating of all the dwarf kinds whilſt young, though the pods of the large white dwarf, and the ſpeckled kind in particular, continue tolerably good, even when of a pretty large ſize; but in the Batterſea and Canterbury ſorts they are ſoon apt to become tough and ſtringy: theſe two ſorts, however, are in moſt eſteem for general culture by the market-gardeners in the neighbourhood of London, for the main crops, as being by them conſidered both

as the moſt profitable in bearing, and being a ſmaller pod, the moſt ſaleable in the markets.

As all theſe dwarf Kidney-beans are of upright growth, without emitting any very rambling runners, they do not require ſupport, like the climbing kinds; ſo may be cultivated in drills not more than two or three feet aſunder. See their *Propagation and Culture.*

*Climbing Kinds, or Runners.*

*Climbing Kinds, their general deſcription is:*—The plants riſe with a ſhort ſtalk; emitting ſeveral long, ſlender, twining runners, winding round any ſupport, many feet high; garniſhed with large trifoliate leaves; and at all the joints, as the runners advance, large cluſters of ſcarlet or white flowers in different varieties.

Of the climbing ſort are the following principal varieties.

*Large ſcarlet climber*,——Riſes with many twining runners upon ſupport, twelve or fifteen feet high, having numerous large cluſters of ſcarlet flowers; ſucceeded by large, thick, rough ſeed-pods, containing large, thick, purpleiſh beans.

*Variety of this.*] Large white climber, having large cluſters of white flowers, large, thick, rough ſeed-pods, and white ſeed.

Both theſe ſorts are alike in every reſpect of growth, and only differ in colour of their flowers and ſeed, as above; which is pretty permanent: they are both extraordinary great bearers; and the plants of the ſame crop continue in bearing from July or Auguſt until October; and the pods of both ſorts, even when large, boil exceedingly green, and are remarkably tender and well flavoured.

*Large Dutch Climber*,—Riſes with twining runners, upon ſupport, ten or twelve feet high; numerous cluſters of white flowers; ſucceeded by long, flat, ſmooth pods, containing large, oblong, flat, white ſeed.

This variety is alſo a very great bearer, but it does not continue ſo long in bearing as the two former climbers; and the pods, though very good eating, are rather inferior to thoſe of the ſcarlet kind, and its variety; it is nevertheleſs a very good family bean.

The following climbers are of more moderate growth.

Negro runners—Batterſea white runners—Canterbury runners—variable runners. All of which, though climbers, do not ramble far, and bear plentifully, but not continue ſo long as the above-mentioned climbers; the pods are ſmaller, but are excellent eating while young.

Thus far concludes all the principal varieties of the PHASEOLUS *Vulgaris*, or common Kidney-bean, that have merit for general culture.

In the different varieties, both of the dwarfs and climbers, the ſhape and ſize of the ſeed-pods, and ſeed vary a little, that is, the pods are generally long and narrow, i. e. from about three or four to ſix or ſeven inches long, and from about a quarter of an inch to an inch broad, and moſtly compreſſed, but in ſome are more flattened, and thinner than others, and ſome incline a little to a cylindric form, and of thicker ſubſtance; thoſe of ſome of the climbers are much larger than the dwarf; obſerving in general that as the young green ſeed-pod are, in this country, the principal edible part of the plant, thoſe of the thickeſt fleſhy texture that break criſp and tender, are generally preferable. And as to the ſeed, it is moſt commonly Kidney-ſhaped, though ſome incline a little to an oval form, and ſome roundiſh: in ſome varieties it is very ſmall, ſome middling, and ſome large; and according to the ſize of the ſeed, the plants of the reſpective varieties are generally ſmaller or larger in proportion. The ripe ſeed in ſome countries is alſo preſerved for eating in winter; but the moſt eſtimable part for uſe in England, is the young pods, as aforeſaid, whilſt they are green and tender, before the ſeed in them acquires any conſiderable ſize; they are thus boiled and eaten as ſauce to fleſh-meat. The quite young pods are alſo in great eſtimation for pickling, and make a very delicate pickle for uſe all the year: the young pods are alſo often ſalted down in barrels, or earthen veſſels, for winter uſe, in which they will keep exceedingly fine ſeveral months. The ripe ſeed alſo, as above hinted, of the white kinds, is ſometimes boiled for eating, particularly in France and ſome other parts on the continent, where they are conſtantly preſerved for winter uſe, as we do dried peas; which they ſtew and make very palatable with butter, gravy, and other ſauces.

All the varieties of this ſpecies, both dwarfs and climbers, are originally exotic annuals from the hot parts of the world; and in this country are rather of a delicate temperature,

ture, impatient of cold, and not able to bear the open air here only in ſummer; they being raiſed from ſeed in April, May, and June; and the firſt autumnal cold, in October or beginning of November, puts a period to their exiſtence.

*General Obſervations on their Culture.*

As Kidney-beans are univerſally of the annual tribe, a freſh ſupply muſt be raiſed every year from ſeed; and as the plants of the dwarf kinds rarely continue in bearing longer than three weeks, ſeveral different plantings or ſowings is neceſſary from April until July; but ſome of the climbing ſorts will continue bearing two or three months. Obſerving of all the ſorts, that, as being exotics of a tender nature, they will not ſucceed here in the full ground till April or May: the former of which is the earlieſt time for putting in the firſt crop, which will come into bloſſom in June, and by the latter end of that month will be ſucceeded by young pods fit to gather for uſe; and by different ſowings may continue a ſucceſſion of crops, bearing from June until October; but by aid of hot-beds may have the dwarf ſorts very early in the year; and with the accommodation of a hot-houſe, you may have them at almoſt any time in winter or ſpring, in very great perfection.

The dwarf ſorts are proper for the early and general ſummer crops; and for the ſupply of markets in particular, where large quantities are required, they are the only proper ſorts for general culture, both becauſe they require much leſs room to grow, and leſs trouble in their culture than the climbers, as not requiring to be ſticked; and the produce is generally more ſaleable, though not better for eating, only are to many perſons more agreeable to the eye. To have a conſtant ſupply of theſe ſorts in the natural ground from the earlieſt to the lateſt period, three or four different ſowings, at leaſt, are neceſſary from the beginning or middle of April until the latter end of July; and to have them as early as poſſible, ſome ſhould be ſowed in hot-beds in February and March; or in a hot-houſe they may be planted in the beginning or middle of winter, even to have beans at Chriſtmas, and continued, in ſucceſſion till thoſe in the common hot beds, or in the natural ground come into bearing.

The climbing kinds are, for the moſt part, wonderful great bearers, particularly the ſcarlet ſort, and its white variety, which in the ſame crop often continue bearing plentifully from July until killed by the froſt or cold in October; but all the climbers continue in bearing much longer than the dwarfs, for as their runners continue branching and ſhooting in length two or three months, they, according as they advance, continue ſending forth large cluſters of bloſſoms, ſucceeded by a proportional quantity of fruit: none of the climbers, however, are adapted for early crops; but ſucceed remarkably for the main crop, to ſupply the table from about the middle or latter end of July until October, eſpecially in private gardens, where only moderate quantities are required, and have convenience of ſticks to place for their runners to climb upon, for without ſuch aſſiſtance they would trail on the ground, and entangle with one another in a confuſed manner, and be liable to rot, without affording a quarter of a crop: they ſhould therefore all have ſticks for ſupport, and they will bear amazing great crops. But in the public kitchen-grounds, where conſiderable quantities of Kidney-beans are requiſite for the ſupply of market, the climbers are not ſo proper for any general crop, on account of the great trouble they would require in ſticking: beſides, as before obſerved, they are not ſo ſaleable as the dwarf ſorts, though they are equally good, if not ſuperior to ſome of thoſe kinds, for the table; the ſcarlet kind in particular claims preference. Obſerving, as all the climbing kind run up, by ſupport, very tall, and branch out into lateral runners all the way, they require large ſcope to grow, ſo ſhould generally be planted in drills four feet at leaſt aſunder.

The ſcarlet runner is alſo often employed as a flowery plant for the ſingularity of its flowers; ſometimes, likewiſe, its white variety, planting them in patches alternately in any of the compartments; alſo to run over arbours, or up the ſides of houſes, or to form ſhady walks, &c. See their *Culture*.

The general ſeaſon in which the main crops of all the ſorts of Kidney-beans arrive to perfection in the full ground, is July, Auguſt, and September; or by early and late planting may have them from June till October: obſerving that a conſtant ſucceſſion during theſe months is obtained by three or four different plantings, from the middle of April until July, as before hinted; which repetitions of plantings is abſolutely neceſſary for the dwarf kinds, which do not continue bearing long, ſome not

more

more than a fortnight, others three weeks or a month; but as to the climbers, as they continue ſhooting and flowering all ſummer, until prevented by the cold in October or November, two different plantings of theſe ſorts, one early in May, the other in June, will furniſh an abundant ſupply of young beans during the whole ſeaſon.

But, as before remarked, that in order to have a long ſucceſſion of Kidney-beans for the table, different modes of culture is practiſed, as the raiſing both dwarfs and climbers in the full ground for the main crops; and by artificial heat, in different ways, for the dwarfs in particular, to have very early crops.

The particular culture, however, both of the dwarfs and climbing ſorts, is exhibited below, each under its proper head.

*Propagation and General Culture of the Dwarf Kinds in the Full Ground.*

All the dwarf Kidney-beans, as well as climbers, are propagated by ſeed annually; and the ſeaſon for planting the natural crops in the full ground, is ſpring and ſummer, at ſeveral different times from April until July, in order to obtain a daily ſupply of young beans during the whole ſeaſon.

Obſerve to chuſe the proper ſorts for the different crops; that is, for the forward crops, you may uſe any of the firſt four early dwarf ſorts, but the early white and negro kinds, are rather the beſt, and longeſt bearers; and for the main crops any of the larger dwarf kinds may be proper, though I ſhould give preference to the ſpeckled dwarf and the Batterſea and Canterbury dwarf kinds, they being all plentiful bearers, and continue long in bearing, as obſerved in their deſcription.

It muſt be remarked, as already hinted, that as Kidney-beans are exotics of a tender nature, they ought not to be planted earlier than April, when the weather is become a little ſettled, for the ſeed is not only impatient of cold moiſture in the ground, and very ſubject to rot; but the young plants that happen to come up early, are often cut off, or greatly injured by the morning froſts, or cold cutting winds that frequently prevail in April and beginning of May. But towards the middle of April, if the weather is fine and dry, we may venture to plant pretty freely in a warm dry ſituation and light ſoil, for the early natural crops; and in the latter end of that month, or beginning of May, it is proper to begin to put in the firſt general crops in the open quarters, &c. and ſo continu, planting ſome every fortnight or three weeks until the middle or latter end of July: whereby you will have a regular ſupply of young Kidney-beans for the table or market from about the middle or latter end of June until October, as aforeſaid.

If, however, you are deſirous to try to have them as early as poſſible in the full ground, you may put in a few about the beginning of April, in dry weather, cloſe under a warm wall, to take their chance; and in a fortnight after put in a few more; if the firſt ſhould fail, theſe may ſucceed; and if both are attended with ſucceſs, one will ſucceed the other in bearing: though it is two to one againſt the ſucceſs of the firſt: but as only a few ſhould be planted ſo early, if they fail, it is only the loſs of a little labour and ſeed, the ground will do again; and if they ſucceed and produce only a few, but a week ſooner than common, they will be eſteemed a rarity either for family uſe, or market.

They all ſucceed in any common ſoil of a garden, remarking however, that for the forward crops it is abſolutely neceſſary to ſelect a dry light ſoil, rejecting heavy and wet grounds, for in ſuch a ſoil moſt of the early-planted ſeed would infallibly rot. Likewiſe for the early crops it is highly requiſite to chuſe a ſheltered warm ſituation full to the ſun, a warm ſouth border, is a very eligible expoſure; but for the main crops, any of the open quarters are proper.

The method of ſowing or planting all the ſorts is in ſhallow drills, from two feet to a yard aſunder, and are all to remain where ſowed. Obſerving the following hints.

For the early crop, chuſing a warm border, and taking advantage of a dry day, draw neat drills with an hoe from north to ſouth, two feet or thirty inches aſunder, and near an inch deep, and to have a greater chance, I would draw alſo a drill cloſe along under the wall, where practicable; in theſe drills drop the beans in a row along the bottom, only about an inch and a half aſunder, as many of this early ſowing may fail; covering them evenly with the earth, not more than an inch deep, for if covered deep at an early time, many are apt to rot, or at leaſt riſe ſtragglingly: as ſoon as they are covered in, lightly rake the ſurface ſmooth, and the work is finiſhed. They will come up in about ten or twelve days or a fortnight: managing them as hereafter directed, and

and the plants will come into bearing in ſix or eight weeks.

For the main crops intended to be planted in May or June, &c. you may employ almoſt any ſituation; either in borders, or in an open expoſure, though an open ſituation in any of the large quarters is the moſt eligible. Drawing drills two feet and a half aſunder, and about one inch deep; or, if deſigned to plant rows of ſavoys or cabbage-plants between, as is often practiſed when neceſſary to huſband the ground to the beſt advantage, the drills ſhould be a yard aſunder at leaſt; drop the beans ſingly along the bottom of each drill, about three inches aſunder, covering them in evenly with the earth about an inch deep, and finiſh with a light raking to ſmooth the ſurface. They will come up, at this ſeaſon, in eight or ten days, and ſometimes ſooner in fine weather; and the plants will come into bearing plentifully in July and Auguſt.

In the above manner continue planting ſome every fortnight or three weeks until July, as we before adviſed; and you will have a plentiful daily ſupply of young beans, from June until Michaelmas or longer.

In planting the latter crops in June and July, when the weather proves very dry and hot, and the ground alſo very dry, it is proper either to ſoak the beans a few hours in ſoft water previous to planting, or inſtead of this let the drills for the reception of the beans be well watered, and immediately plant them as above, and cover them in the proper depth. Either of theſe methods is very adviſable in dry weather in the heat of ſummer; it being neceſſary at ſuch times to promote the free germination of the ſeed, to bring them up ſoon and regularly, which would otherwiſe riſe in a ſtraggling manner.

When the plants of all the above crops are come up, their general culture is as follows.

They are in general to remain where ſowed or planted to yield their produce; obſerving to keep them clean from weeds by occaſional hoeing in dry weather; and when the plants are advanced about three or four inches high, hoe up a little earth to their ſhanks on each ſide, which will forward their growth, and promote their ſtrength: continuing the care of deſtroying weeds as often as their growth ſhall render it neceſſary; which is all the culture required for the dwarf Kidney-beans in the full ground till they arrive at a bearing ſtate, and their produce is fit to gather.

With reſpect to gathering the produce of theſe ſorts of Kidney-beans, it ſhould always be performed when the pods are quite young, or at leaſt before they become large, and the beans in them attain any conſiderable ſize, as they would then be tough, ſtringy, and rank-taſted; and in order to continue the plants in bearing as long as poſſible, the gathering ſhould be regularly repeated about three times a week; for by gathering the pods often and clean, as they become fit, the plants will bloſſom more abundantly, and continue fruiting more plentifully and longer accordingly.

Great quantities of theſe dwarf kinds are cultivated in the gardens and fields in the neighbourhood of London, for ſupplying the markets: where they are brought in large, flat, round baſkets, called junks, from about half a buſhel to a buſhel ſize; which with the aſſiſtance of large cabbage leaves placed all around, are filled with the beans heaped up conſiderably, ſo as to have as much again at top as within; and are thus bound tight with cords, carried over and acroſs, and in that manner carried ſecurely to market in carts or waggons, &c. and there ſold by the baſket, at various prices, according to the ſize of the baſket, and youngneſs and quality of the beans; but at firſt coming in they often fetch from five to eight or ten ſhillings per baſket, and fall by degrees to two ſhillings or half a crown, or a little leſs or more according to the ſize of the baſket, &c.

### *Propagation and Culture of the Climbing Kinds.*

The propagation and culture of the climbing Kidney-beans, commonly called runners, is, they are all raiſed from ſeed annually in ſpring and beginning of ſummer, as obſerved of the dwarfs; and their general culture is nearly the ſame as for thoſe ſorts in the full ground; only they require more room to grow, and muſt have tall ſticks or poles placed for their runners to twine or climb upon, as already noticed. Obſerving none of theſe climbing kinds are proper for early crops, neither in the open ground or hot-beds, ſo ſhould be cultivated principally for ſummer and autumn crops, to come into bearing from July until Michaelmas.

Of theſe climbing kinds I ſhould recommend the ſcarlet runner and its white variety, for the general crops, they being both extraordinary great bearers; continuing in perfection two or three months; and their pods, when even pretty large, remain green, fleſhy, tender, and well flavoured. Some of the Dutch runners, and a few of the other climbers alſo merit culture.

The moſt eligible ſeaſon to begin planting the main crops of all theſe ſorts is the firſt or ſecond week in May, if the weather is fine; for being of a delicate nature like the dwarfs, if planted earlier, both the ſeed and plants are ſubject to danger from the ſame cauſes; however, in a warm ſituation and dry ſoil, a few may be planted in the middle or latter end of April, to take their chance; but remarking, that for the general crops, the moſt ſucceſsful ſeaſon for planting is from May, as aforeſaid, until the beginning of July; but if you plant principally the ſcarlet kind and variety, one planting in May or beginning of June, will come into bearing in July; and if you keep gathering the pods clean, according as they are fit for uſe, the plants will continue ſhooting, bloſſoming, and bearing abundantly until the end of September, or often until the end of October, or till deſtroyed by the cold; but two plantings of any of the ſorts of runners, one in May and the other in June, or early in July, will furniſh a very abundant ſupply the whole ſeaſon of Kidney-beans.

All theſe climbing kinds will proſper almoſt any where in a garden, both in cloſe and open ſituations: chuſing principally a lightiſh ſoil, eſpecially for the forward crops, and the richer the ground the better.

Obſerve, that as all the running kinds require ſupport of ſome ſort to climb upon, they ſhould be planted either in wide rows, for the convenience of placing tall ſticks or poles along each row for the runners of the plants to wind themſelves for ſupport; or planted againſt ſome ſort of fence or treillage-work for the ſame purpoſe of training up and ſupporting the runners. When, however, it is deſigned to train them upon ſticks or poles, let drills be drawn four feet, or four and a half aſunder, eſpecially for the larger kinds, and an inch deep; in which drop the beans, three or four inches apart: cover them in evenly with earth, and rake the ſurface ſmooth. The beans will ſprout in a few days, and come up in leſs than a fortnight.

When the plants are three or four inches high, draw a little earth with an hoe up to their ſtems, to ſtrengthen them and encourage them to ſend forth ſtrong runners. At this time alſo cut down all weeds between the rows.

As ſoon as they begin to puſh their runners, begin to place ſome tall ſticks or poles for them to aſcend upon: as you place the ſticks conduct the runners towards them, in a direction according to their natural mode of climbing, which is generally to the right or contrary to the ſun's motion: they will thus naturally encircle the ſtick or poles, and aſcend to their tops, even if ten or fifteen feet high, producing bloſſoms and fruit from bottom to top.

When intended to plant theſe ſorts againſt fences for ſupport, plant them in a row cloſe along to the fence, and their runners, if againſt a wall or paling, may either be nailed up as they advance in length, or there may be ſome ſtrong packthread ſtring drawn from top to bottom at ſix inches diſtance; the plants will readily twine round them, and ſupport themſelves.

In gathering the produce of all theſe kinds, obſerve the ſame as of the dwarfs, to gather the pods whilſt young and tender; and to continue the plants long in full bearing, always gather the pods clean as they become of proper ſize, and they will continue fruiting abundantly.

If you intend cultivating any of theſe climbing Kidney-beans as flowering-plants, the ſcarlet kind and its variety, as before ſuggeſted, are the proper ſorts. Sow them any time from about the middle or latter end of April until July, in any of the compartments of the pleaſure-garden, in patches, alternately ſcarlet and white ſort, two or three beans in each patch, about an inch deep; and when the plants are up and begin to puſh runners, place tall poles or branchy ſticks for them to climb upon: they will effect a very fine variety all ſummer until October.

They are alſo often employed to run over arbours, and to twine round the ſtems of trees; alſo to run up the ſides of houſes, or againſt walls, either upon poles, or upon packthread-ſtrings, ſuſpended from above, about which they will twine themſelves many feet high, bearing abundance of flowers and fruit: they are likewiſe ſometimes trained to form ſhady private walks, by means of high poles arranged along each ſide, or by ſupport of a

ſort

ſort of treillage-work, ranging ſome tall ſtakes five feet aſunder, railing them along the top with poles, or pan-tile laths; from which ſuſpending ſtrings to the ground, ſix or eight inches aſunder, faſtening them down with pegs: upon theſe ſtrings the plants will climb and form a cloſe hedge. Some perſons are alſo curious enough to arch over the tops of ſuch walks with any long, ſlight, pliable rods, poles, or hoops, ſo train the runners of the plants over to form a ſort of a vaulted roof all the way along. Thus this fine climber may be trained in various ways according to fancy, both for uſe and pleaſure, as may be obſerved in the numerous ſmall pleaſure-gardens in the environs of London; and thoſe not accommodated with gardens, plant them in pots or boxes, to place in windows or balconies, &c. and train the plants upon ſtrings, as juſt above obſerved.

*Early Crops of the Dwarf Kinds by Artificial Heat.*

To have Kidney-beans as early as poſſible, recourſe is had to raiſing the dwarf kinds by aid of artificial heat, by two or three different methods, ſuch as—By raiſing the plants in a hot-bed, an inch or two high, and then plant them out into a warm border—By raiſing and continuing the plants in a hot-bed to bear their crops—By aid of a hot-houſe.

1. By raiſing in a hot-bed for tranſplantation into warm borders.—By this method we may forward Kidney-beans a fortnight earlier than thoſe raiſed entirely in the full-ground: for this purpoſe, towards the latter end of March, prepare a moderate hot-bed, a foot and half depth of dung, covered either with a frame or hand-glaſſes, or arched over with hoops or rods, to be covered with mats; earthing the bed with fine, light, rich mould, ſix inches deep; then having ſome ſeed of the early dwarf ſorts, ſow them pretty cloſe for tranſplantation, either all over the ſurface, an inch or two apart, covering them with earth about half an inch deep; or in ſmall drills two or three inches aſunder, and cover them the above depth; though it will be rather moſt eligible to plant them in the drills by pairs, at three inches diſtance from pair to pair, and the plants can be more readily tranſplanted two and two with balls of earth to their roots; or where only a few is wanted, they may be ſowed in large pots, at about an inch diſtance and half a one deep, and the pots plunged into any hot-bed; and when the plants come up, the pots may be removed by degrees into the full air, to harden the plants for tranſplantation. But it is a good method to plant a quantity of beans in ſmall pots (thirty-twos), three in each pot, plunging the pots in a hot-bed, and when the plants are fit for tranſplantation, they can be readily turned out of the pots with the whole ball of earth about their roots ſo as not to feel their removal.

However, in raiſing the plants in either of theſe methods for tranſplantation in the full ground, your attention is particularly neceſſary to inure them gradually to the full air, by taking off the covers of glaſſes or mats in all mild weather, and only cover them in cold nights; but as they advance in growth, and the weather becomes warmer, they muſt be expoſed by degrees to the full air, day and night, to harden them properly previouſly to their final tranſplantation. Obſerving alſo to allow them frequent moderate refreſhments of water, and let them enjoy the benefit of warm ſhowers.

When they have ſhot out their proper leaves an inch or two broad; and all danger of froſty mornings and other bad weather is apparently over, proceed to plant them out into a warm border, under a wall or other fence. Obſerving particular care to take them up with their roots as entire as poſſible, and with as much earth as will hang about them, thoſe eſpecially that are raiſed by pairs, may be readily taken up, each pair with a ball of earth; and thoſe raiſed in ſmall pots by threes may alſo be eaſily turned out with the whole ball of earth entire; and as to the mode of planting them, thoſe which were raiſed cloſe together, and could not readily be taken up with balls, may be planted by dibble, in rows two feet aſunder, forming ſhallow drills for their reception, in which ſet the plants three or four inches apart; but thoſe with good balls about their roots, ſhould be holed in with a trowel; and if ſome of thoſe are alſo diſpoſed in patches, two or three plants in each, ſo as to be covered occaſionally in cold nights with hand-glaſſes, it will be found very beneficial in forwarding their growth. As ſoon as they are planted, in either method, give a moderate watering to ſettle the earth cloſe about the roots, and let it be repeated in dry weather as there may be occaſion, till the plants have taken freſh-root in their new quarters.

After this keep them clean from weeds, and when a little advanced in growth, draw ſome earth lightly up about their ſhanks; and as the warm ſeaſon advances, if it proves hot and dry, refreſhments of water will forward and ſtrengthen the growth of the plants.

Thus this crop of Kiney-beans will ſometimes arrive to a bearing-ſtate a fortnight ſooner than thoſe raiſed entirely in the natural ground.

2. By Hot-beds entirely.—To have Kidney-beans as early as poſſible, is effected by raiſing the ſmall early dwarfs in hot beds, and continuing them there to attain perfection, whereby they may be forwarded to a bearing ſtate in April and May: the method is this, proceed about the beginning or towards the middle of February, to make a dung hot-bed, for one, two, or more three-light frames, about two feet and a half high in dung: and when the great heat and ſteam are a little abated, earth the bed with light, rich, dry mould, ſix or eight inches thick, for the reception of the ſeed (ſee HOT-BEDS); then having ſome ſeed of the ſmall early dwarf kinds, draw drills from the back to the front of the bed, near an inch deep, and about fifteen or eighteen inches aſunder; here place the beans two or three inches apart, and cover them evenly with the earth the above depth; then put on the lights: but tilt them behind an inch or two high daily, ſo give vent to the ſteam; and when the plants appear, continue every day to admit air to them at all opportunities, in proportion to the temperature of the weather, and heat of the bed, to prevent their drawing weak, and to promote their ſtrength as they riſe in height; beſtow alſo at this time moderate refreſhments of water in ſunny days; and when they are two or three inches high, apply a little earth to their ſhanks; likewiſe ſupport a moderate heat in the bed during the cold weather, by occaſional linings of hot dung: obſerving according as the plants advance in growth, and the warm ſeaſon encreaſes, augment gradually the portion of freſh air daily to harden them by degree, ſo as almoſt to be fully expoſed occaſionally in very warm days, eſpecially when beginning to bloſſom, but keep them cloſe on nights: continue alſo the care of frequent light waterings, which muſt be increaſed in quantity as the plants advance in ſize, particularly when they are in bloſſom, and in a fruiting-ſtate: in their advanced growth, if they preſs much againſt the glaſſes of the frame, it is proper to raiſe it at bottom two or three inches, to give room at top for their free growth; which being neceſſary to promote a plentiful bloom, for furniſhing a proper crop of Beans equal to the expence and trouble requiſite in the culture of ſuch early crops.

They will thus arrive to full growth, and produce early young Beans for the table in April and May.

But to obtain a conſtant ſucceſſion of early Kidney-beans till the natural-ground crops come in, we ſhould proceed with another crop in hot-beds, as above, in three weeks after the firſt hot-bed is made.

In default of frames for the above purpoſes, you may in March effect it with occaſional coverings of mats; that is, make a hot-bed about two feet high of dung, earthing it directly ſix or ſeven inches thick, and ſow the beans as before directed; then arch the bed over with hoops, &c. and cover every night, and all bad weather, with mats: but admit the free air every mild day, gradually hardening the plants as they acquire ſtrength, and give occaſional waterings: thus they will furniſh beans early in May.

3. By Aid of a Hot-houſe.—If you are accommodated with a hot-houſe or ſtove, early Kidney-beans may be obtained with very little trouble at almoſt any time in winter or ſpring: raiſing them in pots, or long narrow trough-like boxes, about a yard long and eight or ten inches broad at top; placing either any where in the hot-houſe, the plants will ſucceed, obſerving as below.

The proper kinds for this purpoſe is the early white or liver-coloured dwarfs: the ſpeckled dwarf alſo ſucceeds very well, and continues long in bearing.

Therefore any time in winter or early in ſpring, you may fill ſome large pots (ſixteens or twenty-fours) or boxes with light rich earth, and place them upon the top of the wall which ſurrounds the bark-bed, or upon ſhelves or in any part of this department where convenient; and in each pot plant four beans, near an inch deep; or, if boxes, plant the beans along the middle, in a ſort of double row, triangular-ways, about four inches aſunder, and the above depth: they will ſoon germinate, and in a few days appear above ground: when they, however, begin to ſprout, it is proper to moiſten the mould with a little water, which will facilitate

cilitate the eruption of the plants out of the earth.

Their culture here is very eaſy: when they are come up, give frequent waterings, which will be requiſite three times a week, at leaſt, in this department, as the earth will dry very faſt; but always keep it moderately moiſt, and the plants will bloſſom freely, and produce a plentiful crop of beans, often in as great perfection as in the full-ground crops.

They ſhould be gathered often, which is the way to continue the plants long in bearing.

A regular ſucceſſion of young Kidney-beans may be obtained in this repoſitory for ſeveral months; by repeated ſowings at about three weeks interval, ſo as to have young plants advancing in pots or boxes in two or three different degrees of growth ſucceeding one another.

But as ſometimes we are ſtraitened for ſtove-room, it may be proper to plant the beans for ſucceſſion crops in ſmall pots (forty-eights) three beans in each, and as theſe will take up but little room, they may be ſtowed any where cloſe together, or between the other larger pots; the plants will come up and be advancing in growth, ſo as when thoſe of the preceding crops are going off, theſe may be readily turned out of the ſmall pots with the whole ball of earth about their roots, and replanted into large pots, &c. to remain for fruiting.

By this practice you will gain a month's growth in the plants, and you may thereby have a conſtant ſucceſſion of beans for the table.

*Saving Seeds of all the Sorts.*

With reſpect to ſaving ſeed of Kidney-beans, all the ſorts ripen plenty in Auguſt and September.

To have perfectly good ſeed, it is proper to ſow a ſufficient quantity in rows on purpoſe, ſuffering the whole crop of the plants to remain without gathering any for uſe: you will thus have the ſeed ripen betimes, and in the higheſt perfection, which is eſſentially neceſſary for thoſe who deſign the ſeed for public ſupply.

In private gardens, however, and many others, they often after having gathered the flower as it were of the principal crops, leave the latter produce of them to grow for ſeed; which, although it may be tolerable good, it is not always ſo large, plump, and fine, as in the former method.

When the ſeed is quite ripe, which is eaſily known by examining a few of the pods, pull up the plants, and ſpread them looſely along in rows, turning them daily that the beans may dry and harden well, which when effected, either threſh them out directly, or lay them up in ſome dry loft or other room till convenient; and when threſhed out, and cleared from the rubbiſh, ſpread them upon ſome clean airy floor, or ſome ſuch place in the dry to harden perfectly, then put them up in bags for next year's uſe.

It is of much importance to have change of ſeed once in two or three years; that is, if you always ſave your own, it is adviſeable either to change a quantity of ſeed with ſome friend at a diſtance, or purchaſe a freſh ſupply once in the above mentioned time; for by ſaving ſeed always in the ſame ground, it will degenerate, the plants will become every year weaker, and deficient in bearing. But by change of ſeed from ſome diſtant place, as above, you will have the different ſorts always in their ultimate ſtate of perfection.

PHILADELPHUS, *Syringa*, or Mock-Orange.

Two hardy, deciduous, flowering ſhrubs compoſe this genus, furniſhing ſome varieties; all noted floriferous plants for the ſhrubbery, riſing ſeveral feet high, branching out into buſhy heads, decorated with large oval leaves, and numerous cluſters of tetrapetalous white flowers.

Claſs and order, *Icoſandria Monogynia.*

*Characters.*] CALIX, is monophyllous, acutely four-parted, and perſiſtent. COROLLA, four large, roundiſh, plane, ſpreading petals. STAMINA, twenty or more awl ſhaped filaments, having erect four-furrowed antheræ. PISTILLUM, a germen under the corolla, ſlender four-parted ſtyle, crowned by ſimple ſtigmas. PERICARPIUM, an oval-acute-pointed, quadrivalved, quadrilocular capſule, containing numerous ſmall oblong ſeeds.

There are but two ſpecies, both hardy deciduous ſhrubs, originally of foreign growth; but one of which has been long a reſident of our gardens, is a very noted ornamental flowering ſhrub, compriſing ſome varieties.

The ſpecies are;

1 PHILADELPHUS *Coronarius.*

*Coronarius-flowered Syringa, or Common Mock-Orange.*] Riſes with many ſhrubby, ſlender,

ſlender, brown ſtems, of a brittle and pithy nature, branching five or ſix feet high, the branches by oppoſite pairs, alternately of contrary directions, jointed, and covered with a brown ſmooth bark; large oval-ſpear-ſhaped, rough, ſlightly-indented, oppoſite leaves; and at the axillas and termination of the branches many large looſe bunches of white, very fragrant flowers; appearing in May and June.

The flowers, both in figure and ſcent, reſemble thoſe of the orange-tree: hence the appellation Mock-orange.

*Varieties.*] Dwarf coronarius Syringa—double-flowered dwarf. Both theſe varieties grow only about two or three feet high, garniſhed with ſmall leaves, and the flowers generally riſe ſingly, but the plants rarely flower.

[2]PHILADELPHUS *Inodorus.*

*Inodorous, or Scentleſs Carolina Syringa.*] Riſes with a ſhrubby ſtem, branching twelve or fourteen feet high; oval-ſpear-ſhaped, entire leaves; and the branches terminated by large, white, ſcentleſs flowers.

Both theſe ſpecies of *Philadelphus* are elegant furniture for the ſhrubbery compartments: the firſt ſort, however, and varieties, are the principal kinds at preſent in our gardens, the ſecond ſort being more rare in this country; but both the ſpecies are equally hardy, and will ſucceed in almoſt any ſoil and ſituation, and produce a profuſion of flowers annually, particularly the Coronarius Syringa, which is in a manner covered with bloom, and exhibit a very ornamental appearance for a month or ſix-weeks, and emits an odoriferous ſcent widely around.

*Their Propagation, &c.*

The propagation of all the ſorts is remarkably eaſy——by ſuckers——layers——and cuttings.

By Suckers.—All the ſorts ſend out numerous ſuckers from the root, which may be ſeparated from the parent plant, any time in open weather from October till March, and planted in nurſery-rows, to remain one, two or more years to obtain ſtrength, and then may be tranſplanted into the ſhrubbery.

By Layers.—Any time from October till March lay a quantity of the young branches, they will be rooted and fit for tranſplantation in autumn following, managing them as directed above for the ſuckers.

By Cuttings.—In October or November plant a quantity of the young ſhoots in any ſhady border, many of them will form proper plants in one year.

PHILLYREA, (*Phillyrea*) Mock-privet.

This genus conſiſts of beautiful ever-green ſhrubs for adorning the ſhrubbery-compartments; riſing from about ſix or eight to twelve or fourteen feet high, branching numerouſly and diffuſely into buſhy heads; cloſely garniſhed with oval moderate-ſized leaves, and cluſters of ſmall monopetalous funnel-ſhaped greeniſh-white flowers.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is monophyllous, four-parted at top, and permanent. COROLLA, is monopetalous and funnel-ſhaped, with a ſhort tube below, and the limb or upper part divided into five revolute ſegments. STAMINA, two ſhort filaments with ſimple erect antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and a thickiſh ſtigma. PERICARPIUM, a globoſe unilocular berry, having one large globular ſeed.

There are but three ſpecies, all of which are hardy ever-greens of the ſhrub kind; but the *Phillyrea* and a ſpecies of *Rhamnus*, called *Alaternus*, are often miſtaken for each other, on account of the great ſimilarity in their general port or habit; there is, however, this very obvious diſtinction, the leaves of the *Phillyrea* always grow oppoſite by pairs; thoſe of the *Alaternus* ſtand ſingly in alternate arrangement; beſides there is a claſſic difference in their fructification: the former having only two filaments, and the latter five; ſo that one is of the claſs *Diandria*, the other *Pentandria*. See RHAMNUS *Alaternus.*

The ſpecies of *Phillyrea* are:

[1]PHILLYREA *Media.*

*Middle Phillyrea, or oval-leaved Mock-Privet.*] Hath a ſhrubby upright ſtem, branching diffuſely ten or twelve feet high; oval-lanceolate, almoſt entire, ſmooth, oppoſite leaves; and at the axillas of the branches, cluſters of ſmall greeniſh-white flowers.

*Varieties.*] Privet-leaved—olive-leaved.

[2]PHILLYREA *Latifolia.*

*Broad leaved Phillyrea.*] Hath a ſtrong, ſhrubby, upright ſtem, branching erectly about twelve or fourteen feet high; oval-cordated, ſharply-ſerrated, oppoſite leaves; and at the axillas cluſters of ſmall greeniſh flowers.

*Varieties.*] Prickly ilex-leaved—ſlightly-ſerrated leaved.

[3]PHIL-

3PHILLYREA *Anguſtifolia.*

*Narrow-leaved Phillyrea.*] Hath a ſhrubby ſtem, branching moderately about eight or ten feet high; long, narrow, ſpear-ſhaped, very entire, oppoſite leaves; and at the axillas of the branches cluſters of ſmall whitiſh flowers.

*Varieties.*] Roſemary-leaved——lavender-leaved—ſtriped-leaved.

All theſe three ſpecies and reſpective varieties, flower annually in March; the flowers are univerſally monopetalous hermaphrodites, ſmall and greeniſh, ſo make no ſhow; and in all the ſorts are ſucceeded by ſmall round berries, ripening in autumn to a black colour, each containing one ſeed. See the *Characters.*

They are all delightful ever-green ſhrubs, of a free eaſy growth, with long ſlender branches, covered with a browniſh or greyiſh bark, and cloſely garniſhed with their beautiful foliage the year round; which are generally of a thick, ſtiff conſiſtence, with a ſmooth gloſſy ſurface, appearing very ornamental at all ſeaſons; ſo that the ſhrubs are finely adapted to all the ſhrubbery compartments in aſſemblage with other ever-greens: they alſo appear well when detached here and there as ſingle objects; and they formerly were often planted for internal hedges, to divide the quarters of wilderneſs-works, &c. in which they have a beautiful effect: they are alſo well calculated for planting to hide any naked or old diſagreeable wall, &c. eſpecially the boundary walls of fore courts or other principal parts; in which they may be intermixed with a *Alaternus* for a variety, training their branches cloſe to the wall, and they will ſoon ſpread and cover it effectually; when they may either be ſuffered to branch according to nature, or may be trimmed cloſe every year in ſpring and ſummer.

No good ſhrubbery, however, ſhould be without a collection of theſe fine ever-greens, diſpoſed in the moſt conſpicuous points of view, there ſuffered to branch in their own rural manner, only juſt regulating with your knife any very ſtraggling branches.

### *Their Propagation.*

The propagation of all the three ſpecies of this genus is by ſeed and by layers.

By Seed.—This ſhould generally be ſowed in autumn, ſoon after it is ripe, and probably it will come up the ſpring following; tho', for the moſt part the ſeed of all theſe plants remain until the ſecond ſpring before they germinate; chuſe, however, a light ſandy ſoil for the reception of the ſeed, which ſow evenly, either all over the ſurface, covering it with earth an inch deep, or in ſhallow flat drills about the ſame depth: keep the earth very clean from weeds, both before and after the appearance of the ſeedlings: giving alſo frequent waterings in dry weather. Obſerving, it is proper to let them have two years growth in the ſeed-bed: remark, however, at the approach of winter, it will be proper to arch the bed over with hoops, or rods, in order to ſhelter the ſeedlings with mats in time of ſevere froſt for they are tender whilſt young; but after the ſecond ſummer's growth they become tolerably hardy, and may then be planted out either in autumn following, or in the enſuing ſpring, February or March, when the weather is ſettled, planting them in nurſery-rows to remain two or three years, or more, to acquire due ſize for the ſhrubbery.

By Layers.—Autumn is the beſt ſeaſon, though it may alſo be performed in winter and ſpring; chuſing the young ſhoots, which lay either by ſlit-laying, or by twiſting at a joint, and they will be rooted by autumn following; when they may be ſeparated from the parent plant, and planted in nurſery-lines, to remain till fit for the ſhrubbery-plantations.

PHLOMIS, Jeruſalem Sage, and *Leonurus.*

This genus furniſhes ſome eminent ſhrubby and under-ſhrubby ever-greens, for the pleaſure-ground and green-houſe collection; all of which are of upright growth, garniſhed moſtly with ſimple entire leaves, in ſome ſorts aſſuming a beautiful hoary whiteneſs, and monopetalous, ringent, very ornamental flowers.

Claſs and Order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, is monophyllous, tubular, oblong, five-angled, and permanent. COROLLA, is monopetalous, with an oblong tube, ringent above, having the upper lip oval, arched, and reflexed; and the under three-parted, the middle part large and obtuſe. STAMINA, two long and two ſhort filaments, and oblong antheræ. PISTILLUM, a quadripartite germen, a ſtyle the length of

of the ſtamina, and a bifid acute ſtigma. PERICARPIUM, none, four naked ſeeds lodged in the calix.

There are many ſpecies, but not more than four common to the Engliſh gardens, all of which are of a ſhrubby nature, two of them hardy for the ſhrubbery, and two for the green-houſe.

*Hardy Kinds for the Shrubbery.*

Theſe ſorts are ever-greens, and are remarkable in having their branches and leaves of a hoary white colour, in which they exhibit a ſingular variety.

[1]PHLOMIS *Fruticoſa.*

*Shrubby Yellow Phlomis, commonly called Jeruſalem Sage.*] Hath a ſhrubby thick ſtem, branching irregularly four or five feet high, the ſtem and older branches having a looſe ragged bark, and the young branches four-cornered and woolly; roundiſh-oblong, crenated, hoary-whitiſh leaves, by oppoſite pairs on woolly foot-ſtalks; and from the upper parts of the young ſhoots, large whorled bunches of yellow flowers. In June, July, and Auguſt.

*Varieties.*] Common broad-leaved—narrow-leaved—dwarf Cretan ſage-ſhrub.

[2]PHLOMIS *Purpurea.*

*Purple Portugal Phlomis.*] Hath an under-ſhrubby ſtem, branching four feet high, having ſlender, angular, white branches, oblong, cordated, hoary leaves; and from the joints of the branches whorls of deep-purple flowers. In June and July.

Both theſe ſpecies proſper in the open ground, and as they retain their hoary-white leaves all the year, are highly ornamental in ſhrubberies; they, however, were formerly kept in pots, and treated as green-houſe plants; but this is unneceſſary unleſs for variety, for they will ſucceed in any of the ſhrubbery compartments the year round.

*Green-houſe Kinds.*

Theſe ſorts were formerly of the genus *Leonurus*; but modern botaniſts have ranged them as ſpecies of *Phlomis*.

[3]PHLOMIS *Leonurus.*

*Leonurus, or Lion's-Tail, commonly called African Scarlet Leonurus.*] Riſes with a ſhrubby branching ſtem ſeven or eight feet high, having four-cornered branches; ſpear-ſhaped, ſerrated, oppoſite leaves; and towards the ends of the branches, whorls of cloſe-ſitting ſcarlet flowers, having ten-angled cups indented into ten parts; flowering in October and November.

*Variety.*] With variegated leaves.

[4]PHLOMIS *Nepetæfolia.*

*Nepeta-leaved Cape Leonurus.*] Riſes with a ſhrubby branching ſtem, a yard high, having four-cornered branches; oval leaves, oppoſite by pairs; and whorls of ſcarlet flowers, having ten-angled cups, indented into ſeven equal parts; flowering in October and November.

All theſe four ſpecies of *Phlomis* have great merit as ornamental plants, both as ever-greens, and for the beauty of their flowers, as they all flower very ornamentally every year in our gardens; thoſe of the *Leonurus* kinds in particular, make a fine appearance; but the flowers of all the ſorts are numerous, and being collected into large verticilli towards the ends of the branches, are very conſpicuous; they are univerſally monopetalous, ringent, and hermaphrodite. See the *Characters.*

The two hardy kinds are choice ornaments for the ſhrubbery, their hoary branches and leaves will exhibit a delightful contraſted variety in aſſemblage with other different ever-greens; ſuffering them to branch in their own way.

The two green-houſe kinds highly merit culture for the beauty of their flowers in particular; they muſt be potted in rich earth, and managed as other ſhrubby exotics of the green-houſe collection.

*Their Propagation.*

The propagation of all the ſorts is by layers and cuttings.

By Layers.—The two hardy ſorts in particular grow freely by layers, chuſing the young branches, and lay them in the common way any time in the year, they will readily ſtrike root, and commence proper plants by autumn after, when they ſhould be tranſplanted.

By Cuttings.—Plant a quantity of young ſhoots in ſpring or ſummer, in a ſhady border; give plenty of water in dry weather; many of them will root and make good plants, by the next autumn.

Remark, however, the cuttings of the green-houſe kinds, ſhould, if in ſpring, be planted in pots, in order to be continued in ſhelter until May; or if the pots are plunged in a hot-bed it will greatly forward their root-

ing; though young ſhoots planted in June or July in a bed or border of rich earth, many of them will take root, but may be much forwarded if covered down cloſe with hand-glaſſes, removing the glaſſes when the cuttings begin to ſhoot.

PHLOX, *Lychnidea*, or Baſtard-Lychnis.

The plants of this genus are herbaceous, fibrous-rooted, flowery perennials for adorning the pleaſure-garden; riſing with upright annual ſtalks, from one to two or three feet high, garniſhed with ſpear-ſhaped and oval leaves, and terminated by cluſters of monopetalous, hypocrateriforme, purple or reddiſh flowers.

Claſs and Order, *Pentandria Monogynia*.

*Characters.*] CALIX, is monophyllous, quinque-dented, and permanent. COROLLA, is monopetalous, and hypocrateriforme, with a cylindric crooked tube, and a plane limb, divided into five obtuſe ſegments. STAMINA, five filaments within the tube, and antheræ placed in the chaps of the corolla. PISTILLUM, a conical ſlender ſtyle, and trifid acute ſtigma. PERICARPIUM, an oval, trigonal, trivalvular, trilocular capſule, having one oval ſeed in each cell.

There are about nine or ten ſpecies, the moſt material of which for our purpoſe are the following ſix ſorts.

[1]PHLOX *Glaberrima*.

*Smooth Virginia Lychnidea.*] Hath creeping perennial roots; upright, herbaceous, ſmooth ſtems, near two feet high; narrow, ſpear-ſhaped, ſmooth, oppoſite leaves; and the ſtalks terminated by corymboſe cluſters of reddiſh flowers. Appearing in June or July.

[2]PHLOX *Carolina*.

*Carolina Shining-leaved Lychnidea.*] Hath a ſtrong, creeping, perennial root; upright rough ſtems, two feet high; ſpear-ſhaped, ſtiff, ſhining, ſeſſile leaves, by pairs oppoſite; and the ſtalks terminated by a flat corymbus of deep purple flowers. Appearing in July.

[3]PHLOX *Paniculata*.

*Paniculated American Phlox, or Lychnidea.*] Hath perennial roots; upright, herbaceous, branchy ſtems, two or three feet high; ſpear-ſhaped, rough-bordered, cloſe-ſitting, oppoſite leaves; and the ſtalks terminated by a paniculated-corymbus of pale-purple flowers. Appearing in July and Auguſt.

[4]PHLOX *Divaricata*.

*Divaricated Blue Virginia Phlox, or Lychnidea.*] Hath perennial roots; herbaceous, ſlender, weak, divided ſtems, having the branches divaricated or ſpreading from each other; broad, ſpear-ſhaped, ſeſſile leaves, the upper ones placed alternately; and pedunculi by pairs, ſupporting looſe bunches of light-blue flowers. Appearing in May and June.

[5]PHLOX *Maculata*.

*Maculated or Spotted ſtalked Virginia Phlox.*] Hath a perennial root; upright, taper, rough, purpleiſh, white, and red-ſpotted ſtems, a yard high, branching by oppoſite pairs; ſpear-ſhaped, ſmooth, amplexicaule, oppoſite leaves; and the branches terminated by a corymbus of bright-purple flowers. Appearing in July and Auguſt.

[6]PHLOX *Piloſa*.

*Hairy Virginia Phlox.*] Hath a perennial root; upright, ſingle, ſlender ſtalks, about a foot high; ſpear-ſhaped, acute, hairy, ſeſſile leaves; and the ſtalks terminated by a corymbus of light-purple flowers. Appearing in June and July.

All theſe ſix ſpecies of *Phlox* are hardy perennials, originally from North America; durable in root, but renew their ſtalks annually. Conſidered as flowery plants, they merit culture in every good garden, for they flower very ornamentally: the flowers are all monopetalous, ſalver-ſhaped, and collected into large conſpicuous bunches at top, continuing three or four weeks in beauty, but are rarely ſucceeded by ripe ſeeds in England.

They will proſper in any of the compartments of the pleaſure-garden, but are particularly well adapted for embelliſhing the principal borders, &c.

Moſt of the ſorts may be had at the public nurſeries; and the proper ſeaſon for removing them is in autumn when their ſtalks decay, or early in ſpring before they begin to ſhoot.

*Propagation of all the Sorts.*

The propagation of all the ſorts is by parting the roots, and by cuttings of their young ſtalks.

By Parting their Roots.—Autumn, when their ſtalks decay, is the beſt ſeaſon for this. Moſt of the ſorts afford a ſufficiency of offſets for propagation, which are to be ſeparated in the uſual way, not too ſmall; planting

The firſt ſpecies, *Phytolacca Decandria*, is the ſort the moſt commonly known and cultivated.

The propagation of both the ſpecies is by ſeed, ſowed in ſpring, in any bed or border of light earth, in ſhallow drills half an inch deep; and when the plants are come up three or four inches high, plant them out in moiſt weather, either in nurſery-rows till autumn, or at once into the places where they are to remain.

PINUS, Pine-tree, including the Fir-tree, &c.

This genus compriſes a grand collection of noble ever-green trees, and one deciduous kind, obtaining great height and magnitude, and of high value and worth, both for their beautiful growth to embelliſh ornamental plantations, and for their great utility as timber-trees. All of them cloſely garniſhed with ſmall linear aceroſe leaves; and monoecious, amentaceous, apetalous flowers, ſucceeded in the females by a ſcaly conic ſeed-veſſel, called a cone.

Claſs and order, *Monoecia Monadelphia*.

*Characters* ] CALIX, male and female flowers, ſeparate on the ſame plant, having ſcaly calices, the males being collected into ſcaly bunches, and the females into an imbricated cone, compoſed of oblong, rigid, permanent ſcales, each containing two florets. COROLLA, no petals, each floret conſiſting only of the fructifications. STAMINA, many monadelphous filaments having erect antheræ. PISTILLUM, a very ſmall germen, awl-ſhaped ſtyle, and ſimple ſtigma. PERICARPIUM, none, the ſeeds are lodged in the calycinal ſcaly cone, each ſeed is an oblong-oval nut, furniſhed with a membranaceous wing.

To this genus of *Pinus*, Linnæus has added *Abies*, the Fir-tree, *Cedrus* and *Larix*, the Cedar of Lebanon and Larch tree; which former botaniſts conſidered as ſo many diſtinct genera; but their generic characters being the ſame in every reſpect as the *Pinus*, they are now all ranged as ſpecies only of that genus: all the ſpecies of which, except the *Larix*, are ever greens, and riſe to a vaſt height, ſome above an hundred feet, with perfectly ſtraight ſtems; branching all around almoſt to the very bottom, moſtly in circular tiers or courſes, at diſtances one above another, ſpreading regularly like rays, in a ſomewhat horizontal poſition, ſhortening gradually towards the top, ſo as to give the head a conical form; which being very cloſely garniſhed with linear, or very narrow aceroſe leaves; they appear with a beautiful majeſtic grandeur, and are all ſo very hardy, that they proſper in almoſt any ſoil and ſituation; and are exceedingly well adapted both for ornamental and profitable plantations.

There are about ten or twelve diſtinct ſpecies: thoſe commonly called Pine-trees, are very diſtinguiſhable by ſight from the Firs, and both of theſe from the Cedar of Lebanon and Larch-tree. The leaves of the former (Pine-tree) come out by two, three, or five from the ſame point and ſheath: thoſe of the Firs come out ſingly, and the Cedar of Lebanon and Larch ariſe in bunches from the ſame point, thoſe of each bunch ſpread out every way.

*Pine Kinds; having two, three or five Leaves in each Sheath.*

There are about five or ſix ſpecies of theſe kinds, with ſome varieties; all hardy evergreen trees.

[1]PINUS *Sylveſtris*.

*Wild Pine-tree, or Scotch Pine, moſt commonly called Scotch Fir* ] Riſes with an upright, perfectly ſtraight ſtem, from about fifty to ſeventy feet high, or more, branching regularly all around; ſhort, ſmooth, dark-green leaves, two in each ſheath, but the primordial, or firſt leaves, come ſingly; and ſhort pyramidal acute cones.

It grows wild in gravelly woods, in many of the northern parts of Europe, and in great plenty in the Highlands of Scotland: hence the name *Scotch Pine*, &c.

There are vaſt plantations of this valuable tree in moſt parts of Scotland, where they beautifully enrich gentlemen's eſtates; in which we may ſee them proſper in all expoſures and ſoils, even on mountains and rocks, as well as in low moiſt ground; ſo may be cultivated to great advantage in any ſituation, and in places where many other trees, &c. would not thrive.

The timber of this tree is the common red, or yellow deal, of great value for all kinds of buildings.

*Variety.*] [2]PINUS *Pinaſter*.

*Pinaſter, or Foreign Wild Pine.*] Riſes with an upright, ſtraight ſtem, from fifty to ſixty or ſeventy feet high, ſending out large, horizontally ſpreading, yellowiſh branches, irregularly; very long, ſmooth leaves, two in each

each ſheath, but the primordial ones ſingly; and very long, pyramidal, acute cones.

[3]PINUS *Pinea.*

*Pinea, or Italian Stone Pine.*] Riſes with an upright, ſtraight ſtem, fifty or ſixty feet high, having a roughiſh bark; very long, ſea-green leaves, two in each ſheath, with the primordial ones ſingly and ciliated; and thick, roundiſh, turbinated, cloſe cones; having large, eatable kernels.

It is a native of Italy and Spain, where the kernels of the cones are in much eſteem for eating, and are very wholeſome, and good for colds and conſumptions.

[4]PINUS *Strobus.*

*Strobus Pine-tree, commonly called Weymouth Pine.*] Riſes with an upright, very ſtraight ſtem, an hundred feet high, or more, branching widely around, having a very ſmooth bark; long, ſlender, duſky-green leaves, by fives in each ſheath; and long, ſlender, looſe cones.

It is a native of North America, and firſt cultivated here on Lord Weymouth's eſtate, hence the name, *Weymouth Pine.* It is a tree of admirable beauty, and the prodigious height and magnitude which it attains, renders it of great value for its timber, and makes the moſt excellent maſts for ſhips.

[5]PINUS *Tæda.*

*Tæda, or Torch Pine, or Three-leaved Virginia Swamp Pine.*] Riſes with an upright ſtem, to a great height; having very long, ſlender leaves, by three in each ſheath; and large, long, looſe cones.

It grows naturally in low ſwampy grounds in Virginia and Canada.

[6]PINUS *Cembra.*

*Cembra, or Mountain Siberian Pine.*] Riſes with an upright ſtraight ſtem, forty or fifty feet high; having long, ſlender, very ſmooth, light-green leaves, five in a ſheath; and large cloſe cones.

The above ſix ſorts are the principal ſpecies of the Pine kind, but there are ſeveral varieties that belong to one or other of them, and are diſtinguiſhed in the nurſeries by the following names and deſcriptions.

Frankincenſe three-leaved American Pine—Virginia three-leaved, prickly-coned Pine—Virginia cluſter-coned Pine—Mugho two and three-leaved mountain Pine—Jerſey two-leaved prickly-coned Pine—Aleppo ſpreading-branched, two-leaved Pine—dwarf two-leaved American Pine.

*Fir Kinds (Abies) having Solitary or Singly-placed Leaves.*

There are about ſix ſpecies of theſe ſorts, with ſome varieties; all hardy ever-green trees.

[7]PINUS *Abies.*

*Abies, or Common Fir-tree, commonly called Norway Spruce Fir.*] Riſes with an upright ſtem, to a great height, branchy to the bottom; ſolitary, narrow, awl-ſhaped, ſharp-pointed, ſmooth, dark-green leaves, ſtanding two ways; and large cones, ſix or eight inches long, hanging downward.

*Variety.*] Long-coned Corniſh Fir, having longer leaves, and cones eight or ten inches long.

They grow naturally in Norway, and other northern parts of Europe, where they are commonly denominated Pitch-firs, becauſe in thoſe countries great quantities of pitch, &c. is extracted from them; their timber is the white deal, ſo greatly eſteemed by the joiners.

[8]PINUS *Canadenſis.*

*Canada Spruce Fir.*] Riſes with an upright, ſtraight ſtem, to a great height, branching from bottom to top; ſolitary, very narrow, ſhortiſh, obtuſe-pointed, dark-green leaves; and ſmall cloſe cones an inch long.

*Varieties.*] Canada white ſpruce——red ſpruce—and black ſpruce Fir; differing from each other principally in the colour of the cones. Theſe are all natives of North America.

[9]PINUS *Picea.*

*Picea, or Pitch-tree, commonly called Silver Fir.*] Riſes with an upright, very ſtraight ſtem, ſixty or ſeventy feet high, or more, branching thinly, having a ſmooth bark; ſolitary flat leaves, emarginated at top, marked with two ſilvery-white lines underneath; and has very long erect cones.

It grows naturally in the Alps, Germany, and in the Highlands of Scotland, and is remarkable for affording plenty of turpentine, &c.

[10]PINUS *Balſamea.*

*Balſamea, or Balm of Gilead Fir.*] Riſes with an upright, ſtraight ſtem, very branchy almoſt to the bottom; cloſely garniſhed with ſolitary, flat, obtuſe leaves, ſlightly emarginated at top, of a dark-green above, and marked with whitiſh lines underneath; and ſmall roundiſh cones.

*Variety.*] With variegated leaves.

This tree and variety are natives of North America; they are remarkable for their balſamic

### *Annual Kinds.*

There are two ſpecies of the annual kind proper for our collection, both exotics, but hardy enough to proſper in the open borders.

[3]PHYSALIS *Angulata.*

*Angular Winter Cherry.*] Riſes with an upright firm ſtem, dividing into numerous angular, ſmooth branches, growing two or three feet high; oval indented leaves; and at the axillas and ends of the branches ſmall white flowers, ſucceeded by large yellowiſh berries.

*Varieties.*] There are many varieties differing in ſome reſpect or other, but all retain the ſpecific difference of having angular branches, and ſmooth oval leaves.

[4]PHYSALIS *Pubeſcens.*

*Pubeſcent, or Downy Winter Cherry.*] Riſes with a ſhort ſtem, dividing low into numerous ſpreading branches, oblong, downy-viſcous leaves; and at the axillas greeniſh-yellow pendulous flowers; ſucceeded by large yellowiſh berries.

*Varieties.*] There are many varieties differing from one another in ſome peculiar mode of growth.

Both theſe ſpecies and reſpective varieties flower in June and July, and the berries ripen in autumn.

### *Shrubby Green houſe Kinds.*

Of theſe kinds there are but two ſpecies common to the Engliſh gardens, both of which are of a ſhrubby nature; and being exotics of warm countries require ſhelter of a green-houſe here in winter.

[5]PHYSALIS *Somnifera.*

*Somniferous Sicilian Winter Cherry.*] Hath a ſhrubby ſtem, branching three or four feet high, with the branches erect; oval, ſpear-ſhaped, downy, entire leaves; and at the axillas greeniſh-white flowers in cluſters; ſucceeded by ſmall red berries.

[6]PHYSALIS *Flexuoſa.*

*Flexuoſe Indian Winter Cherry.*] Hath a ſhrubby ſtem, branching four or five feet high, with long flexuoſe branches; oblong, almoſt cloſe-ſitting leaves; and at the axillas cluſters of ſmall greeniſh-yellow flowers; ſucceeded by purpleiſh berries.

Both theſe plants flower in June and July, and in favourable, warm, dry ſeaſons the berries ripen in autumn.

### *Hot-houſe Kinds.*

There are two ſpecies for the ſtove, both of them ſhrubby; and being natives of the hot parts of India, &c. require the conſtant aid of a ſtove to preſerve them in this country.

[7]PHYSALIS *Arboreſcens.*

*Arboreſcent, or Tree-like Campeachy Phyſalis.*] Hath a woody upright ſtem, dividing and branching out at top ten or twelve feet high; oval hairy leaves alternate below, and oppoſite above; and at the axillas almoſt ſolitary, yellowiſh revolute flowers; ſucceeded by ſmall red berries, in dark purple bladders.

[8]PHYSALIS *Curaſſavica.*

*Winter Cherry of Curaſſao.*] Hath an under-ſhrubby branching ſtem, riſing two or three feet high; oval, downy alternate leaves; and at the axillas ſmall, cloſe-ſitting, yellow flowers; rarely ſucceeded by berries in England.

The above eight ſpecies of *Phyſalis* are the chief ſorts at preſent in our gardens; they flower principally in June, July, and Auguſt: the flowers are ſmall, and conſiſt each of one rotated, or wheel-ſhaped, quinquefid petal; which in moſt of the ſpecies are ſucceeded by ripe berries incloſed in the calix, forming an inflated, or bladdery-like, coloured cover, opening at top and diſcover the fruit, and appears very beautiful in the autumn ſeaſon.

All the ſorts are retained in curious gardens as plants of ornament.

The herbaceous ſpecies, both of the perennial and annual kinds, ſucceed in the open ground; the former all the year, and the latter in ſummer, and make a pretty appearance, eſpecially in autumn, with their beautiful cherry-like red berries: obſerving, however, that as the ſecond ſort, *Phyſalis Viſcoſa*, is rather of a tender nature, ſome plants ſhould alſo be be kept in pots, to move to occaſional ſhelter of a garden-frame, &c. in froſty weather.

The ſhrubby kinds, both of the green-houſe and hot-houſe, muſt always be kept in pots for moving to ſhelter of thoſe conſervatories, and managed as other ſhrubby exotics of each collection.

### *The Propagation of all the Sorts.*

The propagation of all the ſorts is eaſily effected by ſeed; and the herbaceous perennials likewiſe by parting the roots; and the

ſhrubby

ſhrubby kinds of the green-houſe and ſtove alſo by cuttings; ſee each ſort under a ſeparate head, as follows:

Herbacious Perennial Kinds.—Theſe ſorts may be multiplied abundantly by ſeed, and by parting the roots. 1. By Seed.—Sow it in autumn as ſoon as ripe, or in ſpring, in a bed or border of light, dry ſoil, covering them half an inch deep; and when the plants are come up about two or three inches high, prick them out in nurſery-rows to ſtand till autumn, then tranſplant them where they are to remain. 2. By parting the Roots.——They multiply plentifully by the root, which may be parted any time in open weather from October till March; every ſlip having fibres at bottom, and a bud at top, will form a good plant.

Annual Kinds.—Both theſe ſorts are raiſed from ſeed annually in ſpring, in April, either in a warm border, or in a hot bed, to bring them more forward into flower: ſow the ſeed about a quarter of an inch deep; and when the plants are come up about three inches high, prick them out, which if alſo in a hot-bed for a month, it will forward them greatly; hardening them gradually to the open air, then tranſplant them in moiſt weather with balls, into the borders or places where they are to flower.

Green-houſe Kinds.—They are beſt propagated by ſeeds in a hot-bed in ſpring; and when the plants are a few inches high, prick them out into ſeparate ſmall pots, giving water and occaſional ſhade: afterwards manage them as other ſhrubby exotics of the green-houſe.

Cuttings of theſe ſorts may alſo be ſtruck by aid of a hot-bed, in ſpring or ſummer.

Hot-houſe Kinds.——They may be raiſed both from ſeed ſowed in pots, and plunged in a hot-bed; and by cuttings in ſpring or ſummer, planted in pots and plunged in any good hot-bed, or in the bark-bed of the ſtove, &c.

PHYTOLACCA, American Nightſhade.

It furniſhes principally herbaceous plants, one or two of which, hardy perennials, are retained as ornamental plants for the pleaſure-garden; riſing ſeveral feet high, adorned with large oblong and oval entire leaves; and cluſters of pentapetalous flowers.

Claſs and order, *Decandria Decagynia.*

*Characters.*] CALIX, none. COROLLA, five roundiſh, concave, ſpreading, coloured, permanent, reflexed petals. STAMINA, ten, eight, or twenty ſilaments, in different ſpecies, and roundiſh antheræ. PISTILLUM, an orbicular depreſſed germen, divided on the outſide, and terminated by ten very ſhort patent, reflexed ſtyles, having ſimple permanent ſtigmas. PERICARPIUM, an orbicular, depreſſed, ten-furrowed, decemlocular, berry, having a ſingle kidney-ſhaped ſeed in each cell.

There are four ſpecies, three herbaceous, and one ſhrubby; the moſt material of which are the two following herbaceous perennials.

[1]PHYTOLACCA *Decandria.*

*Decandrous Virginia Phytolacca, or Common American Nightſhade.*] Hath a very thick, fleſhy, divided, deeply-penetrating root; upright, ſtrong, herbaceous ſtems, dividing and branching ſix or ſeven feet high, covered with a purpleiſh bark; garniſhed with large, oblong, entire leaves, placed irregularly; and at the joints and axillas of the ſtalks long pedunculi, ſuſtaining each a large cluſter of ſmall decandrous and decagynous, purple flowers; ſucceeded by depreſſed ten-furrowed berries, ripening in autumn.

[2]PHYTOLACCA *Octandria.*

*Octandrous Mexican Phytolacca.*] Hath a fleſhy root; upright, ſtrong, herbaceous ſtem, dividing and branching two or three feet high; oval, ſpear ſhaped, veined leaves, placed irregularly; and from the ſides of the branches long pedunculi, terminated by ſpikes of cloſe-ſitting, octandrous and octogynous, white flowers; ſucceeded by depreſſed, ten-furrowed berries, ripening in autumn.

Both theſe ſpecies flower in July and Auguſt, the flowers are numerous in each cluſter and ſpike; each flower being compoſed of five permanent petals, &c. ſucceeded by berries, as deſcribed in the characters, furniſhing plenty of ripe ſeed in favourable autumns.

The juice of the berries ſtain linen and paper of a fine purple colour, but is not laſting.

Theſe plants are perennial in root, but annual in ſtalk, which riſing in ſpring, decays at the approach of winter.

They may be employed as plants of ornament in any of the compartments of the pleaſure-garden, but principally in a dry ſituation, where they will abide in root many years, particularly the firſt ſort, and ſhoot up new ſtalks every ſpring, and produce their flowers and fruit abundantly, and make a good appearance.

the ſtrongeſt ſlips where they are to remain to flower, and the ſmaller in nurſery-rows for a year to get ſtrength.

By Cuttings —If any ſorts furniſh but a ſparing ſupply of off-ſets from the roots, recourſe may be had to cuttings of the young ſtalks: May, when the ſhoots are but a few inches high, is the proper ſeaſon; cutting off a quantity cloſe to the ground, and trim off their tops; then plant them in a bed or border of good earth, or in large pots, ſeveral in each; giving water directly, repeating it often in dry weather, with occaſional ſhade from the ſun till rooted; or, if they are planted cloſe, and covered with hand-glaſſes it will forward their rooting; removing the glaſſes when they begin to ſhoot.

PHOENIX, Great Palm, or Date-tree.

It conſiſts of one ſpecies only, an evergreen tree of great height and ſingularity, an exotic of India, and retained here in our ſtoves for variety.

Claſs and order, *DioeciaTriandria.*

*Characters.*] CALIX, male and female ſpadiceous flowers on different plants, having an univalvular general ſpatha, protruding a branching ſpadix, compoſed of many florets, each with a three-parted perianthium. COROLLA, three oblong concave petals in the males, and in the females is compoſed of ſix parts. STAMINA, three very ſhort filaments, and oblong linear antheræ. PISTILLUM, a roundiſh germen, awl-ſhaped ſtyle, and acute ſtigma. PERICARPIUM, an oval, baccaceous, unilocular fruit, containing one nearly-oval, very hard ſeed.

The ſpecies is:

PHOENIX *Dactylifera.*

*Dactyliferous, or Date-bearing Palm; Greater Palm, or Date-tree.*] Riſes with an upright, ſtraight, undivided, branchleſs trunk, from fifty to an hundred feet high, ſtudded with rugged protuberances, the veſtiges of fallen leaves, and the middle filled with pith; no proper branches, but crowned at top with a vaſt columnar, ſpreading cluſter of pinnated branch-like leaves, ſix or eight feet long, compoſed of long, ſword-ſhaped, complicated, ſtiff, alternate folioles; and amidſt the leaves very long ſpadiceous cluſters of whitiſh flowers; ſucceeded in the female-plants by cluſters of large oval berries.

The berries of this tree are the dates of the ſhops, imported hither from Africa and the Eaſtern countries.

This ſingular tree, like the reſt of the Palm tribe, have no other branches than its large leaves, each of which being a compoſition of a leaf and branch, always ariſing from the top, and as the old leaves fall, the ſtem forms itſelf and advances in height; but although the leaves grow very tall in a few years, yet the ſtem advances but ſlowly, and can never be expected to arrive at a flowering and fruiting-ſtate in this country; it, however, merits a place in our hot-houſe collections for its ſingularity.

It muſt always be kept in pots of rich earth, and placed conſtantly in the ſtove; and if there plunged in the bark-bed, it will make the greater progreſs: obſerving to give proper waterings, and ſhift it occaſionally into larger pots.

The propagation of this plant is by ſeed, procured from abroad, which ſow as ſoon as poſſible, in pots of light rich earth, and plunge them in a tan hot-bed, or in the bark-bed in the ſtove; giving moderate waterings, they will ſoon come up, which, when a few inches high, prick into ſeparate ſmall pots, plunging them in the hot-bed, or in the bark-bed, as aforeſaid; where they may remain, giving frequent waterings, and ſhift them into larger pots, according as their progreſs of growth may require.

PHYLICA, Baſtard Alaternus.

This genus is compoſed of ſhrubby evergreen exotics of Africa, for the green-houſe collection; are of branchy growth, obtaining three or four feet ſtature, garniſhed with ſmall ever-green leaves; and cluſters of pentapetalous whitiſh flowers at the ends of the branches.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, many florets collected into a head, ſituated in one common receptacle, each having a monophyllous, five-parted, permanent cup. COROLLA, each floret is compoſed of five acuminated ſquamulæ ſituated in the baſe of the diviſions of the calix. STAMINA, five ſmall filaments under the ſquamulæ, and ſimple antheræ. PISTILLUM, a roundiſh, trilobed, trilocular, trivalvate capſule, having a roundiſh ſeed in each cell.

The moſt material ſpecies in the Engliſh gardens are the three following:

PHYLICA *Ericoides.*

*Heath-leaved Phylica.*] Hath a low ſhrubby ſtem, divided into many ſpreading branches, forming

forming a bushy head, about three feet high; closely garnished with very narrow, small, heath like, close-sitting leaves, in verticilli round the branches; and all the branches terminated by close clusters of white flowers; in autumn and winter.

[2]PHYLICA *Plumosa.*

*Plumose Phylica.*] Hath a low shrubby stem, dividing and branching about a yard high; narrow awl-shaped leaves, hairy at top; placed alternately on every side of the branches, and the branches terminated by close downy heads of fringed white flowers; in autumn and winter.

[3]PHYLICA *Buxifolia.*

*Box-leaved Phylica.*] Hath a shrubby erect stem, branching four or five feet high; small oval, obtuse, firm, smooth, sparsed leaves, downy underneath; and the branches terminated by small heads of greenish flowers; in autumn and winter.

All these species are durable in root, stem, and branches, and retain their leaves all the year.

They being natives of Æthiopia and other parts of Africa, are somewhat tender, requiring shelter here in winter, so must always be kept in pots, and placed among the greenhouse exotics, where they will effect a very agreeable variety at all seasons, and flower annually great part of autumn and winter; but do not produce seed in England.

Their propagation is chiefly effected by cuttings and slips of the young shoots.

In spring, about March or April, take off a quantity of young cuttings, or slips of the small shoots, plant them in pots of rich earth, which plunge in a hot-bed, or in the bark-bed in the stove; giving frequent waterings, and occasional shade from the sun, they will soon emit roots, and become proper plants fit for potting off separately in autumn.

Or young cuttings or slips planted any time in summer, particularly June and July, in pots, as above, and placed under a hot-bed frame, or covered close with hand-glasses, watered and shaded, they will also grow; but will not be so forward as those of the spring-planting.

PHYSALIS, (*Alkekengi*) Winter Cherry.

This genus consists of herbaceous and shrubby ornamental plants, for the pleasure-ground, green-house, and stove, mostly of upright, branchy growth; garnished with oblong, oval, and heart-shaped leaves; and monopetalous, rotaceous flowers.

Class and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is small, monophyllous, pentagonous, semi-quinquefid, swelling, and persistent. COROLLA, is monopetalous and rotated, with a very short tube, and the limb large, plicated, and quinquefid. STAMINA, five small awl-shaped filaments, having erect connivent antheræ. PISTILLUM, a roundish germen, filiforme style, and obtuse stigma. PERICARPIUM, a small roundish bilocular berry lodged in a large swoln, pentagonous, coloured calix, having many reniforme seeds.

There are about eight or ten species of this genus, consisting of hardy herbaceous perennials and annuals for adorning the pleasure-garden, and shrubby plants for the green-house and stove collections.

*Hardy Herbaceous Perennial Kinds.*

Of these kinds there are only two species for our purpose, both exotics of foreign countries, but hardy enough to live here in the open ground, one of which, *Common Winter Cherry*, hath been long a resident in our gardens.

[1]PHYSALIS *Alkekengi.*

*Alkekengi, or Common Winter Cherry.*] Hath long, creeping, perennial roots; many upright, jointed, herbaceous stems, a foot and a half high, branching at bottom; garnished with large, oblong, acute, entire leaves, by pairs from the same side of the stalk; and at the axillas, long slender pedunculi, terminated by white flowers; succeeded by round red berries, inclosed in the large inflated bladder-like calix.

[2]PHYSALIS *Viscosa.*

*Viscous Virginia Winter Cherry.*] Hath a creeping perennial root; many upright herbaceous stems, about a foot high, paniculated above; obtuse, repand, downy leaves by pairs; and at the axillas yellowish flowers; succeeded by greenish-yellow viscous berries.

Both the above species flower in June or July, and the berries ripen in autumn; those of the first sort resemble common red cherries, and exhibit a very ornamental appearance in autumn.

The berries of the first sort (*Alkakengi*) are used with success against the gravel and stone, and the heat of urine; and may be eaten raw, or boiled in milk and sweetened with sugar.

ſamic aromatic nature; the buds and leaves being remarkably fragrant, and any part of the tree being cut or broken, it will emit abundance of fine balſamic juice, or turpentine. Both the varieties aſſume a beautiful growth, and have great merit for all ornamental plantations.

The following is a variety of ſome of the Spruce kinds.

*American Hemlock Spruce Fir*—Riſes with an upright ſtem of moderate height, branching thinly, narrow obtuſe leaves, ranged two ways; and roundiſh cones.

*Cedar of Lebanon, and Larch Kinds, having Leaves in Bunches.*

There are only two ſpecies of thoſe kinds, one a celebrated ever-green tree, of great antiquity; the other a beautiful deciduous tree: both of them valuable for ornament, and for timber plantations.

11 PINUS *Cedrus.*

*Cedrus, or Cedar of Lebanon.*] Riſes with an upright trunk, obtaining conſiderable height and magnitude, branching horizontally around to a great width; cloſely garniſhed with narrow, acute, ſtiff leaves, in bunches from the ſame point; and largiſh, thick, cloſe cones.

It is a native of Mount *Libanus* in Syria; is very hardy, and proſpers here in almoſt any ſoil and ſituation.

This famous and curious tree is the loſty and ſpreading Cedar ſo greatly celebrated in ſcripture; to which many beautiful alluſions and compariſons are made; and is moſt certainly a tree of ſingular grandeur, after having arrived to ſome conſiderable growth, as it ſpreads its horizontal branches in the moſt agreeable form, very widely around; which agrees with the alluſion of the Pſalmiſt when ſaying—*She ſpreadeth her branches like the cedar-tree.* Mount Libanus ſeems to be the chief place of its natural or original reſidence; where, by accounts of travellers, there are ſtill a few old trees of prodigious magnitude remaining; but the cones having been diſperſed into many different countries, they have raiſed large plantations of the trees, and in ſome places are arrived to a conſiderable ſize; though in England there are only at preſent here and there a tree, that is of any conſiderable growth: they, however, are now raiſed abundantly in all the public nurſeries; and of late years numbers of the trees have been planted on many eſtates, for they will proſper in almoſt any ſoil and expoſure, and have great merit for all ornamental plantations; likewiſe as timber-trees: the wood of which being of ſuperior value.

There are ſaid to be ſome large trees ſtill remaining upon Mount Lebanon, whoſe trunks are thirteen yards in circumference, and the branches ſpreading forty ſpaces every way around.

It is ſaid the timber of this wonderful tree is proof againſt all putrefaction, and that it will continue ſound two thouſand years: it was greatly uſed in the building of Solomon's temple, and other ſacred ſtructures of antiquity.

12 PINUS *Larix.*—(*Deciduous.*)

*Larix, Larch-tree, or Deciduous Pine.*] Riſes with an upright, ſtraight, whitiſh ſtem, to a great height, ſending out long, ſlender, pendulous branches; long, fine, obtuſe-pointed, light-green leaves, in bunches from the ſame point, ſpreading open above; and with flowers of different colours in the varieties; ſucceeded by ſmall, cloſe, acute cones, an inch long.

It is a native of the Alps, Switzerland, and Italy, &c. which, though deciduous, is a tree of beautiful growth.

*Varieties.*] Common red Larch-tree, having reddiſh flowers and cones—white Larch-tree—black American Larch-tree—horizontal Larch-tree—dwarf Larch-tree.

All theſe twelve ſpecies of *Pinus* flower in ſpring, principally in April and May, but make very little ſhow: the flowers are univerſally monoecious, apetalous, and amentaceous, with the males collected into conic branches, and the females into cloſe cones, which gradually grow into real cones that produce the ſeeds, which will be ready for gathering in November.

All theſe twelve ſpecies are trees of the firſt magnitude and beauty; eleven of which are ever-greens, the twelfth is deciduous, and are all of hardy nature, ſo as to proſper in almoſt any ſoil and ſituation; having all great merit both to enrich our ornamental plantations, and moſt of them alſo as timber-trees; and for either purpoſe they may be employed in any expoſure in gardens, parks, or fields, or either in plains, or the ſides or tops of hills, and in woods and clumps of all ſorts; the Scotch Pine in particular is the hardieſt of all the ſorts; ſcarcely any country ſoil or ſituation comes amiſs to it, even on the tops of mountains and rocks where there is hardly any earth, and only crevices for their roots to ſtrike into; in ſhort, all the ſpecies of other *Pinus* in general poſſeſs nearly the ſame degree of hardineſs;

hardineſs; for though they may make the greateſt progreſs in deep and ſomewhat moiſt ſoils, yet they will alſo thrive tolerably both in clayey and ſandy ſoils, as well as in a gravelly, ſtony, and ſlaty ground; ſo that all the ſorts may be employed almoſt any where both for ornamental or profitable plantations: remarking, however, that the better the ſoil is, the greater progreſs they will probably make in their growth.

Therefore theſe fine trees are highly proper for plantations of all kinds, both for pleaſure and profit; and will greatly beautify and enliven the ſcene, as well as cauſe great variety among themſelves, by the difference of their leaves and cones; and as all the ſorts produce cones abundantly, furniſhed with plenty of ſeed, they may be eaſily raiſed in any quantity in the common ground. See their *Propagation*.

It is affirmed that plantations of theſe trees, beſides their being beautiful to behold when growing, and profitable as timber-trees, they render the air exceedingly wholeſome by their balſamic and aromatic exhalations, which they emit, and diffuſe widely around.

They are all very ſwift growers, as after being a few years old, they often ſhoot two or three feet in height in the courſe of one ſeaſon, moſtly performing the whole ſhoot by Midſummer; and always aſpire with one erect firm ſhoot in the middle, forming the ſtem, which at the termination of every year's ſhoot, ſends out a tier of branches circularly.

Conſidered as foreſt or timber-trees, they are of great value, as their timber is the principal wood uſed in our buildings, &c. but the principal ſorts for timber-trees are, the Scotch Pine—Pineaſter—Weymouth Pine—Swamp Pine——Stone Pine—Spruce Fir, and varieties—and Silver Fir. The timber of theſe ſorts is what we commonly call deal, and is of univerſal utility, particularly for all kinds of buildings, and innumerable other uſes: they are alſo of great value in ſhipbuilding, and are moſt excellent for maſts, in which they exceed all other trees yet known, particularly the Scotch Pine, Pineaſter, and Weymouth Pine; but the latter moſt of all, as it often grows to above a hundred feet high, with proportionable ſubſtance.

The Cedar of Lebanon and Larch-tree may alſo be employed in our plantations of timber-trees, for they will arrive to a great ſize in this country, as is evident by ſome old trees now in ſome gardens, &c.

Moſt of theſe trees are reſinous or gummy: of an agreeable aromatic ſmell, but bitter taſte.

It is from the Pine and Fir kinds that pitch, turpentine, and roſin are procured; being extracted from the growing trees, in the countries where they abound, and of which is made a very conſiderablk merchandize.

Moſt of theſe trees poſſeſs alſo very ſalutary medical properties. A decoction in milk of the ſeeds of Pineaſter, or the extremity of the young branches pulled in ſpring, is ſaid, with a proper regimen, to cure the moſt confirmed inveterate ſcurvy: the branches of the common Spruce Fir, are uſed by the Americans for making their ſpruce-beer.

All the ſpecies of theſe trees are propagated in great abundance in the public nurſeries, where they may be purchaſed in any quantity at moderate rates, or may be eaſily raiſed from ſeed, as directed under the article of their *Propagation*.

It is adviſable to plant out all theſe trees when they are young, not more than three or four feet high, or if younger the better; as they will root more freely, and make much greater progreſs.

The beſt ſeaſon for planting all theſe kinds of trees is autumn or ſpring, i. e. September, October, and November, for the autumnal planting, and February and March for the ſpring; tho' they may alſo all be removed with tolerable ſucceſs any time in open weather in winter, from September till March; but thoſe tranſplanted early in autumn will generally have taken root before winter comes on, and begin to eſtabliſh themſelves more firmly before the drought of the enſuing ſummer.

When intended to have ornamental plantations of theſe trees, they may be planted both in clumps and in continued plantations, ſometimes by themſelves, and ſome in aſſemblage with other trees of ſimilar growth, ſtationing the ever-greens principally with thoſe of that tribe; though, for the general part, they appear to the beſt advantage when diſpoſed by themſelves in various elegant clumps, and running plantations: obſerving to have a proper intermixture of the different ſorts, and allow a proper diſtance between the trees, that they may have room to ſpread their heads around diſtinctly, and be branchy quite to the bottom. Some trees of different ſorts may alſo be diſpoſed as ſingle objects, in lawns, parks, and other ſpacious openings.

But when deſigned to have any planted for timber-trees, they ſhould always be planted in continued plantations, and ſet pretty cloſe, ſo as to draw them more effectually up in height; for it is the length as well as the ſubſtance of this timber that greatly enhances its value; therefore they may be planted only four or five feet aſunder, and in ſeven years ſome of the weakeſt may be thinned out, and in two or three years after the thinning may be repeated; and ſo continue gradually thinning out the underlings, which will do for poles, ſpars, &c. and thus ſhould theſe plantations be thinned occaſionally till the principal trees deſigned for ſtanding are arrived at maturity, whereby they will aſpire to a prodigious height, with ſtems as ſtraight as an arrow.

After making any plantation of theſe trees either for pleaſure or profit, no farther trouble or expence is neceſſary, than keeping down large weeds, &c. whilſt the plantation is young, and fencing againſt cattle, for they do not require any trimming, as none of the branches ſhould by any means be lopped, which would not only ſpoil the beauty of the trees, but would retard their growth in proportion.

*Propagation and General Culture of all the Sorts.*

All the ſpecies of *Pinus* and varieties in general are propagated only by ſeed, which will grow freely in the common ground, either in beds or borders of light earth, or in pots or boxes of the like ſoil, in order for moving occaſionally to different ſituations at different ſeaſons; and the ſeaſon for ſowing all the ſorts is in March and April.

Moſt of the ſorts produce cones abundantly in our gardens and plantations, ripening in autumn and winter, containing plenty of ſeeds; obſerving to gather the cones in the proper time. All thoſe in particular that are of a looſe nature ought to be gathered early in winter, otherwiſe they are apt to open and diſſeminate their ſeeds; but thoſe that are compact and firm may hang longer, and be gathered any time about the middle or end of winter, or towards ſpring. The cones of moſt of the ſorts are alſo ſent us from the different countries where the trees abound; and are ſold at all the public nurſeries and ſeed-dealers at moderate rates; either the cones entire, or the ſeeds cleared from the cones: the method of taken out the ſeeds is as directed below.

It muſt be obſerved of getting the ſeed out of the cones, that as the cones are compoſed of numerous hard bony ſcales, very cloſely placed, having the ſeeds lodged between them; and that ſometimes the ſcales being almoſt united, eſpecially in ſome of the Pine kinds, Cedar of Lebanon, &c. and often ſo cloſely involve the ſeeds as they cannot be diſlodged without violence of breaking or ſplitting the cones open with an inſtrument; though thoſe of many of the ſorts will open readily by expoſing them before a fire, or to the Midſummer ſun, when the heat will cauſe the ſcales to open gradually, ſo as the ſeeds will eaſily ſhake out; but by waiting till ſummer for the heat of the ſun to open the cones, we loſe a year in the time of ſowing, therefore having procured a quantity of the cones in autumn or winter, they may be laid before a moderate fire, at ſome reaſonable diſtance, ſo as not to ſcorch the ſeeds: thus the ſcales will open, and the ſeeds may eaſily be beaten out of their cells; though ſome ſorts, particularly the Stone pine and Cedar of Lebanon cones are ſo cloſe and hard that the ſeeds cannot be diſlodged without violence, as above obſerved, and is generally effected either by breaking them with a vice, or by boreing a hole with an inſtrument up the middle of each cone, then having an wooden or iron peg of a proper ſize, drive it through the hole, which will ſplit and divide the cone ſo as the ſcales may be eaſily removed and the ſeeds taken out ready for ſowing.

With regard to the proper ſoil and ſituation in which to ſow theſe ſeeds, almoſt any common light ground in the nurſery will do, but give preference, where practicable, to a light ſandy loamy ſoil; and as to ſituation or expoſure it may either be any of the open quarters of the ſeminary, or in a ſomewhat ſhady border, in which they generally riſe ſtronger than in a full expoſure, unleſs the beds, &c. are ſhaded occaſionally in hot dry weather in ſunny days when the plants begin to come up.

The beſt ſeaſon for ſowing all the ſorts is March, but not later than the beginning of April.

Having, therefore, a proper quantity of ſeed ready; and the ground prepared by proper digging, and formed into one or more beds, three or four feet wide; take advantage of a dry day, and ſow the ſeeds, ſcattering them moderately thick all over the ſurface of the beds, and cover them half an inch deep with finely-broken light mould; or where

there

there are only a ſmall quantity to be raiſed, the ſeeds may be ſowed in large pots, or boxes of light ſandy loam, covering them the above depth; though this practice is more particularly neceſſary for the Cedar of Lebanon, in order to move the plants into the ſhade in ſummer, and to a ſunny warm expoſure in winter; but for the ſake of which convenience ſome ſow moſt of the ſorts in pots or boxes; and ſome, in order to forward them as much as poſſible, ſow them in pots, and plunge them in a moderate hot-bed juſt to bring up the plants. They, however, will all ſucceed tolerably in the full ground, eſpecially all the Pine, Fir, and Larch kinds; and moſt of the ſorts will come up in ſix or ſeven weeks after ſowing.

Having, however, ſowed the ſeed, the following little attendances are neceſſary in reſpect to the care of the ſeed-bed and young ſeedling plants. In the firſt place obſerve, that as theſe ſeedlings generally riſe out of the ground with the huſk of the ſeed on their tops, which being once obſerved by the birds, they will attack them from all parts, and if not prevented, will pull them up as faſt as they appear above ground; it is therefore adviſeable to defend them at this time, by ſpreading nets over the beds, &c. upon proper ſupport, to remain until the plants are all fairly come up, and have thruſt their huſks off their heads. In the next place, it will be of advantage at this time to give occaſional ſlight ſhade of mats, in hot ſunny days, to thoſe in a full expoſure. Give alſo occaſional very moderate waterings in dry weather; and keep them clear from weeds all ſummer. With the above care the ſeedlings will advance and form little ſlender plants by autumn following, though ſome probably will only be furniſhed with a few leaves at top, and juſt formed buds in the centre, ready to puſh next ſpring; others, more forward will likely have made a ſhort ſhoot by autumn: obſerving they are to remain in the ſeed-bed till a year old, they are hardy enough to ſtand the winter without any covering, except the Cedar of Lebanon, which if the weather proves ſevere, it may be proper to ſhelter occaſionally either with mats or a hot-bed frame: but all the others generally ſtand the ſevereſt froſt unhurt; and by ſpring following, all the ſorts ſhould be pricked out into nurſery-beds.

In ſpring following, therefore, the ſeedlings being one year old, they ſhould in general be pricked out from the ſeed-bed into nurſery-beds, and March or beginning of April is the proper time, obſerving to form beds for their reception four feet wide; then taking up the ſeedlings out of the ſeed-bed with all their roots as entire as poſſible, prick them in the new-prepared beds, in rows ſix inches aſunder; here let them have two years growth, when by the end of the ſecond ſummer they will have ſhot ſix inches, or more; then in ſpring after it is adviſable to tranſplant them in wider rows, alſo in the nurſery; obſerving in this ſecond removal to ſet them in rows two feet aſunder, and one at leaſt in the lines, as they are to remain here till of a proper growth for final tranſplantation; they will here ſhoot ſix or eight inches more in height the enſuing ſummer; and in another year they will puſh with much greater vigour, probably make a ſhoot of half a yard or two feet long; ſo that when about four or five years old they will be about a yard high; and if they ſtand a year or two longer they will be proportionably taller, and of full ſize for final tranſplantation.

Though it is moſt adviſable to tranſplant all theſe ſorts of trees finally when not above two or three feet high, as they generally take root ſooner, and ſet to growing more freely than trees of larger growth; for although moſt of the ſorts may be tranſplanted when ſix or eight feet high, yet trees of two feet moſt commonly make the greateſt progreſs.

However, when there is a neceſſity of retaining theſe trees longer in the nurſery, it will be of advantage to tranſplant them every two years, whereby the roots will be kept ſhorter, and throw out a great many fibres, ſo as to admit of being removed with ſafety, for without the precaution of removal, trees of ſome years ſtanding would extend their main roots to a great diſtance, and be unfurniſhed with fibres, in which caſe large trees would be very liable to fail; but in the other method, trees of ſix or eight feet ſtature are ſometimes removed with tolerable ſucceſs; though the tranſplantation of ſuch large trees of theſe kinds ſhould only be practiſed where an immediate ſhew is required in ornamental plantations.

But I ſhould adviſe, for the general part, that moſt of the ſorts, the Pine and Fir kinds in particular, have their final tranſplantation when not more than two or three feet high, as before hinted, eſpecially where any conſi-

derable plantation is intended, more particularly if deſigned as foreſt-trees. I have, indeed, aſſiſted in planting many thouſand of the Scotch Pine, and others, when little more than a foot high, on the ſides of hills and waſte grounds, without any previous preparation of the ſoil, than juſt making an aperture, or hole for each plant, and frequently only making a ſlit with the ſpade for the reception of each, leaving them to ſhift for themſelves, and ſecuring the boundaries of the ground againſt cattle: moſt of them have ſucceeded; though, in general, plants about two feet or a yard high, are an eligible ſize for any plantation.

The ſeaſon for making plantations of theſe ſorts is autumn or ſpring, or even in winter during mild weather, as already noticed.

In taking up all theſe kind of trees for any plantation, obſerve with particular care to raiſe them with all the roots as entire as poſſible: preſerve alſo their tops perfectly entire, likewiſe all their branches, and in that ſtate let them be planted; only previouſly with your knife trim any broken or very ſtraggling part of the root.

With regard to the diſtribution, or arrangement in the different plantations, and mode of planting, they are as follow—Thoſe deſigned for embelliſhing the ſhrubbery compartments, and for ornamental plantations in general, may be diſpoſed both in aſſemblage with other trees, and to form clumps, and continued plantations occaſionally of themſelves. But thoſe intended as foreſt-trees ſhould generally be diſpoſed alone in conſiderable plantations: and, as to the method of planting them, it is the ſame as for other hardy trees, ſee PLANTING: obſerving however, where large plantations in out-grounds are intended either for pleaſure or profit, there will not be any great neceſſity for a previous preparation of the ſoil, with reſpect to digging or ploughing, only juſt to dig a hole for each tree: the ſame rule may alſo be obſerved in planting clumps of them in lawns, parks, and other graſs-ground. Obſerving, that thoſe deſigned principally for ornament, ſhould be diſpoſed at ſuch diſtances as their branches may extend freely every way, for the beautiful diſplay of the head is a great merit in theſe trees in pleaſurable plantations; but thoſe intended for timber plantations, may be planted only four or five feet diſtance, in order that they may draw one another up ſtraight and tall more expeditiouſly, and to admit of a gradual thinning after a few years growth, for poles, &c. as already obſerved.

After having their final tranſplantation, they require but very little more trouble, only obſerving to clear them, while young, from overbearing weeds; and if any large trees, five or ſix feet high, or upwards, are planted, it is proper to ſupport each tree with a ſtake, to ſecure them againſt the power of tempeſtuous winds, till firmly rooted.

Let all the ſorts take their own natural growth; being careful to preſerve their tops perfectly entire, to ſhoot up as faſt as poſſible; ſuffering them alſo to branch out in their own way; for no pruning is wanted, unleſs the lowermoſt tier of branches in any particular trees ſhould be thought too low and ſtraggling, when theſe may be occaſionally trimmed, cutting cloſe to the ſtem; but prune no further, for it ſhould be very ſparingly practiſed to theſe reſinous trees, as lopping the branches contributes to retard their growth, as well as impair their beauty. Indeed in large foreſt plantations, where the trees are arrived to a large growth, it is cuſtomary to lop their lower branches gradually for faggots, according as they begin to decay, for where theſe trees ſtand cloſe, the upper branches generally kill thoſe below, ſo that the lower tiers decay gradually and ſucceſſively one tier after another; and in which caſe, theſe decaying lower branches may be lopped by degrees in winter.

When the plantations deſigned for timber-trees have had from eight to ten or twelve years growth, it may be proper to begin to thin them, obſerving the rules before laid down: thoſe thinned out will ſerve for many ſmaller purpoſes, being careful in thinning to leave a ſufficiency of the fineſt plants ſtanding at proper diſtances, to grow up for timber.

PISTACIA, Piſtachia-nut, or Turpentine-tree.

This genus conſiſts of the tree and ſhrub-kind, furniſhing hardy deciduous trees for the ſhrubbery, and ever-green ſhrubs for the green-houſe, all of them of upright growth, riſing twenty or thirty feet high, garniſhed with pinnated and trifoliate leaves, and dioecious, amentaceous, apetalous flowers, ſucceeded by drupaceous berries, furniſhed with oval nuts; which in ſome ſpecies are eatable.

Claſs

Claſs and Order, *Dioecia Tetrandria.*

*Characters.*] CALIX, male and female flowers on diſtinct trees, the males collected into looſe, ſparſed amentums, compoſed of ſmall ſcales, each having one floret, furniſhed with a very ſmall, five-parted perianthium; and the females in cluſters, with ſmall trifid cups. COROLLA, ſmall florets without petals. STAMINA, four very ſmall filaments, having large, oval, tetragonous, erect, petalous antheræ. PISTILLUM, an oval germen, three reflexed ſtyles, with thick hiſpid ſtigmas. PERICARPIUM, an oval berry-like drupe, having an oval ſmooth nut.

There are five ſpecies, four of which are hardy ſhrubs, moſtly deciduous; the other is a tender ever-green for the green-houſe.

*Hardy Kinds.*

Theſe kinds, however, though denominated hardy, are rather tender whilſt young, at leaſt thoſe raiſed from ſeed, requiring ſhelter of a green-houſe or garden-frame, in winter, till four or five years old, and are become a little woody.

[1]PISTACIA *Vera.*

*True Piſtachia-tree.*] Riſes with an upright ſtem, branching twenty or thirty feet high, covered with a ruſſety cracked bark, but the younger branches ſmooth; large pinnated leaves, of two or three pair of oval recurved lobes, terminated by an odd one; and from the ſides of the branches ſmall greeniſh flowers in amentums and bunches, ſucceeded in the female trees by cluſters of oval fruit, containing large eatable nuts.

It is a native of Perſia, Arabia, and Syria, from whence the nuts are brought annually, for they rarely ripen here in our gardens, and are ſold in the ſhops by the name of Piſtachia-nuts.

PISTACIA *Terebinthus.*

*Terebinthus, or Turpentine-tree.*] Riſes with an upright branchy ſtem, about thirty feet high, having a dark bark full of cracks; pinnated, dark-green, alternate leaves, of three or four pair of oval-ſpear-ſhaped lobes, terminated by an odd one; and ſmall greeniſh flowers.

It grows naturally in Italy and Spain, and from its trunk flows the true Turpentine, but that of ſome of our Pine-trees is commonly ſubſtituted.

[3]PISTACIA *Trifolia.*

*Trifoliate Piſtachia-tree.*] Riſes with an upright branchy ſtem, between twenty and thirty feet high, having a rough brown bark; trifoliate or three-lobed, dark-green leaves; and ſmall greeniſh flowers.

[4]PISTACIA *Narbonnenſis.*

*Narbonne Turpentine-tree.*] Riſes with an upright branchy ſtem, about twenty feet high, having a whitiſh bark; pinnated leaves, moſtly of three or five roundiſh lobes; and ſmall greeniſh flowers.

The firſt ſort is the hardieſt of all the above four ſpecies, and the third and fourth are the tendereſt, and are often kept here in the green-houſe collections, alſo ſometimes the common Turpentine-tree; but they may all be gradually hardened to bear the full air the year round.

*Green-houſe Kinds.*

[5]PISTACIA *Lentiſcus.*

*Lentiſcus, or Maſtick-tree.*] Riſes with an upright branchy ſtem, fifteen or twenty feet high, having a greyiſh bark; abruptly pinnated leaves, of three or four pair of ſpear-ſhaped lobes, not terminated by an odd one; and ſmall greeniſh flowers.

From this ſpecies and variety is collected the Maſtick of the ſhops.

*Variety.*] Narrow-leaved Lentiſcus.

All the above five ſpecies of *Piſtacia* flower generally in April; they are univerſally dioecious, or male and female upon ſeparate trees; are ſmall and without petals, with the males collected into amentums, and the females in bunches, moſtly of a greeniſh colour, ſo make no ſhow; and thoſe of the females are ſucceeded by cluſters of fruit, ripening to a blue or blackiſh colour, incloſing the nuts, but theſe never ripen in England.

With reſpect to the merit of thoſe trees in our gardens, obſerve as follows:

The firſt four ſpecies are proper to increaſe the collection in curious ſhrubberies, obſerving as they are of ſomewhat tender quality, ſhould have occaſional ſhelter from froſt whilſt young, ſo ſhould be kept in pots till three or four years old, ſo as they have obtained a little ſtrength, and become woody, they may be turned out into the open ground, in a dry warm ſituation; and may alſo retain ſome in pots, to have occaſional ſhelter among the green-houſe plants in ſevere winters, more particularly the *Trifoliate* and *Narbonne* kinds; which two ſorts, if ſheltered in winter, will often retain their leaves great part of the year; and being more tender than the firſt and ſecond, they are in many gardens retained as green-houſe plants. All theſe four ſorts, however

however denominated hardy, may be gradually hardened to bear the full air the year round, as aforeſaid.

The fifth ſort, *Lentiſcus*, is a pretty evergreen, of a tenderer nature than the other four, ſo muſt have ſhelter, all winter, of a green-houſe; in which collection it highly merits culture, as it effects a diſtinguiſhable variety at all ſeaſons of the year.

*Their Propagation, &c.*

The propagation of all the five ſpecies is principally by ſeed; and ſome ſorts alſo by layers.

By Seed.—The nuts are the ſeed, which of all the ſorts are procured from abroad annually, and may be obtained at moſt of the nurſeries, &c. obſerving they all require the aid of a hot-bed. Let them be ſowed early in ſpring, in pots of light earth, half an inch deep, and plunge the pots in a hot bed, juſt to bring up the plants: when this is effected, be careful to admit a large portion of freſh air daily and by degrees harden them to it fully in June, giving frequent refreſhments of water all the ſummer; and in autumn remove the pots to the ſhelter of a hot-bed frame, or a green-houſe, to remain all winter; then in ſpring following plant them out into ſeparate ſmall pots, which if directly plunged in a moderate hot-bed it will greatly facilitate their rooting, and ſet them forward; but when they begin to ſhoot, harden them to the full air, ſtill continuing a proper ſupply of watering; and in autumn remove them again to a frame or green houſe, for the winter; which care muſt be repeated to all the ſorts till they are three or four years old, as aforeſaid; ſhifting them occaſionally into larger pots. After this, moſt of the four hardy kinds may be turned out into the ſhrubbery compartments to remain; but the *Lentiſcus* muſt ſtill be continued in pots to have ſhelter in winter with other green-houſe exotics.

By Layers.——Moſt of the ſorts may be tried by this method; but the *Lentiſcus*, in particular, is very commonly propagated by layers. Chuſe the moſt conveniently ſituated young ſhoots, which lay in ſpring by common laying, and they will be moſtly well rooted by the following autumn; when they ſhould be taken up and potted ſeparately, and managed as the ſeedlings.

PISTILLUM, the Piſtil, or Pointal of the flower, or female organ of the generation of plants, riſing in the centre of the flower like a column, conſiſting of the germen, ſtyle, and ſtigma.

1. The *Germen* forms the baſe of the *Piſtillum*, and is the ſeed-bud, or rudiments of the ſeed-veſſel, or fruit, and ſupports the ſtyle, elevated like a pillar in the middle of the flower. See GERMEN.

2. The Style (*Stylus*) ſtands upon the ſummit of the germen, elevated like a column, and correſponds to the *vagina* in animals, being generally ſomewhat hollow like a tube, tho' the tubular parts are often ſo fine as to be ſcarcely perceptible, ſerving to tranſmit the effluvia of the ſecundating duſt, or *Pollen*, through into the heart of the germen, or ſeed-bud, for the purpoſe of impregnating the ſeeds, and is terminated by the ſtigma. See STYLUS.

3. The Stigma is the ſummit or head of the ſtyle, appearing frequently like a knob or head, and when there is no ſtyle, it adheres to the ſummit of the germen; and its uſe is to receive the male-duſt from the antheræ; thence tranſmiting its vapour through the *vagina*, or ſtyle, aforeſaid, into the heart of the ſeed-bud, for the purpoſe of impregnation. See STIGMA.

Each of the above parts of the *Piſtillum* is more particularly explained under its reſpective head.

PISUM, the Pea.

This genus conſiſts wholly of hardy herbaceous plants, one ſpecies of which, the *common Pea*, an annual, is the parent of all the numerous varieties of Peas cultivated in our gardens and fields for common uſe, the merits of which, as eſculents, are univerſally known; all of which riſe with long, ſlender, cirrhoſe-climbing ſtalks; garniſhed with cirrhoſe-pinnated leaves, and papilionaceous flowers; ſucceeded by that ſort of ſeed-veſſel called a legumen, or pod, filled with Peas, the eatable part of the plant.

Claſs and Order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, acutely five-parted and permanent. COROLLA, is papilionaceous, conſiſting of a broad heart-ſhaped, reflexed, indented ſtandard, ending with a point; two ſhort, roundiſh, connivent wings, and a ſhorter, compreſſed, ſemi-lunulated keel. STAMINA, ten diadelphous filaments, crowned by a roundiſh antheræ. PISTILLUM, an oblong compreſſed germen, a triangular, riſing, membranaceous ſtyle, and oblong hairy ſtigma. PERICARPIUM, a large, long, bivalvular pod, ending

in a point, containing one row of roundiſh ſeeds or Peas.

The principal diſtinction between this genus and *Lathyrus*, (Everlaſting Pea, &c.) is, the ſtyle of this is triangular, and that of the Lathyrus is plane. See LATHYRUS.

There are four ſpecies of this genus; two only of which have merit for our purpoſe; though there is only one ſpecies conſidered as an eſculent for general culture, which is the *Common Cultivated Pea*, compriſing, however, numerous varieties; for all the ſorts of garden and field Peas are varieties only of one ſpecies; but whether the common white Pea of our gardens, or the grey field Pea be the original kind, is uncertain. The other ſpecies alluded to is conſidered principally as a flowery plant belonging to the tribe of hardy annuals.

*Cultivated Kinds.*

PISUM *Sativum.*

*Common Cultivated Pea.*] Riſes with long, ſlender, trailing ſtalks, by claſpers upon ſupport, from two to ſix or eight feet high; pinnated, cirrhoſe leaves, of about three pair of lobes, terminated by cirrhi, or tendrils, and have taper foot-ſtalks, with roundiſh, indented ſtipula below; and at the axillas long pedunculi ſupporting many flowers, &c.

*Varieties.*] Common white Pea—common grey field Pea; each of which compriſing many varieties.

Each of theſe two principal varieties of this ſpecies, *Piſum Sativum*, compriſe numerous others, particularly the white ſort; and new ones are obtained almoſt every year, in one place or other, differing from one another in ſome little particular, either in their growth, manner, and time of bloſſoming and bearing, ſize and form of the pods and peas, together with their quality for eating; and ſeveral other little properties or ſingularities, all of which are accidental varieties, riſing from one another; for ſuppoſe we were to cultivate only any one of the varieties, we by obſervation will find plants varying from the original ſort, ſometimes probably for the better, and ſometimes worſe; but the firſt only is to be regarded; and it is by obſerving this, that curious perſons have encreaſed the valuable varieties, when by examining their crops, find one plant very different from all the reſt, or any other known ſort, either by its bloſſoming and bearing earlier, or ſome other valuable ſingularity, carefully mark it, and preſerve all its produce for ſeed; which being ſowed ſeparately for two or three years, or till having multiplied them ſufficiently to be diſtributed, they are ſent into the world as a new ſort, bearing the name probably of the place, or perſon who firſt obtained them, ſuch as the Charlton Pea, &c. Thus the different varieties of Peas are obtained, and each reſpective variety multiplied for public ſupply: ſome of which varieties differ very materially from one another, either by their early bearing, or by their larger growth, or the like, though ſome reputed varieties differ ſo immaterially that the difference is hardly diſtinguiſhable. And it is to be remarked of all theſe acquired varieties, that although ſome are tolerably permanent, yet without proper care in ſaving the ſeed of each ſort ſeparate, they will all gradually degenerate to one another, or to the common white, or grey kind; ſo that it would in a manner be impoſſible to pretend to ennumerate all the varieties of Peas, or to give any particular deſcription of the different ſorts; therefore we ſhall only exhibit a liſt of the principal varieties that are at preſent the moſt commonly known; which, though pretty many, there are not above five or ſix that have merit for general culture; ſome of which are moderate growers, and early bearers, commonly called Hotſpurs; others are large growers, and come later into bearing.

*Hotſpurs, or ſmaller forward Kinds.*] Early Charlton hotſpur Pea—early golden hotſpur, an improved variety of the Charlton kind—Nicholas earlieſt hotſpur, an improvement of the golden ſort—Maſters hotſpur Pea—Reading long hotſpur Pea—dwarf hotſpur Pea: with ſeveral other reputed varieties of leſs note, that hardly differ in any thing from the above ſorts.

All the above are moderate growers, riſing upon ſticks only, three or four feet high: and the dwarf Pea ſcarcely half ſo much: they are all excellent bearers, producing moderate ſized well filled pods; but the firſt four ſorts differ very little from one another, only in ſome bearing a little earlier than others: the golden kinds are the preſent earlieſt bearers, and in the moſt eſteem for the forward crops, though any of the hotſpur ſorts are proper both for the early and firſt general crops, or in ſhort, for the principal crops during the whole pea-ſeaſon, for they are rather ſweeter eating Peas than the larger kinds: the Reading hotſpurs in particular have great merit to make

make a principal ſhare in the general crops, they being remarkable bearers, and produce fine long pods; and the dwarf Pea is particularly valuable for early crops in frames, &c. or a few may be ſowed occaſionally in the open ground both for early and later crops, for it is a remarkable bearer for its ſize; but not proper, however, for any general crop. By different ſowings of the hotſpur kinds from October or November until ſpring, they will furniſh a daily ſupply of peas from May until Auguſt, or till ſucceeded by the following larger kinds.

*Larger-growing late Kinds*] Large marrowfat Pea—dwarf marrowfat Pea——large ſugar Pea, having very large bowed pods—dwarf ſugar Pea—Spaniſh Moratto Pea——green nonpareil Pea—rouncival Pea—green rouncival Pea—white rouncival Pea.

Theſe large kinds moſtly aſſume a ſtrong growth, and will riſe upon ſupport five or ſix, or even ſeven or eight feet high, and produce fine large pods in tolerable plenty; the Marrowfats and Spaniſh Morattos in particular bear abundantly, and are profitable both for family uſe and market; but the Marrowfats are moſt eſteemed for the main crops. Obſerving, all theſe large kinds are proper to ſow chiefly in ſpring, from January and February until May, to ſupply the table in July and Auguſt; and by ſowing late in May and in June, a ſucceſſion may be continued from the beginning of July until near Michaelmas.

*Other Varieties of leſs Note*] Crown or roſe Pea, riſing with very thick ſtalks, bearing its bloſſom and pods at top, in a large umbellate cluſter, valued more for curioſity than profit—painted lady crown Pea—ſickle podded Pea—egg Pea—cluſter Pea——large grey Pea——crooked grey Pea: with ſome others of leſs note.

Great as the above number of varieties of Peas are, they are all the offſpring of one ſpecies, that have ariſen at different times by chance, and been encreaſed by good culture.

The following ſpecies is chiefly valued as a flowery plant.

²PISUM *Ochrus.*

*Ochrus, or Winged Pea.*] Hath angular ſtalks growing about a yard long; diphillous or two-lobed leaves, having membranaceous, decurrent, winged foot-ſtalks; and pedunculi ſuſtaining one yellow flower; ſucceeded by oblong pods, containing roundiſh compreſſed Peas.

Both the above ſpecies of *Piſum*, together with all the numerous varieties of the common Pea, are herbaceous annuals; riſing from ſeed in winter and ſpring, flower and yield their produce in ſummer, and totally periſh in autumn following; ſo that a freſh ſupply muſt be raiſed annually from ſeed; and that to have a regular ſupply of the varieties of the common Pea for uſe from the earlieſt part of ſummer until Michaelmas, ſeveral different ſowings from October or November until May or June are neceſſary; for a crop of Peas continues but about a fortnight in full bearing; but by a repetition of ſowings once in three weeks or a month during the above period, a conſtant ſucceſſion is continued five or ſix months.

### *General Obſervations.*

All the ſorts are hardy, and thrive in the open ground in almoſt any common ſoil of a garden and field: obſerving the early ſowings ſhould generally be in a warm dry ſituation, and the general and later crops in any open expoſure.

They are all of trailing growth, though of the cirrhoſe climbing kind, for being furniſhed with *cirrhi*, or tendrils at the ends of their leaves, that catch hold of any neighbouring buſhes or ſticks, they thereby climb and ſupport themſelves erect, and mount ſeveral feet high; which indicates that though they are procumbent or trailing plants, yet by being furniſhed with claſpers, nature ſeems to have deſigned that the generality of them ſhould climb and raiſe themſelves from the earth: therefore in their culture it will be found advantageous to allow them ſupport of ſticks, which may be practicable enough for moderate quantities, in places where loppings of trees, &c. can be obtained in plenty; and as the Peas are cultivated in rows, by placing a range of ſuch ſticks along each row, the plants will readily catch hold and aſcend to their tops, and bloſſom as they advance in height; and both bloſſoms and pods will be conſiderably more abundant, and continue longer than thoſe that are ſuffered to trail on the ground.

They are cultivated always in rows, by ſowing them in drills, from two to four feet aſunder; that being not only the moſt commodious method of ſowing, but alſo for the

the nature of growth of the plants, as well as for admitting to do the neceſſary work, and to gather the produce. See the *Propagation*, &c.

Peas are a moſt uſeful and profitable eſculent, valuable both to ſupply our tables with their produce, young and green, all the ſummer, and alſo to be dried when ripe, and preſerved for winter, when they are moſt excellent for many purpoſes, as for Peas-ſoup, Peas-pudding, &c.

The general ſeaſon of green Peas for uſe is principally June, July, and Auguſt, by ſowings from December or January until May; but by ſowings ſo early as October and November, and continuing a monthly repetition of ſowings, as before hinted, we often have Peas daily from the beginning of May to the end of September.

The principal ſorts of Peas that merit eſteem for general culture, are the early Charlton, Golden, and Reading Hotſpurs; the Marrowfats, Spaniſh Morattos, and Rouncivals; all of which are great bearers, and exceeding fine eating Peas; but where there is large ſcope of ground, curious perſons may raiſe as many of the ſorts as may be convenient: I, however, have obſerved, that three or four different ſorts were always fully ſufficient for the general crops; with which the table have been as plentifully ſupplied during the whole ſeaſon of Peas, as if all the varieties had been raiſed, and with much leſs trouble.

Of the ſmaller kinds, I ſhould adviſe the Charlton or Golden Pea, both for the early crops, and for the firſt general crops, by different ſowings, at a month or three weeks interval, from October or November until ſpring, to ſupply the table with green Peas from May until July or Auguſt; but indeed all the Hotſpur kinds are excellent for general culture almoſt the whole ſeaſon of Peas, but are peculiarly adapted for the early or forward crops, becauſe they come into bearing ſooner than the larger kinds by a fortnight, if both ſorts are ſowed on the ſame day. The earlieſt Golden Hotſpurs are the beſt to begin with for the earlieſt crops, repeating two or three ſowings at intervals, as above ſuggeſted; afterwards may be ſown any of the other Hotſpur kinds, particularly a good ſhare of the Reading or long Hotſpurs for the general crop, as being moſt excellent bearers, producing fine long pods: remarking, that the Hotſpur kinds in general may be ſowed any time from October until April or May, at intervals of a month, three weeks, and fortnight; that is, the ſowings from October until Chriſtmas, once a month or three weeks will be often enough; and from Chriſtmas until the beginning of March once a fortnight or three weeks; and from March till May repeat the ſowings once a fortnight at leaſt: by which intervals of ſowing you will have a plentiful daily ſupply all ſummer long; each crop continuing in bearing but a fortnight or three weeks, ſo the different ſowings regularly ſucceed one another.

I have, of the early crops of Hotſpurs that come into bearing ſoon in May, let the gleanings ſtand for ſeed, which ripening early in June, have ſowed them directly, and gathered a crop of peas from them the ſame year in Auguſt and September.

And of the large kinds, I ſhould prefer principally the Marrowfats, Spaniſh Morattos, and Rouncivals; to be ſowed in ſpring, &c. for the general later crops, i. e. to bear in July, Auguſt, and September; but would give preference to the Marrowfats, particularly the dwarf kinds: for the chief crops, next to theſe, the Spaniſh Morattos, then the Rouncivals; the latter of which, though they may be ſowed at any time in common with the two former, yet I would alſo adviſe to uſe theſe ſorts principally for the late crops, as they generally endure the drought of ſummer the beſt; but any of theſe large kinds that are moſt approved, may be ſowed any time from January or February until the end of May, or beginning of June; and where variety is in requeſt, ſome of each ſort may be ſowed, but moſt of all of the Marrowfats, beginning with the dwarf kinds firſt, which indeed is rather preferable for continuance than the large Marrowfats, as this ſort requires very great room to grow, and unleſs they have very tall ſticks to run upon to their full length, do not ſucceed well; but with this aſſiſtance, however, it bears wonderfully; ſo that where there is every convenience, it is proper to ſow both theſe ſorts; and to have a regular ſucceſſion of any or all theſe large ſorts of Peas, continue ſowing a few every fortnight, or three weeks from January or February until the end of May or beginning of June, as above obſerved, though in April and May the ſowings ſhould be every fortnight at leaſt; and I would adviſe the late ſowings to be chiefly of the Rouncival kinds: thus by repeated ſowings you will have a plentiful daily ſupply of theſe large Peas from the beginning of July until the end of September, even

ſometimes, in favourable ſeaſons, until October.

As to the mode of culture, Peas in general ſhould be cultivated in rows, as we obſerved before, by ſowing the ſeed in drills drawn with a hoe, from one to two inches deep, allowing abundance of room between the ſeveral lines or ranges, for the free admiſſion of ſun and air, as well as for performing the neceſſary culture, and room to go between to gather the produce without breaking down the plants. Allow therefore the ſmaller kinds not leſs than two feet or two and a half, between the rows, but if intended to give them ſticks to run upon, allow three feet at leaſt, or rather three and a half between the lines in rich ground; and the larger kinds ſhould be allowed a yard between the rows even when no ſticks are intended; but if deſigned to ſtick them, four feet is requiſite, or four and a half for the largeſt ſorts, ſuch as the large Marrowfats and Rouncival kinds. For it is moſt neceſſary, where practicable, to allow all the ſorts ſticks: placing a range of any ſort of tall branchy ſticks, or bruſh wood, along each row of plants, when about half a foot high, for them to climb upon for ſupport, whereby they will produce double the quantity of Peas, as when ſuffered to trail on the ground. This, however, though not very practicable where large quantities are raiſed in fields for the ſupply of market; yet for moderate quantities in private gardens, where ſticks can be readily obtained, it ſhould never be omitted, as the advantage will be more than double.

Obſerve always to allow more room by a foot, between the rows for thoſe crops that you deſign ſhall have ſupport of ſticks, than thoſe that are not; for Peas that have ſupport always grow ſtrongeſt, and if they have not proper room, the plants of the different lines will interfere, and both interrupt the growth of each other, exclude the neceſſary influence of the ſun and air, and not admit of room to gather the Peas without breaking the plants to the great diminution of the crops; but give them proper room and ſupport, and you will reap the advantage in proportion.

But when intended to allow Peas ſupport of ſticks, I have often ſowed them in double rows, with very wide intervals between, that is, beginning at one end of the ground, ſow two rows together, only a foot aſunder; then, if for the Hotſpur kinds, leave a ſpace of four feet, or if the large kinds, five feet, and ſow two more rows a foot apart; then allow another wide ſpace, and ſow other two cloſe rows, &c. and ſo proceed throughout: by this practice you have the ground equally filled as if the rows were ſingle and cloſer; and by the abundant room in the wide ſpaces, it admits all the advantage of ſun, air, and of gathering the produce freely without incommoding the plants.

Seed Peas of all the ſorts are ſold at all the ſhops and nurſeries at moderate rates, commonly by meaſure, as by the buſhel, peck, &c. or in ſmaller quantities for private gardens, by the quart or pint.

*Their Propagation and General Mode of Culture.*

As to propagation, all the ſorts are raiſed from ſeed, i. e. the Peas ſowed annually, the plants, being but of one ſeaſon's duration, an annual repetition of ſowing is conſequently neceſſary; and as thoſe of one ſowing continue but a ſhort time in bearing, ſeveral ſowings are requiſite each ſeaſon, to continue the ſucceſſion for the table all ſummer; each ſowing to remain where ſowed, chuſing a warm border, &c. for the earlieſt crops, and for the ſucceeding ones, any of the common open quarters are the moſt eligible, in a free expoſure, diſtant from ſhade of trees, &c. and open to the free air and ſun; fixing on the drieſt warm ſoil for the forwarder crops, any common ſoil for the main crops, and the moiſteſt parts for the late crops.

The general ſeaſon for ſowing is any time in open weather, from October until May or June; but remarking, that during the above period ſeveral different ſowings are neceſſary, in order to keep up a conſtant ſucceſſion of young Peas for gathering ſeveral months in ſummer, i. e. from May until September; for thoſe ſown in October or November, if they ſurvive the winter, come into bearing in May and June, and by repeated ſowings at a month, three weeks, and a fortnight's interval till May, as we before remarked, they will furniſh a conſtant ſupply of Peas all the ſummer; and thoſe ſowed late in May and in June often continue a moderate ſupply in autumn till the end of September, and ſometimes a few in October. With regard, however, to the earlieſt ſowings, from October till the beginning of January, they are liable to accidents from the ſeverity of the weather, and if they all ſtand the winter, thoſe ſowed in October will ſcarcely be a fortnight earlier

in bearing than thoſe ſowed ſix weeks or two months after: it is nevertheleſs proper to begin early, and repeat the ſowings at the intervals before mentioned, that there may be a ſufficiency for ſubſtitutes in caſe of accidents; and alſo if they all ſurvive, that there may be a regular ſucceſſion of crops coming into bearing, to afford a daily gathering through the whole ſeaſon.

But, in order to have green Peas as early as poſſible, recourſe is had to the aſſiſtance of hot-beds, by the aid of which young Peas are obtained in March and April, and continued till the coming in of the natural ground crops in May or June.

We, however, will firſt proceed with the culture of the ſeveral principal crops in the natural way; then by hot-beds.

*Hotſpur Kinds for the early and firſt general Crops.*—In October, November, or December, as may be convenient, begin to ſow the earlieſt crops; though in warm gardens it is always adviſeable to ſow a few in the two former months; but in open grounds November and December is time enough to begin, chuſing the earlieſt Charlton or Golden Hotſpurs; and for their reception prepare a warm ſouth border, or ſome other dry ſheltered ſunny ſituation; and in a dry day draw drills by line, ranging ſouth and north, to enjoy the greater advantage of the ſun's influence, making the drills an inch and a half deep, and two feet and a half at leaſt aſunder; but if deſigned to allow them ſticks, three feet and a half will be the more eligible diſtance, as we before obſerved: then having the ſeed, or Peas, ſcatter them evenly along the middle of each drill, rather ſomewhat thickiſh at theſe early ſowings in winter, becauſe they are liable to accidents from the inſults of vermin, and the inclemency of the ſeaſon; covering them in evenly with the earth, either with a rake or hoe, or with the feet; being careful that they are all equally covered the depth of the drills; and then with a rake lightly trim the ſurface ſmooth, which finiſhes the work of ſowing. The ſeeds will begin to germinate in a fortnight, if mild weather, and will come up in three weeks or a month, ſeldom in leſs time at this ſeaſon; when the plants are to be managed as hereafter directed.

Having thus performed the firſt ſowing of the Hotſpur kinds, then, agreeable to the aforementioned rules, another ſowing ſhould be performed in three weeks or a month after; but if you ſowed in October or early in November, it is adviſeable to repeat the ſowing in a fortnight or three weeks, for fear the firſt ſhould fail; and after this continue ſowing once in three weeks or a month all winter in mild weather, the ſame kinds, not forgetting towards ſpring to ſow a principal crop of the Reading Hotſpurs; obſerving as the ſeaſon advances the ſowings may be in more open expoſures, and more in quantity than the early ſowings; and as the ſpring draws on, the ſowings ſhould be repeated oftener; as for inſtance, from about Chriſtmas till the beginning of March it ſhould be once in three weeks at leaſt; and from that time till May, once a fortnight will be neceſſary, though as the warm weather increaſes, a ſmall ſowing may be neceſſary every ten or twelve days. It muſt be obſerved, however, theſe frequent ſowings are principally to be underſtood for practice in private gardens, for the ſupply of ſuch families that require a daily ſucceſſion of young Peas during the whole ſeaſon; but for large quantities in fields, where only a ſucceſſion of general crops are required juſt during the principal Pea ſeaſon, June, July, and Auguſt; three or four different ſowings from November or December until March or April may be ſufficient.

All the different ſowing will come up regularly in ſucceſſive order; but the winter and ſpring ſowings differ materially in the time they require to germinate and come up; thoſe ſowed any time in winter are ſometimes three weeks, or near a month before they come up; but thoſe ſowed towards ſpring come up ſooner; and March and April ſowings will often riſe in leſs than a fortnight, eſpecially thoſe ſowed in April, and ſometimes ſowings performed in April and May will will come up in a week.

As to the culture of all theſe ſorts after they come up, it is very eaſy; obſerve as follows.

According as the plants of each ſowing come up, and have advanced two or three inches high, it is proper to begin the firſt culture by drawing a little earth with a hoe up to their ſhanks on each ſide of every row, to ſtrengthen them and forward their growth; at the ſame time cutting down all weeds: repeating the earthing, &c. once or twice at about a fortnight's interval, or a little more or leſs as occaſion may require; and when the plants are ſix or eight inches high, thoſe you deſign for ſticks ſhould then be ſticked.

But as the earlieſt crops that come up in November or December, are often in danger from the ſeverity of froſts; it is, therefore, proper, when the plants are about an inch, or an inch and a half high, to draw a little fine earth lightly up to their ſhanks, in a dry day: likewiſe it will be of much advantage to give occaſional protection to the earlieſt plants in ſevere weather, by covering them lightly with long, light, dry litter, of the ſtraw kind, or with mats; which in private gardens, where there is a moderate quantity, in warm borders, might be eaſily effected: this need only be practiſed in very rigorous froſts, but be ſure to uncover them every fine ſunny day, and the moment the froſt breaks diſcontinue the covering entirely; for they muſt by no means be kept too cloſe, which would draw them up weak and tender; but by a judicious protection, the crop is often preſerved in tolerable condition, and forwarded much ſooner to bearing than if it had been left entirely expoſed; obſerve alſo, that according as the the plants advance, repeat the earthing up their ſhanks a little at a time in dry mild weather, at leaſt two or three times till ſpring; it will protect them the better from froſt, ſtrengthen, and forward their growth: this is all they require during winter. In ſpring hoe up all weeds, and give them a final earthing, an inch or two up their ſhanks; and then, if intended to allow them ſticks, let it be done when the plants are ſix or eight inches high: having branchy ſticks of three or four feet length, ſtick a range of them along by each row of Peas, on the ſoutherly ſide of each row; the plants will readily catch hold, and gradually aſcend by their tendrils, bloſſoming as they advance; if, when in bloſſom, the weather ſhould prove dry, ſome good waterings in a morning will be beneficial culture; and when the bloſſoming plants are advanced ſome conſiderable height, if they are then topped, it will promote the pods ſetting more expeditiouſly, and arriving ſooner to perfection.

As to the other ſucceeding crops of the Hotſpur kinds, all they require is hoeing up the earth to their ſhanks, and cut up all weeds when they appear; and thoſe deſigned for ſticks, ſhould always be ſticked as ſoon as they are half a foot high, or a little more, before the plants begin to fall down to one ſide; providing ſticks for this purpoſe, about four or five feet long, and place one range to each row of Peas; placing them principally on the ſouth ſide of the rows, becauſe the plants naturally incline towards the ſun, and thereby more readily attach themſelves to the ſticks.

*Larger Kinds for the later general Crops.*—With reſpect to the larger kinds, ſuch as the Marrowfats, Spaniſh Morattos, &c. we may begin ſowing in January, if they are in great requeſt, the dwarf Marrowfats firſt; though February, March, and April is the moſt eligible ſeaſon for ſowing the general crops of all the large kinds; obſerving to chuſe a free expoſure in the moſt open quarters, there drawing drills by line, about an inch and a half or two inches deep, and not leſs than a yard aſunder; but if to be ſticked, four feet, and for the largeſt ſorts four feet and a half: ſow the ſeed thinly along the middle of each drill, and draw the earth evenly over them with the rake, hoe, or feet, covering them equally the depth of the drills, and rake the ſurface ſmooth. Repeat the ſowings once a fortnight or three weeks; though as the ſpring and the warm ſeaſon advance, once a fortnight will be proper, eſpecially from the beginning of April until the end of May; or in May and June may ſow a few once in ten or twelve days: late ſowings, however, performed from the middle of May till about the middle of June are ſeldom very fruitful, being often attacked with the mildew; but in family gardens it is proper to endeavour to have ſome as long in the ſeaſon as poſſible.

When the different crops of theſe are come up about three inches high, hoe up earth to them on each ſide of the row; and cut down all weeds, repeating the hoeing occaſionally according as the growth of weeds ſhall require; and when they are half a foot, or eight or ten inches high, thoſe you intend ſticking ſhould have the ſticks placed to them: obſerving, theſe large ſorts require ſticks ſix or ſeven feet high at leaſt, placing them on the ſunny ſide of the rows, as we ſaid for the Hotſpurs.

*Late Crops.*—Any of the ſorts, either Hotſpurs or larger kinds, that are moſt approved of, may be continued ſowing all May and until towards the middle of June, chuſing the ſtrongeſt moiſt ground; but I would, however, obſerve, that for theſe late crops, the larger kinds of peas are the moſt to be depended on; and for the lateſt crops of all, ſow chiefly the Rouncivals, they being rather the hardieſt to ſtruggle with the ſummer's drought; but Peas of any ſort that are ſowed after May is out, are rarely very ſucceſsful, they being generally attacked by the mildew, &c. it is, however, worth the trial, and if they

they bear but a few after the general ſeaſon, they will be a rarity; and in ſowing the later crops in May and June, if the weather ſhould prove dry and hot, it will be of importance to ſoak the Peas in ſoft water ſix or eight hours previous to ſowing, otherwiſe water the drills well; either of which will promote their riſing very expeditiouſly and more regularly together.

*Other general Remarks relative to all the Sorts.*

I have obſerved in performing the different ſowings of Peas, with reſpect to the intervals of time between the ſowings, it was a good rule, that as ſoon as one crop appeared fairly above ground, to ſow another to ſucceed it, whether in winter, ſpring, or ſummer; ſo continuing it to every crop, which will be found an infallible rule in ſowing, ſo as to have a regular ſucceſſion of crops following one another in bearing.

If a crop of Marrowfats, &c. and another of Hotſpurs are ſowed on the ſame day, the Hotſpurs will come into bearing a fortnight the ſooneſt, and the Marrowfats will arrive to a bearing ſtate about the time the others are going out, juſt in due time to ſucceed them: mark this, therefore, when intended to have theſe ſorts form a regular ſucceſſion to each other.

Such crops of Peas that you deſign to indulge with ſticks for ſupport, ſhould always have the ſticks placed when the plants are from about ſix to eight or ten inches high, whilſt they maintain their upright poſition of growth; and as at that height they begin to emit tendrils, they will very readily attach themſelves to the ſticks.

With regard to the ſticks proper for ſticking Peas, it is incumbent on us to procure ſuch that are branchy, or furniſhed with many ſide ſhoots, and of proper length, according to the ſorts of Peas they are intended to ſupport; they may be either the loppings of trees, or any buſhy underwood that is well feathered with ſmall lateral branches the whole length, for the plants to run upon; obſerving, that if for the Hotſpur Peas, to prepare them about four or five feet long; but for the large kinds, ſix or ſeven feet length will be requiſite, or more for the largeſt Marrowfats, &c. ſtriming them all ſomewhat fan-faſhion, ſo as the branches may ſpread only two ways, to range the way of the rows of the plants, and ſharpen the lower end of each: being thus prepared, place one row of ſticks to each line of Peas; which will be ſufficient, eſpecially if placed on the moſt ſunny ſide of the rows, becauſe the ſun's influence will incline all the plants that way, and thereby more readily encounter with the ſticks; placing the ſticks about a foot aſunder, or a little more or leſs, ſo as the branches of the different ſticks meet; and as ſoon as one row is ſticked, then with a hoe draw a little earth up to the oppoſite ſide of the rows of plants, to lay them towards the ſticks: when the whole is ſticked, if the tops of the ſticks appear very ſtraggling and unequal, you may juſt run over them with the garden ſheers to give a little air of regularity.

In gathering the product of Peas, both hands ought always to be employed, one to hold the peduncle, or ſootſtalk of the fruit, while the other pull the pods, otherwiſe the ſtem or main ſtalk of the plant, being ſlender, fragile, and weak, would be very liable to be broken.

The gatherings ſhould always be regular; according as the pods fill, never let them ſtand to grow old, but gather them whilſt young and green, as they are then in greateſt perfection for eating, and the plants will continue longer in bearing.

A crop of Peas continues only about a fortnight in full bearing; during which time they will furniſh a plentiful gathering of pods in their ultimate perfection; though in moiſt ſhowery weather they ſometimes continue ſhooting and flowering three or four weeks, but the produce after the firſt fortnight, is generally inferior both in quantity and quality; hence the neceſſity of repeated ſowings every three or four weeks.

As ſoon as any crops of Peas that have been ſticked are paſt bearing, take up all the ſticks, and tie them in bundles, and ſet them upright in any dry corner; they will ſerve another year.

*Early Culture by Hot-beds.*

By Hot-beds—Where it is required to have a few green Peas as early in the year as poſſible, recourſe is had to the aſſiſtance of hot-beds, as we before ſaid, and the proper ſort of Peas for this purpoſe is the dwarf kind, which by this aid may be brought to bearing in March and April, and the following is the method.

It muſt be previouſly obſerved, that it is rather moſt eligible to raiſe the plants firſt in the natural ground, in October or November, till two or three inches high, then tranſplant them into the hot-bed, in January or beginning of February; for by this practice the luxurian-

luxuriant growth of the plants is ſomewhat checked by removal, ſo as they will be more eaſily contained within due compaſs, and thereby will bloſſom and bear ſooner and more abundantly.

In October or November, therefore, prepare a warm, dry, ſouth border; then having ſome true dwarf Peas, ſow them in drills about a foot aſunder, in the manner as for the common crops, when the plants are come up, and advanced a little in growth, then in a dry day draw ſome fine earth up to their ſtems, which you will repeat as you ſhall ſee occaſion during the winter; obſerving if the froſt ſhould ſet in ſevere, you muſt afford them protection, either of frames, or coverings of mats, or elſe ſome long ſtrawey litter, being careful, however, to expoſe them every favourable day, for they muſt not be drawn up weak and tender.

Then in mild weather, towards the middle or latter end of January, or beginning of February at fartheſt, prepare a hot-bed for one or more of the largeſt three-light frames and glaſſes; the hot-bed may be either be of dung or tan; the latter where it can be obtained eaſily at a moderate expence, is conſiderably the beſt hot-bed for this purpoſe: however, of either of theſe materials make the hot-bed two feet and a half or a yard thick, and cover it with frames and lights, and when arrived to a moderate temperature of heat, put on the earth for the reception of the plants, ſee HOT-BEDS. Chuſe any light good dry earth, and lay it eight or ten inches thick all over the bed; then in a dry mild day, take up the plants out of the border with a trowel, raiſing them with their roots as entire as poſſible, with what earth will readily hang about; and drawing drills in the earth of the hot-bed, from the back to the front of the frame, a foot and a half aſunder, and one or two inches deep, put in the plants in the drills, not more than an inch apart, covering in the earth cloſe to their roots and ſtems, and give a very light watering, juſt to ſettle the earth; which done, put on the lights; being careful to tilt them occaſionally at one end to give vent to the ſteam, &c. obſerving at firſt planting, if in ſunny days the plants ſhould flag, give a moderate ſhade in the middle of the day till the plants have taken root.

After this you will admit freſh air to the plants daily in fine weather to ſtrengthen them, by tilting the lights more or leſs, according to the temperature of the bed and outward air; but keep them cloſe in cold nights, and cover alſo with mats; give occaſional moderate waterings in fine days; and as the plants advance in growth draw a little earth up to their ſtems once or twice; repeating the moderate refreſhments water frequently as the warm ſeaſon advances; which may be given more freely when the plants are in bloom: obſerving according to the advanced growth of the plants and encreaſed warmth of the weather, to give a larger ſhare of freſh air in proportion; and when they are in bloſſom, obſerve if the ſun at any time appears too violent for them through the glaſſes, it is adviſeable to give a very ſlight ſhade an hour or two in the heat of ſunny days; likewiſe when in full bloſſom and fruiting, be ſure to admit plenty of free air, even ſometimes in fine days ſhove the glaſſes entirely off; ſtill alſo continue the waterings more abundantly during the time of ſetting and growth of the pods, and indulge them with the benefit of warm ſhowers.

Thus the plants may be brought to bearing in March and April, and by a ſucceſſion of two crops, in hot-beds made at three or four weeks interval, and managed as above, you may continue a ſupply till the natural ground crops come into bearing in May.

*Hints reſpecting the Culture in Fields.*

In the field culture of Peas, where deſigned to raiſe crops in order to gather the produce green and young for the ſupply of markets, November or rather December is time enough to begin the firſt ſowings, eſpecially in open expoſed grounds; chuſing a dry light ſoil for the forward ſowings.

As to the ſorts of Peas, any of the Hotſpurs for the forward crops, as obſerved in the garden culture, and for a general crop the Reading Hotſpur is excellent; but of the large kinds, chuſe principally the Marrowfats and Spaniſh Morattos for the main crop.

The ground for their reception is prepared by proper ploughing and harrowing; drills are then to be drawn with a hoe, croſs ways the lands, or if with a drill-plough length-ways, two feet at leaſt, or two and a half aſunder for the Hotſpurs, and three for the larger ſorts; no ſticks being intended for theſe field crops; and having ſowed the ſeed, cover them in either with a hoe or rake, though this is ſometimes performed with a harrow; but the hoe or rake will cover them more evenly, and almoſt as expeditiouſly.

When

When the plants come up they muſt be kept clean from weeds, by broad-hoeing; but this is ſometimes performed in fields by horſe-hoeing for the ſake of expedition; which having hoes fixed in a ſort of plough horizontally, is drawn by a horſe between the rows, a man holding the plough-ſhafts to guide it; but as this can only cut down the weeds, a common drawing man-hoe muſt be uſed to earth up the plants; though this is often diſregarded in the field-culture, it however proves very beneficial to the crop.

*Saving Seed of all the Varieties.*

To ſave ſeed Peas of the different varieties as perfect each in its kind as poſſible, ſome of each ſort ſhould be ſuffered to ſtand entirely for that purpoſe, or rather ſow ſome of each purpoſely in different parts, and ſuffer the whole produce to remain and ripen for ſeed: this, however, in private gardens is rarely well attended to, for it is a very common practice to gather all the prime whilſt young and green for the table, and let the gleanings remain for ſeed, which, although they will grow very well, and bear in tolerable plenty, yet the produce for the generality will be more ſcanty, ſmaller, and tend to degeneracy.

Obſerving, however, that when intended to raiſe a quantity purpoſely for ſeed, they ſhould be ſowed in February in ſome open ground, in rows two or three feet aſunder, no ſticks being required, and when the plants come up, keep them clean from weeds by hoeing, and hoe the earth up to their ſtems once or twice.

When they are in bloom, examine them row and row, to ſee if there is any degenerate ſort to pull it out, or if any improved variety is diſcovered, to mark it; which is the only method to preſerve both the purity of the known ſorts, and to procure new varieties; for example, if amongſt the Hotſpurs any large ſorts appear, remove them directly; removing alſo any Hotſpurs, &c. from amongſt the large kinds, and different ſorts of each of theſe from each other; and if any new ſort diſcovers itſelf either by flowering earlier than all the reſt, or poſſeſſing ſome other ſingularity, let them be carefully marked to ſave the ſeed of them ſeparate,

According as the ſeeds of all ſorts ripen in July and Auguſt, which is diſcoverable when the pods change brown, and the ſeed becomes a little hard, let the haulm be cut or pulled up in dry weather, and expoſed in heaps in the ſun, turning them every day; and when the ſeed is become perfectly dry and hard, it may either be threſhed out directly, or ſtacked up in the dry till another opportunity; but whenever it is threſhed, keep each ſort ſeparate, and when properly cleaned, put them up alſo ſeparate, in bags or ſacks, with a label to each, expreſſing the name of the variety.

PLANTATIONS, Plantations of trees, woods, &c.

Plantations of trees, &c. greatly embelliſh and improve eſtates, as well as ornament the adjacent country; and thoſe formed into woods for timber-trees, prove not only very beneficial to the owners, but may be ſaid to be a public convenience to the country around, to have the opportunity of purchaſing wood in the neighbourhood, for the various purpoſes of buildings, fencings, making all ſorts of huſbandry implements, as carts, waggons, ploughs, &c. and for innumerable other uſes; alſo for furniſhing fuel, a very eſſential article.

In former ages this iſland abounded in natural plantations or foreſts, which ſpread themſelves over the ſurface of the country, to a very conſiderable extent, and compoſed of various ſorts of loſty trees of prodigious magnitude, all blended promiſcuouſly together, and all of ſpontaneous growth. Thoſe vaſt foreſts were never planted by any human hand, ſuch only have been employed for ages in cutting them down, for in many places there were ſuch a profuſion of uſeleſs wood, that large tracts were obliged to be cleared by degrees, in order to cultivate the ground for other purpoſes; which, together with the neceſſary demands for the timber from time to time for buildings, &c. and that owners of eſtates, reaping conſiderable advantage from the ſale of their timber, continued by by degrees, one generation after another, grubbing up their timber without meaſure; and few ever planted any in lieu of what they cut down; ſo that in many parts there is almoſt a general demolition of woodland, and many conſiderable eſtates have ſcarcely any timber of value left ſtanding, whence comes the preſent ſcarcity in many parts of the kingdom.

Every poſſeſſor of eſtates, either of large or moderate extent, will reap great pleaſure and advantage in dedicating ſome ſhare of his land

land to plantations; for in eſtates of whatſoever extent, they give grandeur and ornament to the premiſes, as well as an air of fertility and riches; and thoſe large plantations deſigned for woods, will, after the firſt eight or ten years, bring in great profit by a gradual thinning of the underwood, beſides leaving a ſufficiency of ſtandards to attain full growth: in the mean time the plantations in general will contribute exceedingly to the beauty of the eſtate; for how deligtfully it is for travellers to behold the noble plantations in groves, thickets, clumps, &c. variouſly diſpoſed in parks, and on the boundaries of ſpacious lawns, and the like places, formed of a great variety of beautiful trees and ſhrubs, and to ſee grand avenues of loſty growth, leading to or from a ſtately manſion, or ſome main road, or ſome adjacent town; and in the out-grounds to obſerve the Plantations of woodlands, &c. ranging along the ſides of hills, plains, and other grounds occaſionally; but in eſtates how fertile ſoever the ſoil, yet it appears naked and barren without a proper ſhare of Plantations; on the other hand, when eſtates are beautifully diverſified with Plantations, the whole may be ſaid to form a ſort of pleaſure-garden; eſpecially as in the homeward Plantations we may have commodious walks of gravel and ſand, both private, ſhady, and ſheltered walks, occaſionally diſpoſed in many winding turns in the ſerpentine way, bordered with hardy ſhrubs and flowers, which will afford moſt agreeable walking at almoſt any ſeaſon of the year, as in ſummer they afford a ſcreen from the vehement heat of the ſun, and at other times ſhelter from boiſterous winds, and cold piercing blaſts; there may be alſo here and there receſſes or places of retirement, leading by private turnings from the principal walks; with glades or openings of graſs-ground in the midſt of the moſt extended parts of the Plantations. See PLEASURE-GARDEN.

No land-holder, therefore, let the extent be almoſt ever ſo moderate or conſiderable, but ought to appropriate a proportionable ſhare to commodious Plantations as ſoon as poſſible, either for ornament or emolument, or both, where the extent will admit, as there is hardly any eſtate that does not afford ſoil and ſituation proper for the cultivation of all our hardy trees, &c. and in many places often furniſh ſoils improper for graſs and corn, yet adapted to the growth of many ſorts of trees, which would form good Plantations, and ſecure to the planter and his poſterity a future pleaſure and revenue of conſiderable importance.

In ſhort there is hardly any ſoil ſo barren and untractable but what will rear a growth of trees and ſhrubs of ſome ſpecies or other, both for ornament and advantage; and there is ſcarcely any kind of tree ſo bad but may be raiſed to one or other of thoſe purpoſes: any very poor ground, or ſuch that lie waſte, or at a great diſtance, cannot be better improved than in Plantations; even although a tract of land ſhould be ſo poor as to rear nothing but a crop of aſpen trees, alder, and willows, yet the profits even of theſe productions will greatly exceed what many may think.

So that there is a great number of examples to encourage, and warrant ſucceſs in Plantations, to reward not only with the pleaſure of ornamenting his lands, and that of beholding their growth, but alſo with profit ſufficient to compenſate amply for the tract of land occupied, and labour in planting.

But to many perſons, the neceſſary expence attending the making a Plantation, and knowing that they muſt wait ſeveral years before the trees have made any conſiderable progreſs, or can reap any advantage therefrom, often proves an obſtacle in attempting the proſecution of that buſineſs; but as to the expence of planting, if you raiſe the plants in your own grounds, it will not prove near ſo great as many might imagine, eſpecially as a ſmall ſpot of ſeminary or nurſery-ground will raiſe plants enough in three or four years to plant a great many acres of land, both ornamental and woodland; and by the latter, the expence of raiſing and planting them, together with the loſs of time in waiting a few years till the plants attain ſome growth, will be compenſated by the firſt fall or thinning of the underwood, in eight or ten years after planting; and the ſtools or roots remaining ſhoot up again, and afford a lopping every eight or ten years, excluſive of the due portion of ſtandards left at proper diſtances, to attain full growth for timber, as aforeſaid.

One particular precaution in making Plantations, is the judicious choice of ſuch trees as are the beſt adapted to the nature of particular ſoils, which may vary exceedingly in eſtates of great extent; however, ſuch trees

as

as we find daily growing by road-ſides, hedge-rows, and in any adjacent grounds are rough ſketches of what the land will produce.

As to the ſorts of trees and ſhrubs proper for Plantations in general, there is a vaſt variety, both of the deciduous and ever-green tribes, that will proſper in the open ground in any common ſoil. See DECIDUOUS and EVER-GREEN TREES, &c.

It is of importance, in making any conſiderable Plantation, to chuſe principally young plants, of from about two or three to five or ten feet ſtature, which always prove more ſucceſsful than older trees; for although ſome perſons being in haſte to have Plantations as forward as poſſible in a few years, tranſplant tall trees, perhaps twelve or fifteen feet high or more, particularly for ornamental Plantations; yet younger growth always take root ſooner, and more firmly eſtabliſh themſelves, ſo as to form conſiderably the fineſt Plantations at laſt, and be of longeſt duration; for although large trees of from ten to twenty feet height, eſpecially of the deciduous kind, may with care be tranſplanted, ſo as to grow and probably thrive tolerably for ſome years, yet trees more than twelve or fifteen feet high often fail, by not rooting firmly like young plants, and after ſome years ſtanding, have hardly made any ſhoots, and at laſt gradually dwindle and periſh; therefore large trees ſhould never be employed for Plantations only on particular occaſions, where a few may be neceſſary to form an immediate ſhade or blind, &c. in ſome particular place; but for general work, be perſuaded to employ chiefly young plants, either of your own raiſing, or purchaſed from the nurſeries. And for timber Plantations in particular, I would chuſe ſuch plants as are only from about two or three, to five or ſix feet in height. See PLANTING.

All the different ſorts of trees and ſhrubs proper both for ornamental and timber Plantations, may be had at all the public nurſeries moderately reaſonable; though perſons accommodated with ſcope of ground, may eaſily raiſe all the ſorts for his own private uſe, by the methods directed under the reſpective genera: a ſmall nurſery will raiſe trees and ſhrubs enough to plant many acres of land. See NURSERY.

Obſerve, that where Plantations are intended principally for ornament, as great a variety as poſſible of the different ſorts of hardy trees and ſhrubs ſhould be employed, to afford the greater ſource of entertainment; and ſhould conſiſt both of lofty and middling trees, down to the humbleſt ſhrub. See DECIDUOUS and EVER-GREEN TREES. Diſpoſing the deciduous and ever-green plants principally in ſeparate compartments; ſometimes arranging the tree-kinds by themſelves, ſome in running irregular Plantations, towards the boundaries of ſpacious lawns, parks, paddocks, &c. others in avenues, groves, thickets, and clumps, as aforeſaid, variouſly diſpoſed in different parts; and ſometimes arranging the trees and ſhrubs together, in forming ſhrubberies, wilderneſs, ſhady walks, and wood-works; placing the taller growth backward, and the lower in front; bordering the whole with the moſt beautiful flowering ſhrubs, and ſhowy ever-greens, eſpecially next the principal walks and lawns; obſerving to vary the form of all the ſeveral compartments, ſometimes by bold ſweeps and curves outward and inward, of different dimenſions, other parts in long eaſy bends, irregular projections and breaks, ſo as to diverſify the ſcene in imitation of a natural Plantations. Allow all the ſorts proper diſtances, which may be from five or ten to fifteen or twenty feet, for example, the tall trees deſigned for continued Plantations may be from ten to fifteen or twenty feet, varying the diſtance in different parts, according as light and ſhade, &c. may be proper; and thoſe in groves, may, if open groves, be fifteen or twenty feet diſtance, and cloſe groves ten or twelve; for thickets, five or ſix feet, or cloſer in particular places where a very dark ſhade, or thick coverture of wood is required; and in clumps of trees, may allow from five or ten to twenty feet between the trees in each clump, varying the diſtance occaſionally, as alſo the ſorts and numbers of trees in each, from two or three to ten or more: likewiſe the form of the clumps; ſome may be triangular, others quadrangular, pentangular, &c. and ſome in curves, others in ſtraight lines, to cauſe the greater variety. And as to the ſhrubbery clumps, and wilderneſs compartments, where the trees ſhrubs are employed promiſcuouſly together, they may be planted from five to ten feet diſtance; the taller growth being placed backward eight or ten feet aſunder, placing the lower plants gradually forward according to their gradation of ſtature, to the loweſt in front, as above obſerved, at four or five feet diſtance: and if the trees and ſhrubs of the Plantations in general are diſpoſed ſomewhat in the quincunx way, they will appear to the greater advantage.

But when deſigned to form large Plantations into woods, &c. compoſed principally of

foreſt and timber-trees for profit, particular ſorts muſt be choſen, conſiſting both of deciduous and ever-green trees. Of the deciduous kinds chuſing the oak, elm, aſh, beech, cheſnut, hornbeam, birch, alder, maple, ſycamore, plane-tree, poplar, lime-tree, walnut-tree, wild cherry-tree, mountain-aſh, larch-tree, willow-tree, hazel-tree, &c. and of the ever-greens, the pine-trees, firs, cedar of Lebanon, holly-tree, bay-tree, laurel-tree, yew-tree, ever-green oak, box-tree, and ſome others. See FOREST-TREES. The particular deſcription and culture of all of which ſorts, deciduous and ever-greens, are exhibited in their proper genera. They are all hardy, and will grow in almoſt any common ſoil, rich or poor, and moſtly alſo in dry or moiſt ground, high or low; allotting, however, particular ſorts to very low marſhy ſoils, ſuch as the willow, ſallow and oſier, poplar, alder, and other aquatics, which will proſper in places that are in a manner covered with water, and are the moſt proper ſorts for the embelliſhing and improvement of ſuch grounds: all the other ſorts will ſucceed in any other more upland places out of water; obſerving, with reſpect to diſpoſition, the deciduous and ever-greens ſhould generally be ſeparate, as obſerved for the ornamental Plantations. But the trees of the ſame tribe may ſometimes be intermixed, and ſometimes different ſorts in ſeparate diviſions or quarters, as oaks in one, elms in another, &c. remarking likewiſe in timber Plantations, that all the trees ſhould be planted pretty cloſe together, i. e. not more than three or four feet diſtance, in order that they may mutually draw each other up tall, more expeditiouſly, and to allow for a gradual thinning, as hereafter directed.

In forming woods, however, or Plantations of timber-trees, the following hints in reſpect to planting them are proper to be obſerved.

Let it therefore be remarked, that there are two methods practiſed in forming Plantations of woodlands; one is by raiſing the trees from ſeed at once on the ground where the Plantation is intended to be, eſpecially of the deciduous kind, and is effected by ſowing the ſeed in drills, a yard aſunder, and the plants always to remain where raiſed, thinning them gradually: the other method is by previouſly raiſing the plants in a nurſery, till two or three feet high, then tranſplanting them into places allotted them, in rows the above diſtance, to allow alſo for gradually thinning.

Either of theſe two methods may be practiſed, as ſhall ſeem moſt convenient to the owner; but the former, i. e. raiſing the plants where they are to remain, that although it may be more expeditious, and that at once to get rid of the trouble of tranſplantation, yet they will require greater attendance for a few years, till the plants have ſhot up out of the way of weeds; but on the other hand, the trees always remaining where raiſed, not diſturbed by removal, they probably may make the greater progreſs. The latter method, however, of raiſing the trees firſt in a nurſery, is rather the moſt commonly practiſed, as being thought the leaſt troubleſome and expenſive, with regard to the attendance at firſt of the young growth. However, every one is at liberty to make the experiment as it ſuits his convenience.

The preparation of the ground for the final reception of the ſeed or plants of theſe Plantations, is by deep ploughing and harrowing, upon ſuch ground where the plough can be employed; where this, however, or any other tillage is not practicable, we muſt uſe only young plants from the nurſery, making holes, &c. at proper diſtances, for the reception of each plant: where, however, the ground can be tilled, it will prove very advantageous, performing it previouſly a year at leaſt before; ſowing it with a crop of turneps, or the like: when theſe come off, well plough and harrow the ground again, for the reception either of the ſeed or plants the enſuing ſeaſon.

The moſt proper ſeaſon to perform this planting, either by ſeed or plants, is any time in dry mild weather, from October or November till February, though November and February are rather the moſt eligible for moſt kinds of hardy tree ſeeds: however, where large tracts are to be planted, both methods muſt be purſued all winter, at every favourable opportunity.

If ſeed is intended, you muſt be well provided with ſeeds of the ſeveral deciduous trees in particular, which may be obtained at all the nurſeries and eminent ſeed-ſhops; then, for its reception, draw furrows or drills about two or three inches deep, and three or four feet aſunder, ſcatter the ſeed along the middle of the drills, and cover the earth evenly over them, the depth of the drills or furrows, and place ſcare-crows and traps to guard againſt

againſt the inſults of birds and vermin.

But if deſigned to form the Plantation with young plants, previouſly raiſed in beds in the nurſery by the common method, let the following practice be obſerved: chuſe always young plants, only from two to three or five or ſix feet high; and if very large Plantations are intended, you may, to ſave time and trouble, take the plants immediately from the ſeed-bed, when one or two feet high, without giving them any previous tranſplantation in the nurſery; though where the Plantations are but moderate, it is moſt eligible to plant them out previouſly in nurſery-rows, to have two or three years growth: but for remarkable large Plantations, this would be a very great trouble and expence. Being, however, furniſhed with young plants, they are to be planted in rows, three or four feet aſunder, as directed for the ſeed, and one or two feet apart in the lines: they may be planted either by opening ſmall apertures or holes with the ſpade for each plant; or, if very ſmall plants, it is ſometimes performed by making only a ſlit or crevice with the ſpade for each plant; and ſome open ſmall trenches the whole length, then one inſerts the plants whilſt another trims in the earth about their roots: ſome again, in very large tracts, where the ſituation admits of good ploughing and harrowing to divide and break the earth into ſmall particles, open furrows with a plough, two perſons being employed in depoſiting the trees in the furrow, whilſt the plough following immediately with another furrow, covers the roots of the plants with the earth thereof. See PLANTING.

The ground where the above Plantations are made ſhould be previouſly fenced all round with a deep ditch, &c. to guard againſt the encroachments of cattle.

Whilſt theſe plantations are young, they muſt have ſome attendance to deſtroy weeds, which may be expeditiouſly executed by hoeing between the rows in dry weather, particularly by horſe-hoeing; and this care will be needful for two or three years, eſpecially the ſeedling Plantations, till the trees are advanced out of the reach of weeds; after which no farther trouble will be required until the trees are ready for the firſt fall or thinning, for poles, faggots, &c.

In eight or ten years growth, they will be of a proper ſize to begin the firſt fall by a moderate thinning, which will ſerve for poles and faggot-wood, to pay towards the expence of planting, &c. but begin lopping only part of the Plantation the firſt year; thinning out the weakeſt and moſt unpromiſing growth firſt; leaving a ſufficiency of the moſt vigorous plants pretty cloſe, to grow up for larger purpoſes; the year following begin thinning another part, and ſo continue an annual thinning-fall till got through the whole plantation; cutting each fall down near the ground, leaving the ſtools to ſhoot out again, eſpecially of the deciduous kinds, and by that time you have made the laſt fall, the firſt will have ſhot up, and ready to be cut again; ſo the returns of fallings may be contrived to be every ſix, ſeven, eight, or ten years, or more, according to the uſes the poles or wood are wanted for; and if larger poles, &c. are wanted, the fall may be only once in fourteen, eighteen, or twenty years, ſtill, at every fall, being careful always to leave enough of the moſt thriving plants for final ſtandards; leaving them pretty cloſe at firſt, that they may mutually draw each other up in height; but may be thinned every ſucceeding fall as they encreaſe in bulk and meet, ſo as to leave a ſufficient quantity of the principal trees at proper diſtances to grow up to timber, which in their turn, as they become fit for the purpoſes intended, may alſo be felled according as there may be a demand for them to the moſt advantage; having young ones from the ſtools coming up in proper ſucceſſion as ſubſtitutes, ſo as the ground may be always occupied.

PLANTING. Planting is the art of inſerting plants, ſeeds, and roots, in the earth for the purpoſe of vegetation.

There are various methods of Planting in practice for different ſorts of plants, ſeeds, and roots; ſuch as hole Planting—trench Planting—trenching-in Planting—ſlit or crevice Planting—holeing-in Planting—drill Planting—bedding-in Planting—furrow Planting—dibble Planting—trowel Planting—Planting with balls of earth about the root—Planting in pots, &c. all of which methods of Planting are occaſionally uſed by different practitioners in the ſeveral branches of gardening, according as the ſeveral methods ſhall ſeem moſt eligible for different or particular ſorts of plants. Obſerving that although moſt of the different operations are hinted in many different parts of this work in the culture of the various ſpecies of each genus, we nevertheleſs judge it expedient under this head, to exhibit ſome general directions of the manner each method is performed; together with

ſome hints of the kinds of plants, &c. that are commonly planted by the different methods, which may prove uſeful to young practitioners in performing the mechanical operations of Planting.

1. *Hole Planting.*—This is the principal method practiſed in the final Planting of all ſorts of trees and ſhrubs in the full ground, by opening with a ſpade round holes in the ground, at certain diſtances, one for the reception of each plant. Each hole ſhould be digged capacious enough to admit all the roots of the tree or ſhrub freely every way to their full ſpread, without touching the ſides of the hole, and about one ſpade deep, or a little more or leſs, or according to the ſize of the roots, ſo as, when planted, the uppermoſt ones may be only about three inches below the common ſurface, or about as low as they were before in the ground, which is diſcoverable by examining the bottom of the ſtem of the tree; though in very humid ſoils, where the water is apt to ſtand, the holes ſhould rather be ſhallow, ſo as the uppermoſt roots may ſtand full as high as the general level, or higher if it ſhall ſeem neceſſary, raiſing the ground about them, eſpecially in winter Planting: let the holes, however, be of a proper width and depth, according to the above rules, looſening the bottom well; and if too deep, it is eaſily remedied in the time of Planting, by ſhaking up the tree as you ſhall ſee occaſion; obſerving in digging out each hole, to lay the earth in a heap cloſe to the edge, in order to be ready to fill in again: the holes being ready, then, having trimmed the roots, &c. of the trees, as hereafter directed, place one tree in the middle of the hole, making all its roots ſpread equally around; a perſon holding the plant erect by the ſtem, whilſt another with his ſpade caſts in the earth about the roots, taking particular care to break all large clods, and trim in ſome of the fineſt mould firſt all round about the roots in general, ſhaking the tree occaſionally, to cauſe the fine ſoil to fall in cloſe among all the ſmall roots and fibres; at the ſame time if the tree ſtands too deep, ſhake it up gently to the proper height, and having filled in the earth to the top of the hole, tread it gently all round, firſt round the outſide to ſettle the earth cloſe to the extreme roots, continuing the treading gradually towards the ſtem, to which tread the mould moderately firm, but no where too hard, only juſt to ſettle the earth, and ſteady the plant in an upright poſition: then pare in all the remaining earth evenly round the tree, to the width of the hole, raiſing it ſomewhat above the general level of the ground, to allow for ſettling, giving it alſo a gentle tread, and finiſh it off a little hollow at top, baſon-like, the better to receive and retain the moiſture from rains, and occaſional waterings in ſpring and ſummer, particularly to the choicer kinds of trees and ſhrubs.

After performing this Planting, if in winter, or late in ſpring, it may be of advantage to the choicer kinds of trees and ſhrubs to mulch them, i. e. to lay ſome long mulch at top of all the earth, both to keep out the winter's froſt, and prevent the drying winds and drought of ſpring and ſummer from penetrating to the roots before the trees are well rooted in their new quarters; ſee MULCH. But ſome inſtead of mulch, uſe graſs turfs, turned topſy-turvy, eſpecially when planting upon any graſs ground, or any out-plantations where turfs of graſs can be obtained; or in orchards, where the ground is graſs; in which caſe it may be proper to bank ſome turfs round the ſides and top of each hole, particularly for large trees, which will ſteady them more effectually, as well as preſerve the moiſture, if much dry weather ſhould happen the ſucceeding ſummer.

The above work, however, of mulching or turfing new-planted trees, is not abſolutely neceſſary to our common hardy kinds of fruit-trees, foreſt-trees, and ſhrubs; though it may prove beneficial to all ſorts, but more particularly to the more tender kinds of wall fruit-trees, and more delicate ſorts of flowering-ſhrubs, choice ever-greens, and ſome kinds of herbaceous perennials.

2. *Trench Planting.*——This method is ſometimes practiſed in the nurſery-way, in putting out ſeedling and other ſmall trees and ſhrubs in rows; is alſo uſed for Planting box edgings; ſometimes likewiſe for Planting ſmall hedge-ſets, &c. and always in Planting *Aſparagus*, and is performed by opening a long narrow trench with a ſpade, making one ſide upright, ſo place the plants againſt the upright ſide, and turn the earth in upon their roots.

If for young ſeedlings, or other ſmall trees and ſhrubs, &c. the ground is previouſly trenched or digged; a line is then ſet, and with a ſpade held with its back towards the line, cut out a narrow trench, ſix or eight inches deep, turning the earth from the line, making the line-ſide nearly perpendicular; the

plants

plants are then inſerted in the trench at ſmall diſtances, cloſe to the upright ſide, covering in the earth about the roots as you proceed in planting them; and having planted one row, tread the earth evenly all the way along, to ſettle it cloſe, and fix the plants ſteady; and ſo proceed row and row.

But in planting larger trees in the nurſery way by *Trench Planting*, a more capacious trench will be requiſite: ſometimes a trench one or two ſpades wide, with proportionable depth, according as the roots of the trees ſhall require; ſo having opened it all the way along the intended row, proceed to place the trees along the middle of the trench, filling in ſome earth to each tree as you place it, one perſon holding it erect whilſt another throws in the earth; and having placed one row, trim in all the remaining earth evenly, then tread it cloſely all the way to fix the plants ſteady and perfectly upright.

3. *Trenching-in Planting.*]——This is alſo ſometimes practiſed in light pliable-working ground, for Planting young trees in the nurſery-way, and ſometimes in Planting hedge-ſets, &c. and is performed by digging along by a line, about one ſpade wide, and Planting as you go on. The method is this, a line is ſet, then having the plants ready, and with your ſpade beginning at one end, and ſtanding ſide-ways to the line, throw out a ſpit of earth, which forming a ſmall aperture, another perſon being ready with the plants, he directly depoſits one in the opening, whilſt the digger proceeds with the digging one ſpade wide, covers the roots of the plants with the earth of the next ſpit; and another aperture being thereby alſo formed, place therein another plant, the digger ſtill proceeding, covers its roots, as before, with the next ſpit of earth; and ſo on to the end of the row, placing them at about a foot, or fifteen or eighteen inches aſunder, according to the ſize of the plants; obſerving, when Planting larger trees with more ſpreading roots, by this method, that inſtead of digging the trench only one ſpade wide, two may probably be requiſite for the proper reception of the roots likewiſe in forming the opening for each plant, make it capacious enough to receive the roots freely, digging the earth over them as above. After having planted one row, either ſmall or large plants, tread the earth evenly along to ſettle it to the roots, and ſteady the plants all equally upright.

Another method of *Trenching-in Planting* is ſometimes uſed for Planting ſome ſorts of roots, ſuch as horſe-radiſh ſets, potatoes, &c. performed by common trenching, placing a row of ſets in each trench. The horſe-radiſh ſhould be placed in the bottom of the open trench, at fifteen or eighteen inches depth, turning the earth of the next over them; and the potatoe-ſets place about ſix inches deep, and cover them alſo with the earth of the next trench. See COCHLEARIA *Armoracia*, and SOLANUM *Tumeroſum*.

4. *Slit Planting.*]—This method is performed by making ſlits or crevices with a ſpade in the ground, at particular diſtances for the reception of ſmall trees and ſhrubplants. A ſlit being made for each plant, which are inſerted as you go on; and is practiſed ſometimes in the nurſery-way, &c. in putting out rows of ſmall plants, ſuckers, &c. at from about a foot to eighteen inches or two feet high, and that have but ſmall roots: it is alſo ſometimes practiſed for final Planting in out-grounds, where very large tracts of foreſt-trees are intended, and that they are to be planted out at the above ſizes, and by the moſt expeditious and cheapeſt method of Planting; the following is the method.

A line is ſet, or a mark made accordingly; then having a quantity of plants ready, for they muſt be planted as you proceed in making the ſlits, a man therefore having a good clean ſpade, he ſtrikes it into the ground with its back cloſe to the line or mark, forms a crevice, taking it out again directly, ſo as to leave the ſlit open, gives another ſtroke at right angles with the firſt, then the perſon with the plants inſerts one immediately into the ſecond-made crevice, bringing it up cloſe to the firſt, and directly preſs the earth cloſe to the plant with the foot; proceed in the ſame manner to inſert another plant; and ſo on till all is finiſhed, which is a very expeditious way of putting out ſmall plants, for any conſiderable plantation. See PLANTATIONS.

A man and a boy by this method will plant ten or fifteen hundred, or more in a day.

5. *Holeing-in Planting.*]—This is ſometimes uſed in the nurſery-way in light looſe ground; alſo ſometimes in Planting potatoes, &c. in pliable ſoils.

The ground being previouſly digged or trenched, and a line placed, they proceed thus:

thus: a perſon with his ſpade takes out a ſmall ſpit of earth, to form a little aperture, in which another perſon directly depoſits a plant, &c. the digger at the ſame time taking another ſpit at a little diſtance, turns the earth thereof into the firſt hole over the roots; placing directly another plant in this ſecond opening, the digger covers it with the earth of a third, and ſo on to the end of the row.

6. *Drill Planting.*]——This is by drawing drills with an hoe from two to four or five inches deep, for the reception of ſeeds and roots, and is a commodious method of Planting many ſorts of large ſeeds, ſuch as walnuts, cheſnuts, and the like; ſometimes alſo broad beans, but always for kidney-beans, and peas: likewiſe for Planting many ſorts of bulbous roots, when to be depoſited in beds by themſelves.

The drills for all of which purpoſes ſhould be drawn with a hoe, two or three inches deep, ſee HOE; though for large kinds of bulbous roots, four or five inches depth will be requiſite, covering-in the ſeeds and roots with the earth, always the depth of the drills.

7. *Bedding-in Planting.*]—This is frequently practiſed for Planting the choicer kinds of flowering bulbs, ſuch as *Hyacinths*, &c. alſo for larger ſeeds of trees, as acorns, large nuts, and other larger kinds of ſeeds, ſtones, and kernels, and is performed by drawing the earth from off the tops of the beds ſome inches depth, then planting the ſeeds or roots, and covering them over with the earth, drawn off for that purpoſe. The following is the particular method.

The ground muſt be previouſly digged or trenched, raked, and formed into beds three or four feet wide, with alleys between bed and bed; then with a rake or ſpade trim the earth evenly from off the top of the bed into the alleys, from three to four or five inches deep for bulbous roots, and for ſeeds, one or two, according to what they are, and their ſize; then, if for bulbous roots, draw lines along the ſurface of the bed, nine inches diſtance, place the roots bottom downward, along the lines, ſix or eight inches apart, but, if ſeeds, they may be ſcattered promiſcuouſly; and having thus planted one bed, then with the ſpade, let the earth that was drawn off into the alley, be ſpread evenly upon the bed again over the roots or ſeed, &c. being careful that they are covered all equally the above depth, and rake the ſurface ſmooth.

This method is much in practice among floriſts for the choicer ſorts of bulbous flowers.

The nurſerymen alſo practiſe this method in Planting many of their larger ſeeds, nuts, &c.

Another method of *Bedding-in Planting* I have ſeen practiſed in ſome parts, particularly for planting potatoes, in low wet grounds; which is by dividing the ground into beds, four feet wide, with alleys two or three feet wide between bed and bed; then digging the beds, place the potatoe-ſets in three rows rows along each bed, a foot aſunder in the row; this done, dig the alleys one ſpade, caſting the ſoil upon the over the ſets, ſo as beds to cover them about ſix inches deep: thus if the ground is very wet, the alleys will drain the moiſture from the beds, ſo as ſometimes to afford very great crops.

8. *Furrow Planting.*]—This is by drawing furrows with a plough, and depoſiting ſets or plants in the furrow, covering them in alſo with the plough; and is ſometimes practiſed for planting potatoe-ſets in fields, and has been practiſed in planting young trees for large tracts of foreſt-tree plantations, where the cheapeſt and moſt expeditious method is required; but this method can be practiſed only in light pliable ground, and is performed thus; a furrow being drawn, one or two perſons are employed in placing the ſets or plants in the furrow, whilſt the plough following immediately with another furrow, turns the earth thereof in upon the roots of the plants.

We do not, however, recommend this method of Planting potatoes for general culture; only perſons that have ſcope of ground may try the experiment.

9. *Dibble Planting.*]—This is the moſt commodious method for Planting moſt ſorts of fibrous-rooted ſeedling plants, particularly all the herbaceous tribe; alſo for planting ſlips, off-ſets, and cuttings both of herbaceous and ſhrubby kinds; likewiſe for ſome kinds of ſeeds and roots, ſuch as broad-beans, potatoe-ſets, Jeruſalem artichokes, and horſe-radiſh-ſets, with numerous ſorts of bulbous roots, &c. and is expeditiouſly performed with a dibble or ſetting-ſtick, therewith making a narrow hole in the earth for each plant, inſerting them in each hole, always as you go on; obſerve the following hints.

Having a dibble or ſetting-ſtick, it is uſed by thruſting it into the earth in a perpendicular deſcent, in depth as the particular plants, &c.

&c. may require; directly inſerting the plant, ſeed, or ſet, according as each hole is made, cloſing the hole immediately by a ſtroke of the dibble. So proceed dibbling the holes and Planting as you go on, at particular diſtances and depths, according to the nature of the Plants, &c. as exhibited in their reſpective genera: obſerving, in ſetting any kind of plants, ſlips, cuttings, and the like, having long ſhanks or ſtems, it is proper to make holes a proper depth, to admit them ſome conſiderable way in the ground; for example, cabbage-plants, ſavoys, &c. ſhould be planted down to their leaves; ſlips and cuttings ſhould be inſerted two parts of three, at leaſt, in the ground; being particularly careful in dibbling-in all ſorts of plants, to cloſe the holes well in every part about the roots, by ſtriking the dibble ſlantways into the ground, ſo as to ſtrike the mould firſt firmly up to the root and fibres, at the ſame time bringing it cloſe to the ſtem; for in dibble Planting, many only ſtrike the earth about the neck of the plant, and the lower part of the hole is often left hollow about the roots; but by ſtriking the dibble firſt at the root-part, you fix the plant effectually, then a ſtroke of the dibble at the top of the ground finiſhes, by cloſing up every part of the aperture. In this manner continue Planting and finiſhing each hole as you go on, perfectly cloſe that neither the ſun, air, nor penetrating winds can enter, this being of much importance; but often diſregarded, as we may often ſee the holes that are neceſſarily made in fixing the plants left open, which may be eaſily cloſed as they go on with the utmoſt facility, each hole at the inſertion of its plant, at one ſtroke of the dibble, as above ſaid.

For the ſorts of dibble, and ſome other particulars in dibble Planting, ſee DIBBLE.

10. *Trowel Planting.*]—This is performed with a garden-trowel, which being made hollow like a ſcoop, is uſeful in tranſplanting many ſorts of young fibrous-rooted plants with balls of earth about their roots, ſo as they may not feel their removal. See *Planting with Balls of earth, &c.*

The trowel is employed both in taking up the Plants, and planting them; obſerving the plants having been previouſly pricked out from the ſeed-bed or elſewhere, at certain diſtances, and having been of ſome ſtanding for their roots to have got good hold of the ground, they by aid of the trowel may be readily taken up, each with a good ball of earth about all its roots; and then with the trowel making a hole for it in the allotted place, inſert it in the hole with the whole ball of earth entire, and give a little water: thus the plants will ſcarcely feel their removal, and often continue their growth without loſs of time, as if they had not been tranſplanted at all.

11. *Planting with Balls of Earth about the Roots.*]—This is the removing a plant with a large ball of earth about its roots, ſo as the plant by having its roots firmly attached to the ſurrounding ball of earth, it ſtill, during the operation, continues its growing ſtate without receiving any or but very little check from its removal; and is often practiſed more particularly to the more delicate and choicer kinds of exotics, both trees, ſhrubs, and herbaceous plants: likewiſe when intended to remove any ſort of tree or plant out of the proper Planting ſeaſon, as very late in ſpring, or in ſummer, it is eligible to tranſplant it with a good ball of earth to preſerve it more certainly in a ſtate of growth. Obſerving, ſome trees and ſhrubs are more difficult to remove with a ball than moſt kinds of herbaceous fibrous-rooted plants, though many of the tree and ſhrub kinds, having very fibrey roots, they will alſo readily riſe with good balls.

However, in tranſplanting any of the tree and ſhrub kind by this method, if they grow in the full ground, we muſt be careful to begin to open a trench with a ſpade at ſome conſiderable diſtance round the ſtem, perhaps a foot, or two or three, according to the ſize of the tree and expanſion of the roots, digging a ſort of trench all round, a ſpade or two wide, or more if large trees, and in depth below all the roots; all the time having great care not to diſturb the ball, or maſs of earth between the ſtem and trench, but preſerve it as entire as poſſible, for if we looſen this part about the roots, the intended effect of ſtill preſerving the tree in a growing ſtate, will fail. Having, however, dug down below the roots all round, you muſt then undermine the ball on every ſide, below all the roots, till the whole ball is detached from the main ground; then remove the tree with its entire ball carefully to its deſtined place, having a capacious hole ready opened, if for the full ground, or if for pots have ſuch that are ſome inches wider than the ball to admit of a portion of freſh earth all round; in either method, however, plant the tree or ſhrub with its

its whole ball entire, and fill in the earth evenly all round it, preſſing it gently down, and give a moderate watering round the outſide to ſettle the earth cloſe to every ſide of the ball, then place a ſtake for ſupport.

But when trees or ſhrubs, with balls to their roots, are intended to be ſent to any conſiderable diſtance, they ſhould be placed in oſier baſkets, in order to preſerve the coheſion of the ball, having a baſket for each tree; the baſkets to be of an upright make, in width and depth in proportion to the ball, with two handles at top, and worked rather open at the ſides, becauſe ſometimes the baſket and all is placed in the ground, when the plant cannot be readily removed without danger of breaking the ball of earth; ſo that the ſides being a little open, the roots may have liberty to ſhoot out; moſt baſket-makers know how to make them. Having, however, the baſkets, put a little good earth in the bottom of each, then place the plant with its ball, fixing it properly in an upright poſition, obſerving likewiſe, in their carriage to the allotted places, to preſerve them in an upright poſture. In Planting them, if they cannot be readily moved out of the baſkets without diſturbing the ball of earth, plant baſket and all as aboveſaid; cut it here and there in the ſides, and throw ſome fine mould cloſe all round ſo as to join with that of the ball, and give a watering to ſettle it more effectually cloſe; the roots and fibres will readily make their way through the ſides of the baſket; beſides, the baſkets will ſoon rot, without proving any obſtruction to the growth of the plants.

But ſometimes, inſtead of baſkets, ſmaller young trees and other plants with balls, intended to be ſent to any diſtance, are placed in pots, one plant in a pot, and if they are to be placed in the full ground, turn each out of the pot with the ball entire; or if it ſeemingly will not readily quit the pot without ſeparating, break the pot, to preſerve the coheſion of the ball.

Many ſorts of herbaceous fibrous rooted plants, however, may readily be taken up with balls with very little trouble, by reaſon of their numerous fibres, to which the earth cloſely adheres in a compact lump all round the root; and with a ſpade or trowel may often be taken up with balls with the utmoſt facility, and in ſome ſorts the earth of the ball will cling ſo cloſe as to admit of being ſent to ſome diſtance without being potted; others again being leſs fibrous, require the aſſiſtance of a pot to preſerve the ball entire till arrived at its place of deſtination.

And as to trees and other plants that have generally grown in pots, the tranſplanting them with balls is very eaſy, for if they have been of ſome ſtanding in the pot, the whole earth thereof will by means of the numerous fibres, be formed into one compact lump, as it were, that it will readily come out entire and firm; or to ſuch as do not ſo eaſily quit the pot, thruſt a long blade of a knife, or ſome other thin inſtrument, down between the outſide of the ball and pot all round, it will then readily come out either in drawing by the ſtem of the plant, or, by ſtriking the edge of the pot with ſomething; or, if ſmall plants, may turn the pot mouth downward, and ſtrike the edge gently againſt any thing: obſerve, in replanting thoſe potted plants, that if the ſides of the ball of earth is much matted with the fibres of the root, it is proper to pare off the groſſeſt part, together with a little of the old earth, eſpecially if to be planted in pots again; then Planting it in a pot a ſize larger than before, filling up all round with freſh mould, and finiſh with a moderate watering. See *Planting pots*, below.

The advantage in Planting with balls, either in the full ground, or in pots, is, the root of the plant being encloſed in the ball of earth, continues all the while drawing nouriſhment, and the growth of the plant is not retarded in waiting till it has taken freſh root in its new place, which may be of advantage in many caſes, particularly all tender plants, ſome of our choiceſt ever-greens, and many kinds of herbaceous flower plants.

But Planting with balls is not recommended for general practice, for all the hardy tree and ſhrub kind it would be needleſs as well as very expenſive and troubleſome.

12. *Planting in pots.*]—This is practiſed to all tender exotics, in order for moving them to ſhelter occaſionally, ſuch as all kinds of green-houſe and hot-houſe plants; and it is likewiſe practiſed for many ſorts of hardy flowering-plants, for the convenience of moving them occaſionally to adorn any particular compartments; and for the convenience of moving ſome curious ſorts when in flower to occaſional ſhelter from the ſun's rays, and exceſſive rains, in order to preſerve their beauty and prolong the time of their bloom; ſuch as the fine auriculas, carnations, &c.

In

In Planting in pots, it is highly requiſite carefully to adapt the ſizes to the ſize and nature of the different plants intended to be potted; if ſmall plants, begin firſt with ſmall pots, one plant only to each pot, eſpecially if to remain; but according as the different plants advance in growth, ſhift them into pots one or two ſizes larger, which may be requiſite to many ſorts once a year, to others once in two or three years, according to the nature and encreaſed growth of the reſpective plants: though to ſome ſort of annuals it may be neceſſary once or twice in the courſe of a ſeaſon; all of which is generally particularized in the culture of the various ſorts. And by thus beginning firſt with ſmall pots adapted to the ſize of the plants, it is not only cheaper and more commodious for moving and ſtowing them in different parts occaſionally, till they gradually advance in growth, but by thus ſhifting them into pots a ſize larger, it admits of adding freſh earth, which proves highly beneficial to their growth.

Garden pots for the reception of plants are of ſeveral regular ſizes, from two to ſixty in a caſt, ſo are diſtinguiſhed at the pot-houſes accordingly, as twos, ſixes, twelves, ſixteens, twenty-fours, thirty-twos, forty-eights, ſixties, or ſixty-fours, &c. in each caſt; each pot having one or more apertures at bottom to diſcharge the ſuperfluous moiſture. They are ſold by the potters at ſo much per caſt, large and ſmall, all of a price; thoſe of only two in a caſt the ſame as thoſe of ſixty; and from two ſhillings to half a crown per caſt is the general price. See Pots.

But with reſpect to the particular method of Planting in pots in general, the following particulars are neceſſary to be obſerved.

Having the pots and mould ready for the reception of the intended plants, obſerve previous to planting them to place ſome pieces of tile, potſherds, or oyſter-ſhell over each hole at the bottom of the pots, both to prevent the holes being clogged and ſtopped with the earth, and the earth from being waſhed out with occaſional watering; alſo to prevent the roots of the plants getting out; then having ſecured the holes, put ſome earth in the bottom of each pot, from two or three to five or ſix inches or more in depth, according to the ſize of the pot, and that of the roots of the plant; this done, inſert the plant in the middle of the pot upon the earth, in an upright poſition, making its roots, if without a ball of earth, ſpread equally every way; directly adding a quantity of fine mould about all the roots and fibres, ſhaking the pot to cauſe the earth to ſettle cloſe thereto; at the ſame time, if the root ſtand too low, ſhake it gently up as you ſhall ſee occaſion; and, having filled the pot with earth, preſs it gently all round with the hand, to ſettle it moderately firm in every part, and to ſteady the upright poſture of the plant; raiſing the earth however within about half an inch, or leſs, of the top of the pot, it will ſettle lower; for ſome void ſpace at top is neceſſary to receive waterings occaſionally: as ſoon as the plant is thus potted, give directly a moderate watering, to ſettle the earth more effectually cloſe about all the roots, and promote their rooting more expeditiouſly in the new earth; repeating the waterings both before and after they have taken root, as occaſion requires.

In tranſplanting plants in pots from one pot to another, they may for the general be ſhifted with the whole ball of earth contained in the pot about their roots entire, ſo as to preſerve the plant all along in its growing ſtate, as ſcarcely to ſhrink or retard its growth by the operation of removal; which to plants growing ſingly in pots, and of ſome ſtanding, whoſe roots and fibres have eſtabliſhed themſelves firmly in the earth, they will readily remove out of the pots with the entire ball in one compact lump, ſurrounding all the roots and fibres, retaining their growing ſtate by ſtill drawing from the ſurrounding ball of earth.

The method of removing them out of the pots with balls, is generally eaſily effected to moſt potted plants. Sometimes it is performed by turning the pot mouth downwards, and ſtriking the edge againſt ſomething; the plant will come clean out, with the whole about all the roots entire. Or, ſometimes plants that are very well rooted, and its numerous fibres ſurround the outſides of the ball, it will often readily quit the pot by drawing it by the ſtem; or at leaſt, if raiſed a little from the ground, and ſtrike the edge of the pot or tub, the ball will often come out whole and compact. But if by either of the above methods the ball will not readily quit the pot, thruſt ſome narrow thin inſtrument of iron, ſuch as a long blade of a knife, &c. down round the ſides, as already hinted, the ball will then come out with much greater facility. Sometimes however large plants of ſome years ſtanding unſhifted, will by their encreaſed roots have ſo wedged themſelves, as to require the pot to be broken in order to preſerve the ball. And ſometimes large plants

in heavy tubs, ſuch as orange aad lemon-trees, require to be ſlung by the ſtems upon ſome temporary erection, to draw them out of the tubs with the ball entire.

Having however removed any plant with its ball for replanting in a larger pot, obſerve preparatory to Planting it, that as ſometimes the numerous fibres will have ſo ſurrounded the outſides of the ball, as to form a ſort of mat all around, it is proper to trim the groſſeſt of them off cloſe with a knife, all round the ſides and bottom; then having the pots of proper ſizes, larger than the former ones, and having ſecured the holes at bottom, and put in ſome freſh compoſt, depoſite the plant with its entire ball in the pot, minding that it ſtands erect, and juſt the proper depth; and fill up the interſtice all round the ball with more freſh mould, preſſing it down round the ſides with your hands or a ſtick, adding more mould gradually; and raiſe the whole about an inch over the crown of the ball, and finiſh with a moderate watering to ſettle the new earth cloſe in every part.

But in tranſplanting from one pot to another with balls, is in ſome caſes to be avoided; for example, if a plant appears diſeaſed or in a bad ſtate of growth, it is moſt probable the fault is in the root or earth; therefore in tranſplantation it is eligible to ſhake the whole entirely out of the earth, in order to examine its roots, and trim off all decayed and other bad parts; then, having a freſh pot, and ſome entire new compoſt, replant your tree, &c. therein, as already directed.

In potting plants from the full ground, or beds of earth, &c. that, if they have been previouſly pricked out at certain diſtances, and have ſtood long enough to fix their roots firmly, many ſorts may alſo be potted with balls, particularly moſt of the herbaceous, fibrous-rooted kinds, by taking them up carefully with a garden trowel, or with a ſpade, as may be moſt convenient; and, if neceſſary, pare the balls round to fit the pot, planting them as above.

Potting of ſeedling plants however immediately from ſeed beds, that, by their growing ſo cloſe together, rarely admit of potting with balls to their roots; ſo that when intended to pot ſuch, they muſt be drawn out of the earth with the root as entire as poſſible, and potted ſeparately in ſmall pots, ſhifting them occaſionally into larger, as before obſerved.

Sometimes in Pot-Planting, we, to ſave room, plant ſeveral plants in each pot, eſpecially when deſigned as nurſery pots, to receive either ſmall ſeedlings, off-ſets, ſlips, cuttings, &c. juſt to ſtrike them, and forward them a little at firſt, either in hot-beds, or for removing them to different ſituations, ſuch as occaſional ſhade, ſhelter, &c. but when ſuch ſeedlings are a little forwarded, or the off-ſets, ſlips, cuttings, &c. are properly rooted, and ſhoot a little at top, they ſhould be all potted off ſeparately, each in a ſeparate pot, eſpecially if plants of any duration; giving them ſmall pots at firſt, and as they encreaſe in ſize, ſhift them into larger pots accordingly.

When any large growing plants, ſuch as orange and lemon-trees, or any other kinds, are become too large for pots, they ſhould be ſhifted into tubs: theſe tubs ſhould be made of full inch-thick ſtaves, and adapted to the ſize of the reſpective plants; each tub well hooped with iron, and with two hooked iron handles at top, to receive poles between two men for moving the plants where occaſionally wanted; having holes at the bottom of the tubs to diſcharge the ſuperfluous moiſture, as obſerved for the pots; placing ſome ſtones, &c. to prevent the holes being clogged with the earth; the method of planting and tranſplanting being the ſame as in Pot-Planting.

In the culture of all plants in pots it is proper to ſtir the ſurface of the earth now and then an inch or two deep, to prevent its binding or becoming moſſy, and to promote the growth and health of the plants: likewiſe to ſuch as are not ſhifted annually, it is alſo proper to add a little freſh mould in ſpring and autumn, previouſly ſtirring the old at top as above, and a little way round the ſides; then taking out the old, replace it with an equal portion of freſh compoſt, finiſhing with a moderate watering; this will prove a very beneficial dreſſing to the plants, and give an air of neatneſs, and a more lively appearance to the whole.

In all plants in pots or tubs great care is requiſite in ſupplying them with water, which muſt be obſerved to moſt ſorts the year round, but more particularly in ſummer; for the earth containing the plant being limited to the compaſs of a ſmall pot or tub, it dries very faſt in hot weather, ſo muſt be often moiſtened accordingly; which to ſome plants may be requiſite three or four times a week in the ſummer ſeaſon; and to ſome ſorts in ſmall pots every day, or even twice a day in very

very dry ſcorching weather: but as the autumn and cold ſeaſon advances, give the waterings more ſeldom and ſparingly; and in winter, plants that are expoſed abroad in pots rarely require any water at all; but thoſe in the green-houſe or other place of ſhelter muſt be watered occaſionally alſo during the winter; ſome probably once a week, or ten or twelve days, ſuch as all the woody kinds; others but once a fortnight or month, particularly the ſucculent kinds; and ſome of the more tender very ſucculent ſorts will require very little moiſture at any time, but eſpecially in winter; being careful however always to water all ſorts in pots moderately in this ſeaſon of the year, and let it always if poſſible be done in ſunny days, and give very little in froſty weather: at no time give too much to render the earth miry wet in winter, which would prove the deſtruction of moſt tender exotics; all that is neceſſary is to preſerve the earth very moderately moiſt. Potted plants in hot-houſes however will require more frequent ſupplies of water in winter than any other plants in pots.

To potted plants in general we muſt occaſionally examine that the holes at bottom are ſufficiently open to diſcharge the ſuperfluous moiſture from occaſional waterings, &c. for if theſe are clogged up, and detain the moiſture, the conſequence will be bad, for it will rot the fibres, and even the main root, and ſoon bring on the decay of the whole plant; however by turning up the bottom of the pot, the holes if ſtopped are eaſily cleared with the end of a ſtick or other inſtrument.

### *Other general Obſervations of Tree Planting in particular.*

Having exhibited above the various methods of performing the mechanical operation of Planting, we will next give ſome hints with reſpect to the preparation of plants previous to Planting, particularly of tree Planting, which being of the greateſt importance, ſhall firſt exhibit ſome general remarks on that head.

In the firſt place obſerve, with reſpect to Planting trees of all kinds, that it is of conſiderable importance to give them their final tranſplantation whilſt they are young, i. e. from about two or three to ſix or ſeven years old, and when of from about two or three, to ſix or ſeven feet ſtature; eſpecially for all kinds of fruit-trees and foreſt-trees for long duration; as at the above ages and ſtatures they will eſtabliſh themſelves ſooner and more firmly in the ground than trees of more conſiderable age and growth, and in the end make the moſt proſperous and durable trees.

Note, however, trees ten, fifteen, or twenty feet high are occaſionally tranſplanted, eſpecially ſome deciduous foreſt and ornamental trees in particular caſes; in forming ornamental plantations, where perſons are in haſte to have any part thereof appear conſpicuous as ſoon as poſſible, or to afford immediate ſhade or ſhelter, as to form blinds to any particular compartment.

But there are many ſorts of trees and ſhrubs of eight, ten, or twelve feet ſtature, both deciduous and evergreens, that may be readily tranſplanted with tolerable ſucceſs; as, if taken up with a good ſpread of roots, they will take root freely, and often aſſume a good free growth; theſe ſizes however are more proper to be employed occaſionally in ornamental plantations, to exhibit immediate ſhew, than for any general plantations of fruit and foreſt-trees.

And as to trees of fifteen or twenty feet height or more, although they may on particular occaſions in ornamental works be tranſplanted, by care in removing them with a good compaſs of roots, or ſometimes with balls, as may occaſionally be practiſed to ſuch in particular that happen to grow on graſs ground; and are not to be removed to any great diſtance; yet the tranſplantation of theſe large trees ſhould not be attempted for any general purpoſe, but only in caſes where a few trees may be required to form an immediate ſhew in ſome particular compartment, or to form preſent ſhade, ſhelter, or blind, as aforeſaid, till younger trees grow up; for they rarely eſtabliſh their roots like younger growth, but often aſſume a ſtunted habit, and frequently after a few years dwindle gradually off; ſo that when ſuch are employed, it is proper to have ſome younger trees near them to be advancing as ſubſtitutes if any of the others ſhould fail.

However, for any general plantations, either of fruit-trees, foreſt-trees, or ornamental trees and ſhrubs, let them be compoſed principally of young plants from about two or three to ſix or eight feet height, as theſe ſizes will be found to root more expeditiouſly and effectually, as well as ſhoot more freely at top than large tranſplanted trees, and ſooner attain a ſtate of perfection.

But foreſt-trees in particular, that are intended principally for timber plantations, it is moſt eligible to plant them out finally when

from two to four or five feet high, that they may eſtabliſh their roots firmly in their minor ſtate, which is of conſiderable importance in promoting a flouriſhing and durable growth, ſo as they may ſooner attain a great ſtature and magnitude.

In the work of Planting trees, &c. the choice of them in the nurſery for furniſhing the reſpective plantations ſhould be particularly attended to; that, whether in your own ground, or in the public nurſeries, always chuſe the ſtraiteſt, moſt vigorous, and thriving plants of the reſpective kinds.

Likewiſe in preparing for Planting, obſerve that in taking up the trees for that purpoſe out of the nurſery, the greateſt care is neceſſary in raiſing them with as great a ſpread of roots as poſſible; which however is often ill attended to, eſpecially when large orders of plants are to be drawn in a hurry. The ground about the trees ſhould always be opened with the ſpade widely round the roots, and deep enough to get to their bottom without hacking and cutting them with the ſpade, but ſo as to raiſe each plant with all its roots as entire as poſſible, for this is of much importance in the future proſperity of the trees and ſhrubs.

After having taken up the trees out of the nurſery, &c. it is of great moment to have them replanted as ſoon as poſſible in the places allotted for them; for, although by properly covering the roots with litter, or, if ſent to any conſiderable diſtance, that by tying them in bundles, and packing them up with plenty of ſtraw about the roots, and afterwards cloſely matted round, they may be preſerved in tolerable good condition a fortnight or longer; yet where it is poſſible to plant them the ſame day, or in a day or two after, before the ſmall fibres are ſhrunk or dried, it will be of much advantage in the firſt growth of the trees; obſerving however, after trees or ſhrubs are taken up in order for Planting, and that either the ground not being ready, or any other hindrance prevents their being planted ſoon after, they ſhould as ſoon as poſſible be depoſited in a trench of earth by the roots, which gardeners call *laying them by the heels*, and ſo take them out as they are to be planted.

Next with reſpect to preparing the trees for planting, after being drawn out of the nurſery.

In the firſt place with regard to the root; this part muſt have an occaſional trimming, not however to retrench or reduce any but the maimed and decayed parts; therefore previous to planting each tree, examine the root, and cut out all ſuch parts as have been broken or damaged in taking up, and all decayed parts and other blemiſhes, being careful to leave all the ſound roots every where entire; leaving alſo all the ſmall fibres that are freſh and vigorous, and only trim off ſuch as are become dry and mouldy; ſuffering all the main roots to remain, moſtly at full length, except juſt to tip off their ends a little on the under ſide, ſloping outward; and reduce any very long ſtragglers, and ſhorten long perpendicular tap-roots, more particularly of fruit-trees, to prevent their running down into a bad ſoil, and promote their throwing out others horizontally into the good earth.

Some perſons however make it a rule to retrench or thin the roots of tranſplanted trees very much, and ſhorten them alſo very conſiderably; but it will be found that trees planted with all their ſound roots, will be the moſt proſperous in growth; for the reducing the roots with too much ſeverity, greatly weakens the tree; and, as every one muſt know, that all plants and trees receive invigoration, and their moſt eſſential nouriſhment from the roots and fibres, ſo that it is certainly an act of high imprudence to deſtroy the roots of any tree that are good and ſound in every reſpect, and wait a conſiderable time for new ones, when we are actually poſſeſſed of a ſufficiency that are good; it is therefore conſequently the ſafeſt way to leave all the good roots, and only retrench blemiſhed and decayed ones, as already obſerved.

And with regard to the preparation of the head of the trees previous to Planting, the principal care is to trim off ſtraggling ſhoots and branches from the ſtem, leaving the head for the generality intire, only juſt retrenching very irregular branches, and ſhortening any very long ſtragglers; and always ſuffer the main or leading top ſhoot to remain at length, to aſpire in height as faſt as poſſible, particularly foreſt-trees, and all others that we deſign ſhall grow to a lofty ſtature, for in this conſiſts their beauty and worth.

With reſpect to fruit-trees however, ſometimes a more accurate regulation of the head preparatory to Planting may be requiſite, more particularly dwarfs for eſpaliers and walls. For example, if the fruit-tree is taken from the nurſery at one year old from the budding and grafting, and with its firſt ſhoot from budding and grafting entire; this firſt ſhoot muſt neceſſarily be ſhortened or headed down

down to force out lateral wood to furniſh the bottom properly; but obſerving this heading down is not neceſſary at the time of Planting, and is moſt eligible to plant the tree with its ſaid firſt head entire, to remain till ſpring, until the tree has taken freſh root and begins to ſhoot; for the head remaining will greatly promote the rooting: then in March or beginning of April, the tree having taken root, as you will obſerve by its effort for ſhooting at top, head it down within half a foot, or five or ſix eyes of the inſertion of the bud or graft, and the ſhoot ſo headed will throw out ſeveral lateral branches the enſuing ſummer.

On the other hand, if the fruit-tree is two, three, or more years old from the budding and grafting, and the firſt ſhoots headed down in the nurſery at the proper time, and that in conſequence thereof, produced ſeveral lateral ſhoots, to give the head its firſt formation; or even if the tree has ſtood long enough to form a good full head, it is proper in both caſes to plant it with its whole head entire; only retrenching any irregular branch, or any very luxuriant ſhoot; or thin out the worſt of ſuch as are evidently too cloſe or crowded, leaving however all the regular branches, ſuffering them to remain alſo at full length, except juſt to reduce any very long rambler conſiſtent with the extent of the other branches.

For in new Planting trees it is very improper to retrench the branches too ſeverely, and cut all that remains ſhort, as is very often practiſed in tranſplantation, on a ſuppoſition to ſtrengthen their roots, which however has often the contrary effect; for the branches and leaves imbibe the refreſhing influence of the air, &c. which, being conveyed to the roots, proves nutrimental, and contributes exceedingly towards vegetation, and conſequently promotes the rooting afreſh more expeditiouſly and effectually; and until this is well effected the tree will make but little progreſs in its top growth.

Beſides, by a ſevere retrenching, and a general ſhortening, of fruit-trees in particular, they cut off the very parts where fruit would have been ſoon firſt produced; and probably coſt the tree two or three years growth to furniſh new branches equal to thoſe cut away, as well as retard its bearing in proportion. And it often happens by ſuch a general amputation of the branches of all new planted trees at the time of Planting, they, for want of branches to collect vegetative nouriſhment, either make very little progreſs in ſhooting for two or three years after; or ſometimes when they do ſhoot, throw out a profuſion of unneceſſary wood from the remaining eyes or buds.

For, as we formerly obſerved, that although ſhortening the branches of fruit-trees in particular is ſometimes proper in young trees of one or two years old from budding or grafting, to force out a ſupply of lateral wood to furniſh the firſt regular formation of the head, more particularly dwarfs for eſpaliers and walls; yet if you are about to tranſplant the tree, and the operation of heading being neceſſary as above, it ought not to be done till after the tree is planted, and has began to take root and make an effort for ſhooting in March or April; for when headed down at Planting, they, for want of the head, rarely either ſtrike root or ſhoot at top ſo freely.

Therefore if fruit-trees at Planting, whether dwarfs or ſtandards, are furniſhed with five or ſix or more good regular branches, of one, two, or more years growth, it would be a great pity to retrench them, and diſfigure the tree, either on the conſideration of ſtrengthening it, or to force out more branches; particularly apples, pears, plums, and cherries, which ſhould at all times be but ſparingly ſhortened; and ſince ſeveral good branches being already obtained in the proper parts, to give the head its firſt regular form, they will in their turn readily furniſh more; and if there is a vacancy in any part, it will be better to endeavour to fill it by ſtopping ſome of the young ſhoots produced the ſummer after Planting, by either pinching them in May or June the ſame year to three or four eyes, or cut them down to that length in winter or ſpring following.—Some fruit-trees however, ſuch as peaches, nectarines, &c. againſt walls, require moſt of their young ſhoots to be ſhortened annually.—But for more particulars of all the ſorts, ſee their reſpective genera.

Standard fruit-trees, when deſigned they ſhall form ſpreading heads, branching out near the top of the ſtem regularly all around, they, if grafted high in the ſtem, muſt, like the dwarfs, have alſo the firſt ſhoot from the budding or grafting, headed down to four or five eyes, to force out a ſet of lateral branches near the inſertion of the bud or graft; or, if the grafting and budding was performed near the ground, and the firſt ſhoot trained to a proper height for a ſtem, it is alſo topped at the deſired height, to throw out a ſupply of lateral branches each way, near the head of the ſtem, as above ſaid; but ſometimes when the firſt heading,

in either of the above methods, does not furniſh a proper ſupply of branches to give the head its firſt proper formation, a ſecond heading is occaſionally performed the next ſpring, upon the ſhoots produced from the firſt; obſerving, however, that all the above works of heading ſtandard fruit-trees, in particular, ſhould always be performed in the nurſery a year or two, or more, previous to final tranſplantation into the garden or orchard, that the trees may be furniſhed with ſeveral regular branches to form a head, at the time of Planting; and, as before obſerved, it is proper to plant it with all its ſaid head entire; except reducing ſuch irregular growths as already mentioned, ſo leaving all the regular branches at their length, ſuffering the whole to ſhoot up, and branch away in their own way; and they will annually advance in length, and gradually furniſh laterals to fill and ſpread the head proportionably.

But remarking particularly that ſtandard-fruit-trees, having been previouſly headed in the nurſery a year or two or more before, and in conſequence are now furniſhed with ſeveral regular branches of one, two, three, or more years growth, they ſhould on no conſideration be either retrenched or ſhortened, neither at Planting nor afterwards, for the reaſons before given; and alſo that as moſt fruit-trees begin to bloſſom and bear firſt towards the upper parts of the branches, more particularly apples, pears, plums, and cherries, which always produce their fruit upon ſhort ſhoots called *ſpurs* or *fruit-buds*, that moſtly riſe firſt towards the ends of the branches; but which in this ſhortening would all be cut away, and retard the bearing two or three years, beſides all the other diſadvantages above mentioned.

But when ſtandard fruit-trees are required to aſpire more conſiderably in height, rather ſomewhat pyramidal, or conic ways, than horizontally; no heading at all ſhould be practiſed, neither in the nurſery, nor at the time of final Planting; but the whole, quite from the budding or grafting, ſuffered to remain entire, and ſhoot up, and branch according to nature; and they will naturally form a regular head. Some ſorts ſpherically, others more of the pyramidal, or conic figure.

As to foreſt-trees, &c. their preparation, previous to Planting, after being drawn out of the nurſery, is only to trim the blemiſhed roots, as before obſerved; and prune off all branches from the lower part of the ſtem, cutting them to about from three to five or ſix inches, particularly the deciduous kinds, leaving the head always tolerably branchy, and moſtly entire; not to trim away all the branches to one leading ſhoot only, as is often practiſed; but leave a proportionable ſhare of the upper more erect branches, to form ſome head, and only juſt retrenching the lower ſtragglers, very long rambling luxuriants, and very irregular growths, juſt to preſerve a little regularity; being particularly careful to leave always the top or leading ſhoot perfectly entire; unleſs it is decayed, or is very crooked, bending much downwards, &c. in which caſes, if any ſtraight ſhoot is conveniently ſituated, the crooked part may be retrenched down to the ſtraight ſhoot, which leave entire to run up in height; as without a leader a tree can never aſpire to any conſiderable ſtature: for the leader, by its annual erect ſhoot, gradually encreaſes the length of the ſtem, and as it advances, ſends out a ſupply of laterals to furniſh the head, branching and ſpreading in proportion, according to the natural growth of the reſpective ſorts.

But in Planting tall trees, where deſigned to form ſhade, ſhelter or blinds, as ſoon as poſſible, very little reduction of the branches of the head may be neceſſary, only to reduce any very irregular growers.

However, in removing pretty large trees of any ſort, with conſiderable heads, eſpecially of a very ſpreading or crowded nature, it may be proper to reduce the whole regularly, both in ſome proportion to the root, and that the winds may not have too much power to incommode it after Planting; in which caſes, it may be neceſſary, as juſt above obſerved, to retrench, or reduce ſome of the moſt extenſive lower branches; thin out ſome where much crowded, and reduce others down to ſome convenient lateral branch they may ſupport; ſo as each reduced branch may, notwithſtanding its reduction, terminate in a leader, having its top entire, not to exhibit naked ends of branches, ſtanding up like ſtumps. Obſerving, however, in ſuch large trees, that the above reduction ſhould be ſo judicious, as the remaining branches may ſtill exhibit a moderately full, and ſomewhat regular head.

With reſpect to the preparation for Planting of all the ſhrub kind, only juſt trim ſtraggling under-branches and ſhoots from the lower part of the ſtem; retrench luxuriants of the heads that ſeem to ſhoot away very irregularly

regularly and vigorouſly, at the expence of the neighbouring branches; and reduce long ramb'ers, &c juſt to preſerve a little regularity.

All new planted tall trees, ſhould generally be ſtaked as ſoon as planted, in order to ſupport them ſteady every where, till well rooted, and have ſomewhat eſtabliſhed their roots, that tempeſtuous winds may not overſet, or otherwiſe incommode them; particularly all trees of ſix or ſeven feet high, and upwards. One tall ſtout ſtake to each tree, or more, if the trees are of large ſize, ſharpening the lower ends, and drive them firmly into the ground near the ſtem; or, if larger trees, place it ſlant-ways, at a little diſtance, ſo as its top reach the upper part of the ſtem, on the oppoſite ſide to that moſt expoſed to the winds, in which it will have the greateſt effect; but large trees, with full heads, ſhould generally have very tall ſtrong ſtakes, three to each tree, placed triangular ways, alſo in an oblique or ſlanting direction. Having, however, fixed the ſtakes in either of the methods, as the trees ſhall require, then directly proceed to bind the ſtem of the trees firmly to the ſtakes, previouſly wrapping ſome ſoft ſubſtance, ſuch as hay-bands, &c. round the ſtem, at the part where it is to be faſtened to the ſtakes, in order to ſave the bark from being rubbed off againſt the ſtakes, by the motion of the winds: and this is more particularly neceſſary to tall plants that are much expoſed. Having ſome ſtrong bandages, ſuch as rope-yarn, or the like, or for ſmaller plants ſome tough oſier or other withies, then bringing the ſtem and ſtakes cloſe, ſo as to preſerve ſtill the erect poſition of the plant, bind them firmly together, by drawing the bandage round the ſtakes, and about the ſtem, over the hay wrapping, if any, and faſten it ſo ſecurely, as to admit of no motion between the ſtake and ſtem of the tree.

But large trees, of ſome conſiderable ſtature, with full heads, are often ſupported alſo with ropes ſuſpended from the top of the ſtem, three different ways, ſtraining them tight, and the end of each rope ſtaked ſecurely down to the ground; ſo that, whatſoever way the wind blows, the ropes will ſtay the tree ſtill in its upright poſition.

Such new planted trees as are expoſed to cattle, ſhould each be well fortified all round the ſtem with thorn buſhes.

The general Planting ſeaſon, for all ſorts of trees, is, autumn and ſpring, i. e. the autumnal Planting being from the beginning of the decay of the leaf, in October, until December; though ever-greens may be begun to be tranſplanted towards the middle or latter end of September, and continued till December aforeſaid. And for the ſpring Planting, February and March is the principal time, but may be continued occaſionally until April; and ſeveral ſorts of tender young ever greens ſucceed beſt when planted the beginning of that month.

However, to thoſe perſons that have much Planting or other buſineſs in hand, I would obſerve, that Planting need not be confined particularly to autumn and ſpring; for all hardy kinds, both fruit-trees, foreſt-trees, ſhrubs, &c. may be planted occaſionally, almoſt any time, in open weather, from October till March, eſpecially in all moderately dry ſoils, with good ſucceſs.

Planting, however, forward in autumn, is of ſome advantage, as the trees will have time to root more firmly, ready for the enſuing ſpring ſhoot, as well as be able to ſtand the drought of ſpring and ſummer ſomewhat better than thoſe planted later.

But in very humid ſoils, where water is apt to follow the ſpade in winter, it is eligible always to plant forward in autumn, or not till ſpring; but rather principally the laſt mentioned ſeaſon, toward the latter end of February, or in March.

*Farther Obſervations, particularly in Planting herbaceous Plants.*

In preparing to plant herbaceous fibrous-rooted plants, our firſt principal care is to remove them, with good roots: young ſeedlings, &c. eſpecially require particular care in drawing them with proper roots. When they are to be taken all clean up, they may be readily looſened and raiſed out of the earth with ſome inſtrument, with all their fibres entire; but when they are only to be thinned, they do not admit of this, becauſe it would diſturb the remaining plants, ſo muſt be drawn out by hand carefully, with as much root as poſſible.

Many ſorts of fibrous-rooted plants, however, being ſo hardy, and apt to grow, that if taken up almoſt any how, with a little root, they will often ſtrike: it is nevertheleſs adviſeable to uſe care in drawing all ſorts for Planting, with tolerable roots, as they will in proportion make more progreſs in their future growth. And as to any trimming preparatory to Planting, very little is wanted,

only

nly in ſome ſorts, juſt ſhortening very long naked ſpindly roots, and trimming any ſtraggling fibres; though in numbers of plants of this tribe hardly any trimming at all is required, neither in root nor top; all of which however you will be able to regulate according to obſervation, agreeable to the hints here exhibited, and in the culture of the reſpective articles.

The moſt commodious and expeditious mode of Planting herbaceous ſeedlings, ſlips, offſets, cuttings, &c. is by dibble, as already obſerved in *Planting by Dibble*; and for ſuch as have been previouſly pricked out in nurſery-rows, many ſorts may be drawn with little balls, when required, and holed-in with a trowel, eſpecially numbers of the choiceſt flowery tribe; but almoſt all ſorts of pricked-out herbaceous fibrous-rooted plants may either be drawn with full roots, and planted by dibble, or with balls of earth, and holed in by trowel, as ſhall ſeem moſt convenient according to the nature of the plants.

Many ſorts of fibrous-rooted plants may be planted out at once, where they are finally to remain, particularly all long ſpindly-rooted kinds; likewiſe numerous others of the more fibrey-rooted ſorts may alſo be planted out finally from the ſeed-bed, provided the ground is ready for their reception; yet I would obſerve when the ground is not ready to receive them for ſome conſiderable time, it will be eligible to thin-out a quantity from the ſeed-bed, and prick them in nurſery rows five or ſix inches aſunder, to remain a month or ſix weeks or longer, till the ground is ready for their reception, whereby they will acquire good roots, and a robuſt firm growth, in order for final tranſplantation; whereas when they all remain long in the ſeed-bed, they by ſtanding ſo cloſe, draw each other up very ſlender and weak, and never make near ſo good plants as thoſe previouſly thinned and pricked out at ſmall diſtances; which, after growing a month or two in nurſery rows, will all readily riſe with full roots for final Planting, and many ſorts alſo with good balls of earth where neceſſary, which may be more particularly requiſite to ſome of the choice, flowery tribe.

The ſeaſon for Planting moſt herbaceous fibrous-rooted plants is any time in ſpring, ſummer, and autumn, according as they may be required for different purpoſes, as is always hinted in the culture of the various ſorts; and many hardy kinds even in winter, in mild open weather, when occaſionally wanted; for moſt of this tribe of plants readily and expeditiouſly take root at almoſt any ſeaſon, in mild weather; chuſing generally moiſt weather in ſpring and ſummer, but eſpecially from April until September; and chiefly dry weather for winter Planting: obſerving likewiſe in the ſpring and ſummer Planting, it is proper always to give a moderate watering as ſoon as planted, but eſpecially in ſummer, unleſs it ſhould happen to rain hard enough to deſcend to the roots; otherwiſe a little water to ſettle the earth cloſe to the roots is of very eſſential ſervice.

As to Planting herbaceous bulbous-rooted plants, ſuch as hyacinths, narciſſus, tulips, and all others of the bulbous tribe, they ought never to be removed but only in ſummer, when their ſtalks, leaves, and fibres of the bulbs decay; for theſe parts of bulbous plants always decay annually in ſummer, ſoon after they have flowered and ripened ſeeds; but the bulbs themſelves are perpetuated; ſo that the above period is the time either to plant out ſeedlings of theſe ſorts previouſly into nurſery-beds for two or three years or more, to acquire a proper age and ſize for flowering, then tranſplanted finally: it is alſo the proper period for tranſplanting full-grown bulbs, either from one place to another directly, or take them up to keep for autumn and ſpring Planting.

All bulbous-rooted plants taken up at the above time of the decay of the ſtalks, leaves, and fibres, may either be planted again directly, or kept till September, October, or November, and then planted; which for the choiceſt ſorts is the moſt eligible practice, as obſerved in their culture: and in order to have a late bloom a few may alſo be retained out of ground till ſpring, about January or February; but plant the principal always in autumn, about October and November.

Bulbous plants are planted two or three different ways, as by dibble, by drilling-in, and by bedding-in. See each of theſe methods as exhibited ſeparately under this article PLANTING.

Chuſe always dry weather for Planting moſt kinds of bulbs, eſpecially all the choice kinds.

PLATANUS, Plane Tree.

This genus conſiſts of lofty deciduous trees, of high repute for their ſingularly beautiful growth and luxuriant foliage; being delightful trees for all ornamental plantations, and for affording ſhades; alſo as foreſt or timber-trees, they growing remarkably ſtrait to a conſiderable height and magnitude; adorned with

with very large ſimple, palmated and lobated leaves, from ſix to twelve or fourteen inches broad, but very ſmall monoeceous flowers, collected into cloſe globular heads, ſucceeeded by numerous ſeeds, digeſted into large round rough balls.

Claſs and order, *Monoecia Polyandria.*

*Characters.*] CALIX, male and female, very ſmall flowers; apart on the ſame plant, the male florets digeſted into globular katkins, having very ſmall cups; and females collected into a large roundiſh ball, having very ſmall ſcaly calixes. COROLLA in the males is ſcarcely diſcernible, and in the females each floret having many ſmall concave petals. STAMINA, numerous, ſmall, oblong, coloured filaments, having four-cornered antheræ. PISTILLUM, ſeveral ſubulated *germina*, having ſubulated ſtyles, and recurved ſtigmas. PERICARPIUM, none, numerous roundiſh ſeeds, ſurrounded with down, and collected into round hard balls.

There are only two real ſpecies; which, however compriſe ſome varieties, all of which are deciduous, and of hardy growth.

The ſpecies are,

[1]PLATANUS *Orientalis.*

*Oriental or Eaſtern Plane Tree.*] Riſes with a very ſtraight, ſmooth, branching ſtem, to a great height; palmated leaves, ſix or eight inches long, and as much broad, divided into five large ſegments, having the ſide ones cut into two ſmaller, green above, and pale underneath; and long pendulous pedunculi, each ſuſtaining ſeveral round heads of cloſe-ſitting, very ſmall flowers; ſucceeded by numerous downy ſeeds, collected into round, rough, hard balls.

It is a native of Aſia, and many parts of the Eaſt, and grows in great plenty in the Levant.

[2]PLATANUS *Occidentales.*

*Occidental or Weſtern Plane Tree.*] Riſes with a ſtraight ſmooth ſtem, to a great height, branching widely around; lobated leaves, ſeven or eight inches long, and from nine or ten, to twelve or fourteen broad, divided into three large lobes; and very ſmall flowers, collected into round heads, ſucceeded by round, rough, balls of ſeed.

It is a native of Virginia, and other parts of North America; where it attains an enormous ſize, and is remarkable for having its ſtem all of an equal girt for a conſiderable length; and we have an account of ſome trees being eight or nine yards in circumference, and when felled, afforded twenty loads of wood.

Varieties of theſe two ſpecies, are,

*Spaniſh or middle Plane Tree.*] Having remarkably large leaves of three or five narrower ſegments.

*Maple-leaved Plane Tree.*] Having ſmalleſt leaves, ſomewhat lobated into five ſegments; reſembling the maple-tree leaf.

All theſe elegant trees are of hardy temperature; ſo as to proſper here in any common ſoil, and expoſure in our open plantations, &c. and are ſome of the moſt deſirable trees of the deciduous tribe; were in ſingular eſteem among the ancients of the Eaſt, for their extraordinary beauty and delightful ſhade they afforded, by their noble foliage.

The leaves commonly expand in May, and fall off early in autumn; and the flowers appear in ſpring, a little before the leaves, being ſucceeded by ſeeds, which, in fine ſeaſons, frequently ripen here in September.

As to the uſes of theſe fine trees in gardening; they have ſingular merit for all ornamental plantations; their ſtraight growth, regular branching heads, and lofty ſtature they attain, together with the extraordinary breadth of their luxuriant leaves, render them extremely deſirable furniture to adorn avenues, lawns, parks, and woods; ſome diſpoſed in ranges; ſome as ſingle ſtandards; others in clumps; ſome in groves, &c. and are moſt excellent for ſhade; for it is obſervable, that no tree is better calculated to defend us from the heat of the ſun in ſummer, by its noble ſpreading foliage, and to admit the ſun's rays more freely in winter, on account of the diſtance of its branches, which is always in proportion to the ſize of the leaves.

They may alſo be employed in the collection of foreſt trees, in woods, to grow up to timber, in which they will alſo prove advantageous in time.

In ſhort, theſe noble trees claim the eſteem of every one concerned in plantations of every kind; but more particularly in extenſive works, where they may be ſo variouſly diſpoſed, as to have a charming effect.

*Their Propagation.*

The propagation of theſe trees, is by ſeed, layers, and cuttings.

By Seed.—The ſeeds frequently ripen in theſe parts, and are alſo procured from other countries, and may be obtained of the nurſerymen, or ſeedſmen; obſerving, the beſt ſeaſon for ſowing them is autumn, if they can be then poſſibly procured. Chuſing a ſomewhat ſhady moiſt ſoil; and having dug the ground, and raked it fine, form it into four-feet wide beds, and either ſcatter the ſeeds evenly on the ſurface, and rake them in, or, previouſly with the back of a rake, turn the earth off the ſurface near half an inch deep into the alleys; then ſow the ſeed, and directly, with the rake turned the proper way, draw the earth evenly over the ſeeds, and trim the ſurface ſmooth; many of the plants will riſe in ſpring, and probably may not till the ſpring following. When they are one or two years old, plant them out in nurſery rows, two or three feet aſunder, and about half that diſtance in the lines; here to remain till of a proper ſize for final tranſplantation.

By Layers.—This method of propagation is very commonly practiſed in the nurſeries, in default of ſeed, and by which they moſt readily grow; for which purpoſe, ſome ſtout plants for ſtools muſt be planted, which in a year after muſt be headed down near the bottom, that they may throw out many ſhoots near the ground, convenient for laying; which, in the autumn after they are produced, lay by for ſlit-laying; and by autumn after, they will be well rooted, and form plants two or three feet high, ſo may be ſeparated, and planted in nurſery rows, like the ſeedlings.

By Cuttings.—All the ſorts will take tolerably by cutting off the ſtrong young ſhoots; but the *Platanus Occidentalis* more freely than the Oriental kind. Autumn is the beſt ſeaſon; as ſoon as the leaf falls, chuſing ſtrong young ſhoots, and plant them in a moſt ſoil; many of them will grow, and make tolerable plants by next autumn.

It ſhould be remarked, that in order to continue the diſtinction of the varieties more effectually, they ſhould be propagated either by layers or cuttings: for when raiſed from ſeed, thoſe of the reſpective ſpecies generally vary.

PLEASURE-GARDEN, or Pleaſure-ground.

The diſtrict commonly called the Pleaſure-ground, may be ſaid to comprehend all ornamental compartments, or diviſions of ground and plantation, ſurrounding a noble ſite, conſiſting of lawns, plantations of trees and ſhrubs, flower compartments, walks, pieces of water, &c. whether ſituated wholly within the ſpace generally conſidered as the Pleaſure-garden, or extended over ha-ha's to the adjacent fields, parks, paddocks, or other out-grounds.

In deſigns for a Pleaſure-ground, according to modern improvements, conſulting rural diſpoſition, in imitation of nature, all too formal works being almoſt aboliſhed, ſuch as long ſtraight walks, regular interſections, ſquare graſs plots, correſponding parterres, quadrangular and angular ſpaces, incloſed with high clipped hedges, &c. and other uniformities, as in ancient deſigns; and inſtead of which, conſiſts now of rural open ſpaces of graſs ground, of irregular dimenſions, and winding walks, all bounded with plantations of trees, ſhrubs, and flowers, in various irregular clumps, and other compartments, exhibited in a variety of curves, projections, openings, and cloſings, in imitation of a natural aſſemblage; not forming incloſures of hedges, &c. but having all the various plantations open to the walks and lawns; for example: a ſpacious open lawn, of graſs ground, being generally firſt preſented immediately on the front of the manſion, or main habitation, having each ſide embelliſhed with plantations of ſhrubbery, groves, thickets, &c. in clumps and other compartments, in irregular curves, and projections, towards the lawn, &c. with breaks or opens of graſs ſpaces at intervals, between the plantation; together with ſerpentine gravel-walks, winding under the ſhade of the trees; irregular plantations, being alſo carried round next the outer boundary of the ground, in various openings and cloſings, having gravel-walks, winding through them, for ſhady and private walking; and in the interior diviſions of the ground is exhibited ſerpentine winding walks, and elegant graſs opens, arranging various ways, all bordered with ſhrubberies, and other tree and ſhrub plantations, flower compartments, &c. diſpoſed in a variety of irregular forms and dimenſions, in eaſy bendings, concaves, projections, and ſtraight ranges, occaſionally; with intervening breaks or opens of graſs ground, arranging irregularly between the compartments of plantations, &c. both to promote rural diverſity, and for communication and proſpect to the different

diviſions; all the plantations being ſo artfully arranged, as gradually to diſcover new ſcenes, each furniſhing freſh variety, both in the form of the deſign in different parts, as well as in the diſpoſition of the various trees, ſhrubs, and flowers, and other ornaments and diverſities.

So that in deſigns for a Pleaſure-ground, according to modern gardening, a tract of ground of any conſiderable extent may have the proſpect varied and diverſified exceedingly, in a beautiful repreſentation of art and nature, as that in paſſing from one compartment to another, ſtill new varieties preſent themſelves in the moſt agreeable manner; and even if the figure of the ground is irregular, and its ſurface have many inequalities, in riſings and fallings, and other irregularities; the whole may be improved without any great trouble of ſquaring and levelling, for by humouring the natural form, may cauſe even the very irregularities to conceal their natural deformities, and carry along with them an air of diverſity and novelty.

In theſe rural works, however, we ſhould not aboliſh entirely all appearance of art and uniformity; for theſe, when properly applied, gives an additional beauty and peculiar grace to all our natural productions, and ſets nature in the faireſt and moſt advantageous light.

But ſome of our modern Pleaſure-gardens, in which rural deſign is copied to an extreme, are often very barren of variety and entertainment, as they frequently conſiſt only of an extenſive graſs lawn, like a great field, having a running plantation of trees and ſhrubs all round, juſt broad enough to admit of a gravel walk, winding through it in the ſerpentine way, in many ſhort twiſts and turns, and bordering at every turn alternately upon the outward fence and the lawn; which are continually obtruded upon the ſight, exhibiting the ſame proſpect over and over, without the leaſt variation, ſo as that after having traverſed the walks all round this ſort of Pleaſure-garden, we find no more variety or entertainment than at our firſt entrance, for the whole having preſented itſelf at once at the firſt view; and we might often ſee as good a garden, ſometimes in a common field, that is bordered with any kind of plantation.

Therefore, in laying out a Pleaſure-garden, the deſigner ought to take particular care that the whole extent of his garden, be not taken in at one view; only exhibiting at firſt a large open lawn, or other ſpacious open compartment, or grand walk, &c. terminated on each ſide with plantations of curious trees, ſhrubs, and flowers, in compartments, exhibiting only ſome opens at intervals; and behind theſe have compartments of the like plantations, with graſs opens, gravel-walks, water, and other ornaments; ſo that a ſpectator will be agreeably ſurpriſed to find what terminated his proſpect, was an introduction to new beauties and variety.

But it is impoſſible to exhibit any regular directions for planning a Pleaſure-garden, agreeable to the prevailing modern deſign in imitation of nature aforeſaid; as the plan may be varied exceedingly, according to the natural figure, poſition, and ſituation of the ground and taſte of the deſigner; ſo we can only give ſome general hints.

*General Sketch of the Deſign.*

Take, however, the following general ſketch, which may be varied according to the ſituation and extent of the ground.

With reſpect to the ſituation; this muſt conſequently be immediately contiguous to the main houſe, whether high or low ſituated; remarking, however, that a ſomewhat elevated ſituation, or the ſide or ſummit of ſome very moderate riſing ground, is always the moſt eligible on which to erect the chief habitation, arranging the Pleaſure-garden accordingly; ſuch an expoſure being the moſt deſirable, both for the beauty of the proſpect, and healthfulneſs of the air; a low level ſituation, neither affording due proſpect of the garden, nor adjacent country, beſides being liable to unwholeſome dampneſs, and ſometimes inundation in winter: there are, however, many level ſituations, forming plains or flats, that poſſeſs great advantages both of ſoil and proſpect, and the beauties of water, without too copious moiſture; there are alſo ſometimes large tracts of ground, conſiſting both of low and high ſituations, as level plains, hollows, eminences, and declivities, and other inequalities, which may be ſo improved, as to make a moſt deſirable ſpot for a Pleaſure-garden, as the ſcene may be varied in the moſt beautiful manner imaginable. However, the choice of ſituation and ſcope of ground is not always attainable, ſo every one will regulate his plan in the moſt commodious manner poſſible, agreeable to the above hints.

The extent of a Pleaſure-Ground may be

various, according to that of the eſtate or premiſes, and of the quality and fortune, &c. of the owner; ſo may be from even a quarter or half an acre, to thirty or forty or more.

The ground ſhould previouſly be fenced, which may be occaſionally a wall, paling, or hedge, or ſome of each ſort, as may be convenient, and in ſome parts a foſſe or ha-ha, where neceſſary to extend the proſpect, either at the termination of a lawn, walk, or avenue; obſerving, the cloſe fences ſhould generally be concealed within ſide, particularly the wall and paling fences, by a range of cloſe plantation, unleſs where the wall may be wanted for the culture of wall-fruit. But ſometimes when a Pleaſure-ground adjoins to a fine park, paddock, or any agreeable proſpect, the boundary fence on that ſide is often either a low hedge, or a ha ha; but many preſer the latter, eſpecially at the termination of any ſpacious open, both to extend the proſpect more effectually, and give the garden an air of greater extent than it really has, at a diſtance, the ha-ha being ſunk, nothing like a fence appears, ſo that the adjacent park, fields, &c. appear to be connected with the garden. See WALLS, HEDGES, FOSSE, &c.

But with reſpect to the arrangement of the ſeveral diviſions, the following general ſketches are on a ſuppoſition of a conſiderable tract of ground; and if the plat of ground is ſmall, a greater ſimplicity of deſign muſt be obſerved in proportion.

Firſt, a noble open lawn of graſs ground, is extended on one of the principal fronts of the manſion or main houſe, directed either towards the open fields, park, or adjacent country, or towards the garden, if the ſituation requires it; or may be extended a little more or leſs each way, according as the ſituation and extent of ground may admit, or require; but, if poſſible, always conſiderably the moſt extenſive on the principal front; and ſhould be conſiderably wider than the houſe, if poſſible, and twice as long as broad at leaſt; or if the ſcope of ground admits it, may even be extended in length, as far as the extreme boundary of the garden: or carried over ha-ha's, to the adjacent park or paſture-grounds, &c. widening gradually in irregular windings, from the houſe outward; having each ſide bounded by various plantations of trees, ſhrubs, and flowers; in groves, clumps, thickets, and other elegant compartments, exhibited in a variety of rural forms, by various irregular, concave, and convex curves, and projections, to break all appearance of too ſtiff uniformity; introducing alſo between the plantations at intervals, breaks, or opens, of graſs-ground, communicating with the lawn and internal diviſions, in ſome places widely ſpread, in others more contracted; leaving alſo tracts for ſerpentine gravel-walks, winding under the ſhade of the plantations, ſo conducted as to command views of the lawn, and the interior diviſions occaſionally; obſerving, the homeward part of the plantation ſhould be inclined a little toward each wing of the houſe that company may ſooner arrive in the walks of the ſhrubbery; wilderneſs and groves, under the ſhade and ſhelter of the trees; but the outward extenſion on each boundary ſhould widen gradually towards the extreme termination, to give an air of grandeur, and admit of a full proſpect from and to the manſion. Each boundary being planted with a choice variety of ornamental trees and ſhrubs, deciduous, and ever-greens, arranged principally in ſeparate clumps, and other compartments, alternately, ſome conſiſting wholly of lofty trees, arranged ſometimes in regular groves, and ſome in groups or clumps, irregularly; other compartments being entirely of the ſhrub kind; and others conſiſting of trees, ſhrubs, and herbaceous perennials together: in all of which, arranging the taller growth backward, and the lower forward, according to their gradation of height; embelliſhing the fronts with the more curious low flowering ſhrubs and ever-greens, interſperſed with various herbaceous flowering perennials, all open to the lawn; and the termination of the lawn at the fartheſt extremity, if extended conſiderable outward to ſome agreeable proſpect, is generally continued open the whole width, by ſinking a ha-ha at the limits of the garden, to unite the view with the adjacent paſtures, plantations, and the open country, as well as admit of a grand view to and from the manſion. See LAWN.

But ſometimes the termination of the lawn, in default of proſpect beyond the limits of the garden, or that it is neceſſary to conceal the garden from the view of perſons without, is by a plantation of ſtately trees, in conſiderable concave, and convex ſweeps. Or ſmall lawns that extend immediately towards the garden, may be terminated by elegant ſhrubbery clumps, continued to the interior diviſion. However, for conſiderable lawns,

lawns, extended outward to the utmoſt verge of the garden, that admit of any tolerable proſpect of the adjacent fields, &c. a foſſe or ha-ha termination, is the moſt eligible, in order to continue the proſpect. See FOSSE and LAWN.

From the boundary plantation of the lawn, is continued the internal works, in a great variety of rural diviſions, in ſpacious walks and open ſpaces, bounded by ſhrubbery clumps, wilderneſs plantations, groves, thickets, &c. all in various elegant, irregular, compartments, as before mentioned, to exhibit a grand rural imitation, diverſified in a variety of forms.

In the general arrangement, the great art is to vary the proſpect of the different diviſions, ſo as they may variouſly preſent an air of novelty, and ſource of convenience and entertainment.

Around towards the outer boundary fence, is generally arranged a plantation of trees, and ſhrubs, in various irregular windings and projections next the garden, and broad enough to admit of a ſerpentine gravel-walk, winding through it all round the garden, under cover of the trees and ſhrubs, for private and ſhady walking: varying the plantation in different degrees of thicket and openings occaſionally, with here and there breaks and openings, for proſpect from the walks to the different parts of the garden and open country; and with circular or concave graſs ſpaces, bordering the walk at intervals for diverſity, and as places for ſeats, &c. under ſhade of the plantation.

In the more interior parts are exhibited magnificent walks, avenues, and graſs openings, ſome nearly ſtraight, others more or leſs winding, arranging in different directions; and having each ſide embelliſhed with plantations, in ſhrubbery clumps, groves of trees, wilderneſs plantations, thickets, and flower compartments, diſtributed in various arrangments and diſtances, admitting intervals of graſs ground ſurrounding and communicating with the various plantation diviſions, in ſome places of conſiderable extent, in others more or leſs contracted, according to the diſtance and arrangement of the ſeveral clumps and other compartments of plantation, which ſhould be exhibited in a variety of windings, openings, and cloſings, from one degree of light and ſhade to another; introducing alſo grand openings, at intervals, between the principal diſtricts of plantation, for views or proſpect, &c. and from the main walks and openings, have other ſmaller walks branching off at due diſtances, in a winding direction, to places of ſhade and retirement, amidſt the plantation, and for communication from one diviſion to another; exhibiting alſo opens of different figures and dimenſions, ſurrounded by clumps of trees and ſhrubs, ſerving ſome for receſſes, and places of ſhade, aforeſaid, others for garden edifices, as temples, grottos, rural ſeats, ſtatues, &c. and ſometimes for pieces of water; and if water from ſome upper ſpring or head, can be led in a winding courſe, through the lower parts in gentle meanders, it will have a charming effect; Other internal diviſions appear with an air of grandeur and magnificence, by exhibiting a ſpacious opening of graſs ground, bounded by the nobleſt trees and ſhrubs, in various elegant clumps, groves, groupes, and ſtraight ranges; and the opening terminated by ſome fine open proſpect, noble pieces of water or an ornamental building; and with gravel-walks, winding through the boundary plantations. Another part ſhall appear more gay and ſprightly, diſplaying an elegant flower-ground, deſigned ſomewhat in the parterre way, in various beds, borders, and other compartments, furniſhed with the moſt curious flowers; and the boundary decorated with an arrangement of various clumps, of the moſt beautiful flowering ſhrubs, and lively ever-greens, each clump alſo bordered with a variety of the herbaceous flowery tribe.

Another diviſion ſometimes preſents a wilderneſs, in irregular partitions of plantation, having many intervening ſerpentine walks, both private and open, bending in various directions, by many winding mazes or labyrinths, into openings formed in different parts amidſt the plantation, and to a grand one in the center of all; the boundary plantations of this diviſion being generally in cloſe aſſemblage, with tracts of ſerpentine walks between, leading in private meanders towards the interior parts; breaking out ſometimes into other walks that are open and ſpacious, both of graſs and gravel occaſionally, conducted alſo in ſerpentine turns, to cauſe the greater variety, having each ſide bordered with plantations of trees and ſhrubs, the talleſt behind, the lower growth in front; and from theſe grand walks, others more narrow and cloſe, branch off at intervals, in various windings, in ſome places being

ing closely bordered with tall trees, to effect a gloominess and perfect shade; the different walks leading now and then into circular openings of grass in different parts, each being surrounded with plantations as aforesaid; making also the principal walks terminate in a grand opening in the centre of the wilderness, in which may be some ornamental edifice, or fine piece of water, &c. furnishing all the plantation compartments, with a good variety of trees and shrubs; the deciduous and ever-green kinds principally in separate clumps, or quarters, interspersed with various wood flowers promiscuously, placing the more curious kinds of shrubs and flowers towards the fronts next the walks and openings, conspicuous to view. See WILDERNESS.

Straight ranges of the most stately trees, are sometimes arranged on grass ground in different parts, in contrast with irregular plantations; and produce a most agreeable effect, which though prohibited in many modern designs, always exhibit an air of grandeur; being arranged sometimes in single rows, others double, or two ranges at certain distances, forming a grand walk or avenue; in other parts, several ranges together in the manner of groves: all of which being arranged on grass ground occasionally in different situation, will have a grand and solemn appearance. See AVENUE and GROVES.

Sometimes an outward division discovers a close plantation of trees, like a thicket of woodland, arranged in irregular assemblage, mostly close and gloomy, resembling the internal arrangement of a wood; sometimes exhibiting sudden transitions of light and shade, by openings and closings, having serpentine walks winding through every part, and sometimes leading to openings in the midst of the plantation. Others breaking out suddenly from the thicket into open prospects of the other divisions; having all the walks bordered with flowering shrubs, hardy climbers, and various wood flowers that prosper under shade, and many common hardy shrubs, and herbaceous plants scattered promiscuously among the trees, to form more or less thicket, and cause diversity in the manner of a natural wood.

In other parts are sometimes discovered eminences, or rising grounds, as an high terrace, mount, steep, declivity, or other elevated situation, having the sides covered with grass and compartments of plantation; and walks leading under the shade of trees by easy ascents, to the top, where is presented an extensive prospect of the adjacent fields, cottages, hamlets, and country around, as well as afford a fresh and cooling air in summer.

Regular compartments and figures, in various forms, are also sometimes introduced in some extensive grounds, for variety, in contrast with the irregular works, and still to preserve some appearance of the remains of ancient gardening; such as straight walks, verged with borders of flowers, &c. regular parterres, in flower borders; square spaces, circles, and octagons, &c. inclosed with clipped hedges: hedge-work, formed into various architectural devices; detached yews, and other ever-greens, formed into pyramids and other regular figures; regular grass slopes, formed on the side of some declivity or rising ground. Bosquets of trees, surrounded with low ever-green hedges; straight avenues of trees in ranges, regular terraces, &c. a little of each being judiciously disposed in different situations, may prove an agreeable variety, by diversifying the scene, in contrast with the rural work aforesaid.

Sometimes a bleak declivity, or some rough hollow ground or vale, is made to exhibit a wild or uncultivated scene, by arranging some scattered clumps of trees, in the most irregular assemblage; the intervals or spaces between being rough grass ground, and here and there tufts of shrubby bushes, with sometimes a gentle rill of water, winding along the bottom of the declivity, or twisting its course through the vale.

Towards the lower parts of the garden, pieces of water are always exhibited where possible, in the most conspicuous points of view contiguous to the termination of the main lawn, or other spacious open, representing sometimes a bason, lake, &c. and sometimes a natural river, winding its course through different divisions, and its termination concealed by a curious turn, making it appear to lose itself in the adjacent plantations. See WATER.

With respect to the walks, these may be both of gravel, sand, and grass, but principally gravel for common walking; and grass for occasional walking in the heat of summer, which in dry hot weather may be more agreeable than the hard gravel-walks: therefore some of each sort is proper both for convenience and variety.

Gravel-

Gravel-walks, however, ſhould lead all round the garden and into the principal internal diviſions, ſo as to have dry and firm walking at all times of the year; when the graſs is too damp, as in winter and all wet weather.

Theſe gravel-walks ſhould be of proportional width, in different parts, according to the extent of the garden.

As to the diſtribution of gravel walks:—firſt a magnificent one, from fifteen to twenty or thirty feet wide, ſhould range immediately cloſe and parallel with the front of the houſe, and be conducted directly acroſs the lawn into the neareſt ſhrubbery and general plantation; where each ſide being verged with ſpaces of graſs ground, and ſhrubbery clumps, &c. from this main gravel-walk, other ſmaller ones, from five to ten or twelve feet wide, ſhould branch off at proper intervals, directed in the ſerpentine way; ſome leading through the outer boundary plantation, as already hinted; others into the central diviſions; and others carried along the boundary plantation of the main lawn; all of which walks being conducted through and between the different principal plantation, is highly requiſite, both for the convenience of ſhade, and retirement occaſionally, as well as to enjoy the variety of the different ſorts of trees, ſhrubs, and flowers, variouſly preſenting themſelves at different turnings: for the walks having various irregular twiſtings and windings, diſcovering only a moderate length at once, every turning produces new varieties; and ſhould likewiſe be ſo contrived, as at proper intervals to diſcover openings for proſpect into different principal diviſions of the garden; having in ſome places the plantation of trees, ſhrubs, and flowers, bordering cloſe upon the walks; in other parts, have on one ſide of the walks conſiderable graſs ſpaces, running into the adjacent plantation, in one or more concave curves, to form the greater diverſity.

And in ſome places the windings of the walks ſhould be gradual and moderate; in others exhibit ſudden turns, and grand ſweeps, each turning exhibiting ſometimes a magnificent projection in the plantation, others ſome ſpacious opening, bordered with curious plants; other parts a cloſe thicket, which ſometimes may ſeem to terminate the walk, when by a ſudden turn it breaks out all at once into ſome grand open diviſion, ſpacious open walk, an avenue, or elegant piece of water, open grove, &c. And in other parts a walk ſometimes ſuddenly divides into two or three diviſions, leading different ways, in bold ſweeps, each ſeparation being formed by a projecting clump of ſhrubbery work, or group of trees, &c. and each diviſion of the walk is conducted by curious ſerpentine turns, as ſoon to be concealed from the other; by the intervening plantation compartments.

All theſe gravel-walks ſhould be laid with the beſt gravel, ſix or eight inches deep at leaſt; but if more the better. See GRAVEL and GRAVEL-WALKS.

Graſs-walks may be conſidered as all the open graſs ſpaces, whether formed in the manner of walks, or as breaks or diviſions between the various plantations, all of which ſerving both for communication to different parts, and to render the ground more rurally ornamental, and for occaſional walking in dry weather in ſummer; but ſome tracts of conſiderable width and length, formed into graſs-walks, leading to different diviſions, having each ſide bounded with clumps of trees, ſhrubs, and flowers, gives an air of grandeur to the garden, allotting ſmaller breaks, or open of graſs, branching off between, the plantation compartments, as formerly mentioned.

The graſs ground of this garden may be formed, either by ſowing graſs-ſeed, or by laying it with turf, cut from ſome common or downs; but in very extenſive works turfing the whole would be a great expence; therefore ſeed is the moſt eligible for the principal ſpaces in very large gardens. For the method however of forming graſs-ground, both by ſeed and turfing, and for keeping the graſs in order, ſee GRASS.

Water being ſo ornamental in all garden deſigns, no pains ſhould be ſpared to introduce it where poſſible; but where it admits of a conſtant running ſtream, from ſome adjacent upper ſpring, its beauties may be rendered admirably fine, as it may be conducted in meanders through the garden; ſo as to effect a beautiful aſſemblage of verdure and water together; and if it ſhould be continued to any conſiderable length, one or more ornamental Chineſe bridges may be carried over at convenient places, which will have a beautiful effect, and ſerve for communication with the oppoſite diviſions, on each ſide of the rivulet.

Caſcades, and other water-falls, have alſo a fine effect, where there are a conſtant plentiful ſtream, and the ſituation proper to give

the water a due fall, from a high to a lower part, upon a parcel of rugged ſtones, to encreaſe the noiſe, and break and diſperſe the water.

In ſome grounds, by their natural ſituation, water may be obtained at a moderate expence; as ſometimes a contiguous vale, or meadow, bounded by riſing ground, and with a brook or rivulet conſtantly running through it, may be eaſily thrown into the moſt agreeable form: and ſometimes large ſprings iſſuing from an upper ground, and running down a moderate deſcent between two riſing grounds, to ſome vale below; it may be contrived, by making proper heads at diſtances, to form ſeveral lakes ſtrung together, as it were, one above another, up to the beginning of the ſpring; each head may form a beautiful water-fall, or caſcade; having the riſing grounds on each ſide embelliſhed with clumps of plantation.

Lakes and artificial rivers may alſo be contrived in a flat or level ground, where there are any contiguous brooks that can be conducted to ſupply them with water.

All pieces of water ſhould generally be contrived in a natural imitation, as much as the ſituation will admit; and its boundary on all ſides ſhould be graſs ground to ſome conſiderable width, ſloped off as eaſy as poſſible, correſponding with the other adjacent graſs ground, to admit of a proſpect of the water at ſome diſtance. See WATER.

The various compartments of ground intended for the different plantations, ſhould be digged or trenched for the reception of the plants; particularly for all plantations of ſhrubbery, wilderneſs quarters, flower compartments, &c. and the ground ſhould be raiſed ſomewhat above the common level, in a gentle ſwell; eſpecially all detached compartments; ſuch as ſhrubbery clumps, and flower partitions, and moſt other detached compartments of ground for any kind of ornamental plantation in gardens, ſhould generally be raiſed in a moderate rounding ſwell, gradually from each ſide to the middle; or for any continued ſide plantation it may be raiſed in a gentle ſlope: for the ſwelling and ſloping figure always ſtrikes the eye the moſt agreeably, as well as ſhew the plants to the beſt advantage.

But where intended to have groves of ſtately trees, or any ſtraight ranges of trees, either ſingly, or double lines, forming a walk or avenue; it is moſt in character to diſpoſe them all on graſs ground; in which they will appear the moſt rural and beautiful.

Likewiſe elegant ornamental trees, both as ſingle ſtandards, and in detached groups, or clumps, appear the moſt beautiful when diſpoſed on openings of graſs ground.

However, for all kinds of ſhrubbery and wilderneſs plantations, &c. the compartments ſhould generally be dug ground, as before obſerved.

All the plantation compartments of ſhrubbery, wilderneſs, &c. ſhould be planted with ſome conſiderable variety of different ſorts of trees, ſhrubs, and flowers, artfully diſpoſed in irregular arrangement; the taller behind, the loweſt forward, and the different ſorts ſo intermixed, as to diſplay a beautiful diverſity of foliage and flowers, diſpoſing the more curious kinds contiguous to the principal walks and lawns.

For a liſt of the different ſorts of trees, ſhrubs, &c. proper for embelliſhing the ſeveral diviſions, See DECIDUOUS TREES, and EVERGREENS.

Obſerving, that as the trees and ſhrubs are of two different tribes, deciduous, and evergreen kinds; thoſe of each tribe ſhould be moſtly planted in ſeparate clumps, in which they will effect the moſt agreeable variety; and in ſome places may exhibit clumps compoſed of both ſorts, to cauſe the greater diverſity; and many of the moſt conſpicuous deciduous compartments may be embelliſhed towards the fronts, with ſome ſhowy evergreens thinly diſperſed; which will appear ornamental and lively in winter, when the deciduous plants are deſtitute of leaves. In planting the ſeveral ſhrubbery clumps, &c. ſome may be entirely of trees; but the greater part an aſſemblage of trees and ſhrubs together; ſome entirely of the low ſhrub kind, in different ſituations, between the clumps, of larger growth; likewiſe ſhould interſperſe moſt of the ſhrubbery and wilderneſs compartments with a variety of hardy herbaceous flowery plants, of different growths; having alſo here and there clumps entirely of herbaceous perennials: the diſtribution or arrangement of the clumps, and other diviſions of the different kinds, both trees, ſhrubs, and flowers, ſhould be ſo diverſly, as to exhibit a proper contraſt, and a curious variation of the general ſcene.

And in the diſpoſing the various trees, ſhrubs, and other plants in their reſpective compartments, obſerve, ſomewhat in the quincunx way, not exactly ſo, nor in regular ranges; and for the moſt part, place the talleſt

talleſt towards the middle or back part, and the lower forward towards the front, according to their natural ſtature of growth; obſerving alſo to intermix the different ſorts in each clump, &c. in ſuch order, as to diſplay a diverſity of different foliage and flowers, as aforeſaid, as well as exhibit a conſpicuous variety. Likewiſe placing the various ſorts at ſuch proportionable diſtances and diſpoſitions, according to their various growths as each may have full ſcope to ſpread its head; and ſo as the proſpect of one may be no interruption or impediment to the growth and appearance of another, but all ſo judiciouſly arranged as to ſet off each other and appear to proper advantage from the contiguous lawns, walks, and other diviſions. See PLANTATION.

Obſerve, in planting any continued or running plantation where ſhady walks are deſigned, that particular care is requiſite in arranging a due ſhare of the taller trees and ſhrubs nearer the walks and in ſuch order as to produce the deſired effect, particularly in the continued plantation of ſhrubbery work around the outward boundary, and on the boundary of the lawn and other running plantations, through which ſerpentine walks are carried: planting many tall-growing trees and ſhrubs more or leſs towards the walk in ſuch arrangement as to produce proper ſhade, ſhelter, and private walking, with occaſional openings and cloſings at intervals, as hath been already obſerved; interſperſing alſo many ſmaller ſhrubs and hardy herbaceous plants between the larger growths; diſpoſing the whole ſo judiciouſly as to afford alſo a ſource of variety in the excurſion of the walks.

Theſe plantations for ſhady walks are highly neceſſary to retire to occaſionally, for ſhelter from the injuries of the weather: they afford ſhade from the ſcorching rays of the ſummer's ſun, ſhelter from tempeſtuous winds and cold blaſts, and for private walking when required. But where very cloſe and gloomy ſhade is required in any particular parts for diverſity, ſome tall trees ſhould be arranged cloſe along the verge of the walks backed with others, and a variety of hardy ſhrubs, in ſuch order as to produce the proper effect.

In planting groves and avenues, they ſhould be compoſed principally of the tree kind, and ſuch as are of ſtraight and handſome growth, with the moſt branchy, full, regular heads, and may be both of the deciduous and ever-green tribe; but generally arranged ſeparately; which, for groves and avenues, ſhould always be in ſome conſiderable open ſpace, formed into graſs ground, either before or after planting the trees; and in planting the groves, it is moſt eligible to arrange the trees in lines, in ſome places ſtraight rows, others in gentle bendings, or eaſy ſweeps, having the rows at ſome conſiderable diſtance that the trees may have full ſcope to diſplay their branchy heads regularly around; and in ſome places may have cloſe groves to form a more perfect ſhade. And as to avenues and walks of trees; they may be formed either entirely of deciduous trees, or of ever-greens; but the deciduous kinds are in moſt eſtimation for forming fine avenues: however, avenues and grand graſs-walks, planted with beautiful ever-green trees, make a fine appearance. In both ſorts, the trees are moſt commonly diſpoſed in ſtraight rows, one on each ſide of the avenue, though ſometimes grand walks of trees may be both in ſtraight lines and in windings, to exhibit the greater variety, planting the trees generally, both in the avenues and walks, at proper diſtances to have full ſcope to branch out regularly around and diſplay their beautiful heads. See AVENUES, GROVES, &c.

But thickets may be compoſed of all ſorts of hardy deciduous trees, planted cloſe and promiſcuouſly, and with various common ſhrubs diſperſed between the trees, as underwoods, to exhibit a more or leſs thicket occaſionally in different parts. See THICKET.

Thickets may alſo be of ever-green trees, particularly of the pine and fir kinds.

Straight rows of beautiful ever-greens, as pines, firs, cypreſs, cedars, &c. forming magnificent walks, are very ornamental.

In ſome open ſpaces of graſs-ground, ſuch as ſpacious open lawns, or other conſiderable opens in parks, &c. ſhould diſpoſe ſome of the moſt beautiful trees and elegant ſhrubs detached, both ſeparately as ſtandards or ſingle objects; and in groups or aſſemblages, from two or three to five or ten or more in different groups or clumps; ſome irregularly, others in curves, ſtraight lines, &c. for variety, arranging both ſingle ſtandards, and groups a conſiderable way aſunder not to obſtruct the proſpect, and at ſuch irregular diſtances as if they had grown there by chance.

It ſometimes happens that on the ſpot or tract of ground which is deſigned for a Plea-

ſure-ground are found large old trees of conſiderable ſtanding, properly ſituated to be introduced into the deſign, ſometimes in proper aſſemblage for conſtituting a grove or a thicket, and ſome as ſingle ſtandards, groupes, or clumps, &c. which will prove a conſiderable advantage; and ſhould be preſerved with the utmoſt care, as it would probably require an age or two to form the like with young plantations; and although the trees ſhould ſtand ever ſo cloſe, or irregular and ſtraggling, they, with proper addreſs of thinning or regulating where neceſſary, may be introduced for purpoſes as above ſo as to have a fine effect. See GROVES, &c.

A commodious ſpace for a flower-ground diſtinct from the other diviſions as formerly hinted, is moſt neceſſary for the culture of the more curious and valuable kinds of flowers.

This principal flower-ground forming a diſtinct diviſion, excluſive of the other flower compartments diſtributed in different parts in contraſt with the ſhrubbery clumps, &c. ſhould be allotted for a choice collection of the fineſt kinds of both bulbous and fibrous rooted flowers. The form of this ground may be either ſquare, oblong, or ſomewhat circular; having the boundary of the diviſion formed by an arrangement of a curious ſhrubbery embelliſhed with a collection of the moſt beautiful flowering ſhrubs; and the interior part ſhould be divided into many narrow compartments, either in the manner of a parterre, formed into ſtraight borders, beds, &c. edged with box, ſee PARTERRE; or divided into plain four-feet-wide beds arranging parallel, having two-feet-wide alleys between bed and bed: in either method having a walk carried all round next the outer boundary, then a border ſurrounding the whole diviſion, and within this have the various diviſion of beds, &c. as above, raiſing them all in a rounding manner, higheſt in the middle, and edge the compartments principally with dwarf-box, and ſome with thriſt and pinks by way of variety, laying the walks and alleys with the fineſt gravel.

In this diviſion you ſhould depoſite all your fineſt hyacinths, tulips, narciſſus, polyanthos-narciſſus, jonquils, ranunculus, anemonies, and all the other more curious bulbous and tuberous rooted flowers; each ſort principally in ſeparate compartments, eſpecially of the choicer kinds; which being neceſſary both for diſtinctions ſake and for the convenience of giving them occaſional protection from inclement weather: but for particulars, in reſpect to the ſorts, method of planting, and general culture, ſee the reſpective articles under the proper *genera*.

Likewiſe in this diviſion ſhould be planted a curious collection of the fineſt fibrous-rooted flowery plants, as carnations, polyanthuſes, auriculas, and many other curious ſorts, arranging ſome of the moſt valuable in beds ſeparately: others may be diſperſed in different compartments forming an aſſemblage of various ſorts.

In other compartments may exhibit a variety of all ſorts, both bulbous and fibrous-rooted kinds.

In ſpacious Pleaſure-grounds, various buildings and erections are introduced as ornaments to particular departments. For inſtance, light ornamental buildings, as temples, a banquetting-houſe, bowers, alcoves, grottos, rural ſeats, cottages, fountains, obeliſks, ſtatues, and other edifices and devices, are often introduced in different parts in openings between and contiguous to the diviſions of plantation and termination of grand walks, &c. Some of theſe kinds of ornaments however being expenſive, are rather ſparingly introduced; ſometimes a temple is preſented at the termination of a grand walk or opening, or ſometimes a temple, banquetting-houſe, or bower is ſtationed in the centre of ſome ſpacious opening of graſs ground in the internal diviſions; other parts preſent alcoves, bowers, grottos, rural ſeats, &c. at the termination of different walks or openings and with rural ſeats placed in different opens or breaks by the ſides of long walks, under ſhade of trees, for places of reſt, &c. [Fountains and ſtatues are generally introduced in the middle of ſpacious opens; ſtatues are alſo often ſtationed at the termination of particular walks; ſometimes in woods, thickets, and receſſes, upon mounts, terraces, and other ſtations, according to what they are to repreſent.

Sometimes alſo there are exhibited root-houſes, rock and ſhell-work, &c. repreſenting hermitages, caves, and the like; being generally ſtationed in ſome retired or private ſituation, and as theſe kind of buildings being arched or vaulted, they are commonly covered with a coat of earth and turfed with graſs, ſo as to appear like a ſort of mount, hillock, or knoll, and planted with ſome little

little clumps of ſhrubs, &c. having private walks leading to the entrance.

Likewiſe in ſome parts is exhibited artificial rock-work, ſometimes contiguous to ſome grotto, fountain, rural piece of water, &c. and planted with a variety of ſaxatile plants, or ſuch as grow naturally on rocks and mountains.

Ornamental bridges over artificial rivers, or any rural pieces of water in ſome magnificent opening, ſo as to admit of a proſpect thereof at ſome diſtance or from the habitation, have a fine effect.

*General Culture of the Ground.*

With reſpect to the general culture of this ground, neatneſs muſt be ever obſerved in every part; the walks, lawns, ſhrubbery, clumps, &c. and the ſeveral compartments of trees, ſhrubs, and flowers, kept duly furniſhed with a proper ſtock of the various plants.

The gravel-walks muſt always be kept free from weeds and all ſorts of litter, and ſhould be rolled twice or three times a week in ſummer, particularly the principal walks, but never leſs than once a week; previouſly trim the edges cloſe when neceſſary, eſpecially if verged with graſs-ground; pulling out all weeds, and lightly ſweeping off all looſe litter: and then roll them well with an iron or ſtone roller. The rolling in ſummer ſhould be occaſionally performed immediately after ſhowers of rain, particularly the firſt after any continuance of very dry weather, to ſettle all the looſe parts compact and ſmooth: in winter, the rolling ſhould alſo be occaſionally performed; obſerving, it is improper to break up the walks in that ſeaſon in rough ridges as often practiſed, to remain in that unſightly manner till ſpring, whereby the walks are rendered uſeleſs at a time when there is hardly any dry or ſound walking upon graſs or other parts, beſides their having a diſagreeable ſlovingly appearance; let the walks therefore remain undiſturbed, at leaſt till ſpring, when, if the ſurface is foul, or moſſy, they may be broken up, and turned the ſurface to the bottom, and the bottom to the top; directly tread, rake, and roll them ſmooth, proper for walking on. See GRAVEL WALKS.

All the principal graſs lawns and walks within the limits of the Pleaſure-garden ſhould alſo be kept perfectly neat by frequent mowing in ſummer, to keep the graſs ſhort, cloſe, and fine, like a fine paſture down or common; likewiſe poleing it frequently with a long pole to ſcatter the worm-caſts of earth which ſo greatly deface all graſs; and give alſo occaſional rolling both to clean up the ſcattered worm-caſts to make the ſurface clean, and to render it firm and ſmooth. The poleing and rolling ſhould generally be performed the day previous to mowing, whereby the mowing will be more eaſily, expeditiouſly, and effectually performed; obſerving the mowing will be neceſſary about once a week or fortnight, from March or April until September or October, chooſing always dewy mornings, or moiſt weather for this work, being careful to have each mowing performed with an even hand, not to ſcore or leave the mark of the ſcythe at each ſtroke, which has a moſt diſagreeable appearance; and directly after mowing ſweep up all the ſwarths of graſs as clean as poſſible into heaps and carry them away, See GRASS.

Where numerous wild daiſies deface the graſs in May or June as is ſometimes the caſe, even often in a day after mowing, they may headed down at a great rate with an old broad ſword fixed in the end of a long pole.

Likewiſe keep all graſs-ground clean from litter, ſuch as fallen leaves of trees, &c. which may be expeditiouſly effected by a light broom or beſom on a long handle. See BROOMS.

The edges of all principal graſs-walks and thoſe of graſs-ground, next gravel-walks in particular, ſhould always be kept cloſe and even; which once a year in ſpring, when the walks are to be turned and new laid, may be previouſly cut even ſlightly with an edging iron: after this, during the ſummer, they may be trimmed even occaſionally as the graſs grows, either with the points of the garden-ſhears, with a pair of ſheep-ſhears, or with the point of a knife; for if theſe edges are not kept cloſe and even they have a ſlovenly appearance.

The ſhrubbery and other plantations of trees and ſhrubs, ſhould generally all be ſuffered to take their own natural growth, and branch out into full heads, only juſt giving a little occaſional trimming to any very irregular growths, ſuch as retrenching or reducing any very luxuriant rude ſhoots, or conſiderable ramblers, running wildly from all the other branches and all dead wood; likewiſe, for the general part, keep all the ſhrubs from interfering or intangling with one another, by ſhortening occaſionally any

ſtraggling or rambling interfering branches, ſo as the head of each ſhrub may appear diſtinct, in which they will ſhew themſelves to proper advantage, and effect a more agreeable variety.

Obſerving, the beſt ſeaſon for performing thoſe occaſional regulations of pruning is, for the deciduous kinds, any time in winter or ſpring when deſtitute of leaves, eſpecially for any general trimming; but for the ever-green kinds, the moſt eligible ſeaſon to give any neceſſary pruning, is either autumn or in ſpring, about March or April, eſpecially when any conſiderable trimming may be occaſionally required, as if performed in winter or very ſharp weather, that by laying the more interior tender parts more immediately open to the cold, it often injures the leaves and young ſhoots; however, where only a little retrenching or ſhortening here and there a rambling ſhoot is neceſſary, it may be performed almoſt any time to any of the ſorts: but remarking both of the deciduous and ever-green kinds, that when any general trimming is occaſionally required throughout the different plantations, it is highly proper to perform it at the above-mentioned ſeaſons, previous to giving the annual digging to the ground between the ſhrubs, &c. as directed below.

When cloſe thickets however are intended, no regulation or thinning need be obſerved, but let the various ſorts run promiſcuouſly.

The ground of the ſhrubbery plantation and wilderneſs quarters ſhould generally be digged every year, in winter or ſpring; previouſly giving the ſhrubs any neceſſary trimming as above obſerved; then dig the ground between neatly, one ſpade deep, trimming off any rambling ſuckers or ſpawn from the roots, leaving the ſurface of the ground level and ſmooth: this operation gives health and vigour to the plants, kills weeds, and gives the place an air of culture, and a lively neat appearance.

After this general digging the clumps, &c. the ground muſt be kept clean from weeds all ſummer, by occaſional hoeing in dry weather, which with a Dutch ſcuffing-hoe, may be expeditiouſly performed. See HOE and HOEING.

Great care is requiſite to ſupport with ſticks all ſuch plants as require it, particularly all ſuch of the herbaceous tribe that are liable to be over-turned by the wind, weight of wet, &c. for there is great merit in preſerving all tall plants in an upright poſture.

Keep likewiſe all the flower compartments in neat order by an annual digging, in autumn, winter, or ſpring; hoeing in ſummer to deſtroy weeds; at each hoeing always rake the ſurface ſmooth, particularly the principal borders and other compartments: likewiſe according as the various plants grow up, let ſuch as need ſupport have ſticks placed to preſerve them upright; and as they have done flowering and their ſtalks decay, cut them down cloſe, clearing off alſo all decayed leaves, and other rubbiſh from time to time as they appear; taking up alſo the roots of curious bulbous flowers, as their leaves and ſtalks decay: and in autumn, about October or November, it is proper to give a general dreſſing by cutting down all remaining decayed ſtalks, and prepare to dig the ground: obſerving, if any manure is neceſſary, this is the time to apply it; ſo digging the ground neatly one ſpade deep, and then if any kinds of plants or roots are wanted, plant them now, and finiſh with a neat raking, that the whole may lie clean and decent during the winter; and in ſpring ſtir the ground a little with a hoe or rake, or ſuch as was not digged in autumn or winter, as above adviſed, muſt now be done; and finiſh putting in ſuch plants that were omitted in autumn; then rake the ground ſmooth that every part may aſſume a freſh chearful appearance in the ſpring and ſummer ſeaſons.

All kinds of hedge-work and trained figures of ever-greens, ſhould be ſhorn or clipped annually in ſummer with garden ſhears; but to keep them perfectly neat, twice every ſummer is neceſſary, the firſt in June, and the ſecond in Auguſt or September. See HEDGES.

Alſo all edgings of box, &c. to walks, borders, and beds, ſhould always be neatly clipped once or twice every year in ſummer; but to have them extremely neat, they ſhould be clipped twice in that ſeaſon, *i. e.* in May or early in June, and in Auguſt, chooſing principally moiſt weather, if poſſible, for if cut in very dry hot weather, the leaves change brown and unſightly: the ſame alſo happens if clipped in winter, or early in ſpring, while cold weather and froſty nights prevail, ſo ſhould cut theſe edgings principally in ſummer. See BUXUS, article *Dwarf-box for edgings.*

All

All other edgings of thrift, pinks, daiſies, London-pride, &c. ſhould alſo be kept cut in on each ſide, every ſummer after the flowers are paſt, to keep them neat, and within due bounds, performing it in moiſt weather, as obſerved of the box edgings; likewiſe edgings of underſhrubby aromatics muſt have the operation of clipping annually performed at ſides and top in ſummer: for all edgings ſhould be kept low, narrow, and regular, otherwiſe they will appear clumſey and unſightly. See EDGINGS.

For particulars relative to the general culture of the various ſhrubs and flowers, ſee their reſpective *genera*.

*Of ancient Deſigns.*

Deſigns in ancient gardening for a Pleaſure-ground conſulted uniformity in every part, exact levels, ſtraight lines, parallels, ſquares, angles, circles, geometrical figures, &c. all correſponding in the greateſt regularity, to effect an exact ſymmetry and proportion.

Straight walks were every where obſerved, and all arranged parallel, and croſſing one another in regular interſections; generally a grand one of gravel was extended in a ſtraight line immediately from the front of the main houſe, having each ſide verged either with a regular ſtraight border of earth, furniſhed with a variety of flowers, &c. and ſometimes having a verge of graſs three or four feet wide, then a border embelliſhed as above with various plants; this main walk being often interſected by others at regular diſtances, ſo as ſometimes to divide the ſpace immediately in the front of the houſe into four, ſix, or more equal ſquares, ſome of which were ſometimes formed into parterres, ſometimes only naked graſs-plats, or other uniform diviſions; and often the whole garden was thus divided by ſtraight, parallel, and interſecting walks into many regular ſquares and angles, without any variation.

Grand parterres were very commonly preſented immediately on the front of the main houſe, having a grand walk of graſs or gravel directly from the houſe through the middle, or dividing the parterre ground into two diviſions. See PARTERRE.

In the more interior parts, large tracts of ground were frequently divided by ſtraight graſs walks into many ſquare and angular diviſions of wilderneſs, each diviſion ſurrounded by tall regular hedges of various kinds of trees and ſhrubs, kept in uniform order by an annual ſheering or clipping; having the interior part of each quarter planted with trees and ſhrubs, which however were in a manner concealed by the hedges from perſons in the adjacent walks, ſo that hardly any thing but cloſe hedges, the ſame thing over again, appeared to view, on each ſide of the walks; and all the walks generally led into uniform openings of graſs, particularly to a grand circle or octagon in the centre.

Frequently there were partitions of regular hedge-work, particularly of ever-greens, ſurrounding large ſquares of graſs ground, deſigned as pieces of garden ornaments, being often formed into various uniform devices of rural architecture; ſuch as pilaſters, arcades or arches, porticoes, galleries, amphitheatres, pavilions, cabinets, bowers, pediments, niches, and cornices; likewiſe regular arbors, having the ſides formed into arcades, and ſometimes the top curiouſly vaulted; and with various other formal imitations, all performed in hedge-work, which were often ſo arranged and artfully trained, as to effect an air of grandeur and art, as well as afford an opportunity for the gardener to diſplay his ingenuity in ſuch kind of works. High hedges were alſo in great repute, as boundaries to grand walks and avenues, ſometimes carried up from fifteen or twenty, to thirty or forty feet high; ſometimes trained perfectly cloſe from the very bottom to top, others open below a conſiderable way, and curiouſly formed into regular arches, &c. all of which ſometimes appeared magnificent and ornamental, but were troubleſome and expenſive to keep in order, on account of their great height: however, all ſorts of hedge-work was generally eſteemed ſo ornamental in ancient gardening, that almoſt every diviſion was ſurrounded with regular hedges of one ſort or other, preſenting themſelves to view in every part, ſhutting out all other objects from ſight; but in modern deſigns hedges are rarely admitted; every compartment of plantation being left open to view from the walks and lawns, to have a full proſpect of the various trees, ſhrubs, and flowers, which conſequently are more beautiful than ranges of cloſe hedges: but for the ſake of variety, a little ornamental hedge-work might ſtill be introduced in ſome particular parts of the ground. See HEDGES, the article *Internal Hedges*.

Wilderneſſes were always deſigned with the greateſt uniformity, the ground being di-

vided

vided by walks into many ſquares and angles, all correſponding, and all the walks ſtraight, and the principal ones all leading to ſome common centre or opening, ſuch as a circle, octagon, &c. with all the quarters or diviſions commonly ſurrounded with cloſe hedges as before obſerved, both of the deciduous and ever-green kinds. See WILDERNESS.

Labyrinths of hedge-work, in the manner of a wilderneſs, alſo prevailed in many large gardens. See LABYRINTH.

Detached trained figures of ever-greens, as yew, cypreſs, juniper, holly, box, and various other cloſe-growing ever-green plants, but principally yew, were alſo very predominant in ancient deſigns, and generally diſpoſed in regular ranges along the borders and other verges of grand walks; being trained by clipping into various formal ſhapes, as pyramids, obeliſks, columns, &c. in a variety of forms, with a multitude of other formal figures, all placed in the moſt exact arrangement. Some alſo were often placed ſingly in the midſt of ſome circle, octagon, or other open ſpace, and were all kept in order by clipping once or twice every ſummer, and were conſidered as great ornaments.

Straight rows of the moſt beautiful trees forming long avenues and grand walks were in great eſtimation, which, though not often admitted in modern deſigns, were formerly conſidered as great ornaments, and no conſiderable eſtate and eminent Pleaſure-ground was without ſeveral of them; but modern planners rarely introduce ſtraight ranges of trees for avenues or walks, but even often demoliſh old ones of a century or two ſtanding, as being thought too formal; however, ranges of trees, forming ſpacious avenues, &c. about extenſive grounds, always give an air of grandeur and dignity to the premiſes.

Regular graſs ſlopes alſo greatly prevailed in moſt old gardens, as ornaments to particular diviſions; ſometimes was formed at the beginning of ſome riſing ground, alſo ſometimes at the termination, and frequently ſome low ground, canals, and other formal pieces of water, were bounded by a range of regular graſs ſlopes; likewiſe regular graſs ſlopes formed the ſides of terraces and other riſing grounds. Moderate graſs ſlopes alſo often formed a boundary to ſome open ſpaces, as a bowling-green, flower-garden, &c. forming a ſort of terrace all round, having ſometimes a gravel-walk at top; theſe ſlopes were always formed with the greateſt regularity and exactneſs, which in ſome ſituations were very ornamental. They were of various dimenſions in reſpect to height, from one foot to ten or twenty high, according to the nature of the ſituation and purpoſe they were deſigned for, in different parts; and ſome being ranged ſingly, others double, treble, or ſeveral one above another on the ſide of ſome conſiderable riſing ground, in a theatrical arrangement.

Regular terraces, either on a natural eminence or of forced ground, were alſo introduced for ornament, and for the ſake of proſpect, and of enjoying the freſh air in ſummer.

But as the above taſte in the ancient ſtyle of deſigning gardens, being generally crowded every where with exact uniform diviſions and formal figures, ſome of which being often trifling, and the ſame thing often prevailing in almoſt every part, that even gardens of very conſiderable extent afforded very little variety; and the perpetual ſhew of ſtiff formality of the ſame thing over again, together with the numerous ſurrounding hedges in every diviſion, obtruding conſtantly upon the ſight, obſtructing all other objects, that at laſt they became ſo diſagreeable to perſons of taſte, they aboliſhed almoſt all formal works from their gardens, ſuffering hardly any regular appearance, ſubſtituting rural works, in imitation of nature, as already deſcribed.

However, for the ſake of diverſity, ſome of the more elegant regular works might ſtill be admitted ſparingly, in particular diviſions, in contraſt with the general rural performances, ſo as in ſome places to exhibit a grand ſtraight gravel or graſs-walk, in others a parterre, and in ſome places ſtraight rows of the moſt beautiful trees, forming walks and avenues, and ſometimes a range of hedge-work, and here and there a pyramid of yew or other proper ever-greens; and ſometimes a regular graſs ſlope, formal terrace, &c. all of which, if judiciouſly diſpoſed, might aſſiſt in diverſifying the general ſcene.

PLENUS *Flos*, a full or moſt double flower; a flower having the greateſt plenitude or multiplicity of petals, often to the diminution or entire excluſion of the parts of fructification.

Perfectly Full Flowers, whoſe multiplicity of petals obliterate the generative organs, conſequently prove barren, *i. e.* rarely ever producing ſeed; but moſtly all Full Flowers are varieties of ſingles, which are always the original ſpecies; ſo that the ſingles and half-doubles only

only produce the ſeed, and from which both double and ſingle flowers are obtained; however, the full double flowers are eſteemed the moſt beautiful, and are often the floriſts pride.

But all flowers of the above luxuriant nature are commonly called double flowers; obſerve, however, a Full Flower is to be conſidered as the higheſt degree of luxuriance or plenitude, as the petals are generally multiplied in many ſeries to the very centre, ſo as frequently to choak up all the male and female organs, as ſometimes happens in carnations, ranunculus, anemonies, &c. a double flower, properly ſo called, may be ſaid to have its ſeries of petals only twice repeated; however, among gardeners and floriſts all multiplied flowers, whether their petals are repeated but twice, thrice, or many times, are commonly all denominated double flowers, and are generally in the greateſt eſtimation, as being the moſt delightful to the eye, in the opinion of floriſts.

But although full and double flowers are often the moſt beautiful to the eye, as juſt obſerved, yet they are to be conſidered as an unnatural increaſe and monſtrous production; by Linnæus called vegetable monſters, becauſe double flowers are only varieties of ſingles, varying by culture from their natural ſingle or *characteriſtic* ſtate; for the *characters* of the genera are always drawn from ſingle flowers, never from full or double ones, whoſe number of petals often vary more or leſs by culture, and are never to be depended on to eſtabliſh the *characters*.

Full or double flowers therefore are varieties both of monopetalous and polypetalous flowers; for example, the hyacinth, tuberoſe, primroſe, &c. being all monopetalous or of one petal only in their natural or *characteriſtic* ſtate, yet the increaſe or repetition of the petals one within another is often continued to the very centre, choaking up the organs of fructification; aforeſaid, though perfect fullneſs is leſs frequent in flowers with one petal than in thoſe with ſeveral. Polypetalous flowers therefore, ſuch as carnation, anemone, ranunculus, marſh-marigold, columbine, poppy, pœony, tulip, crown-imperial, &c. all having ſeveral petals, are liable to all degrees of luxuriance, from the loweſt to the greateſt fullneſs.

The mode of luxuriance is effected either by a multiplication of the diviſion of the limb or upper part of the petal, or of the petals entirely; and in flowers having nectariums, the impletion is often formed by a multiplication of the nectarium, as frequently occurs in columbine, narciſſus, larkſpur, &c.

Compound flowers are alſo liable to various degrees of luxuriance; as in African marigold, ſun-flower, garden-daiſy, feverfew, &c. for an account of the mode of impletion, ſee COMPOSITOS *flos*.

PLUMBAGO, Lead Wort.

This genus conſiſts of ſome flowery perennials, of which, one is herbaceous, for the open borders, and the others are ligneous, or underſhrubby plants, for the ſtove; have fibrous roots, ſending up ſlender ſtalks, three or four feet high, adorned with oval ſpear-ſhaped leaves, and terminated by cluſters and ſpikes of ſmall monopetalous flowers.

Claſs and order, *Pentandria Monogynia*.

*Characters.*] CALIX, is monophyllous, tubular, pentagonal, quinquedented, and permanent. COROLLA is monopetalous, funnel-ſhaped, divided above into five oval-ſpreading ſegments; and a nectarium of five very ſmall valves, including the germen. STAMINA, five ſubulated filaments ſitting on the nectarium, and ſmall verſatile antheræ. PISTILLUM, a very ſmall oval germen, ſimple ſtyle, having a ſlender five-pointed ſtigma. PERICARPIUM, none, a ſingle oval ſeed lodged in the permanent calix.

There are about four ſpecies, the principal of which are the three following.

*Hardy Herbaceous Kind.*

[1]PLUMBAGO *Europæa*.

*European Plumbago.*] Hath thick, fibrey, deſcending roots, ſending up many ſlender, channelled ſtems, branching a yard high; ſpear-ſhaped, rough, amplexicaule leaves, and all the ſtalks and branches terminated by bunches of blue flowers, in October.

*Varieties.*] With purple flowers — with white flowers.

They are all perennial in root, and annual in ſtalk; natives of Italy, &c. but ſucceed in the open ground.

*Ligneous Stove Kinds.*

Theſe are ſomewhat underſhrubby, and natives of India.

[2]PLUMBAGO *Zelanica*.

*Ceylon Plumbago.*] Hath a thick juicy, acrid root, ligneous, very ſlender, branchy ſtalks, riſing three or four feet high; oval, ſmooth, leaves, having ſhort foot-ſtalks; and the branches

branches terminated by ſpikes of white flowers, appearing great part of the year.

[3]PLUMBAGO *Roſea.*

*Roſe Plumbago.*] Hath ſlender ligneous ſtems, with gibbous or ſwelling joints; oval ſmooth leaves, having foot ſtalks; and all the branches terminated by ſpikes of red flowers, great part of the year.

All theſe plants merit culture, to encreaſe the variety of the flowery tribe; the firſt ſort for the pleaſure ground; and the other two to plant in pots, and place in the hot-houſe collection.

Their propagation is;

The firſt ſort, by parting the roots in autumn, when the ſtalks decay.

And the ſecond and third ſorts by ſeed, in a hot-bed, in the ſpring: they may alſo be tried by ſlips and cuttings, aſſiſted by artificial heat.

PLUMERIA, Red Jeſſamine.

The plants are woody, ſucculent, flowery exotics, of South America; retained here in our hot-houſe collections, for variety, riſing ſeveral feet high; ornamented with oval, oblong, and ſpear-ſhaped leaves, and beautiful monopetalous funnel-ſhaped five-parted flowers, terminating the branches in cluſters.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is ſmall, obtuſe, and five-parted. COROLLA, is monopetalous, infundibuliform, with a long tube, widening upwards, and the top divided into five oblong, oval, erect, ſpreading ſegments. STAMINA, five awl-ſhaped filaments, having connivent antheræ. PISTILLUM, an oblong, bifid, germen, ſcarce any ſtyle, but a double acute ſtigma. PERICARPIUM, two long, ventricoſe, acuminated, nutant, unilocular, and univalvular folliculi; having numerous oblong, imbricated ſeeds.

The ſpecies are;

[1]PLUMERIA *Rubra.*

*Red Plumeria.*] Riſes with a woody, thick, ſucculent, branching ſtem, eighteen or twenty feet high; large oval-oblong leaves, having ſhort, biglandular foot-ſtalks; and the branches terminated by cluſters of elegant, red, odoriferous flowers.

*Variety.*] With pale-red flowers.

[2]PLUMERIA *Alba.*

*White Plumeria.*] Riſes with a woody, thick, ſucculent, branchy ſtem, eight or ten feet high; ſpear-ſhaped, pointed, revolute leaves; and the branches terminated by cluſters of white odoriferous flowers, with the pedunculi having tuberoſe ſwellings above.

[3]PLUMERIA *Obtuſa.*

*Obtuſe Plumeria.*] Hath a woody, thick, ſucculent, branchy ſtem, riſing ten or twelve feet high; ſpear-ſhaped, ſhort, obtuſe leaves; and the branches terminated by cluſters of fragrant white flowers.

All theſe plants flower here in our ſtoves, in ſummer, about July and Auguſt, but never produce ſeeds in England.

They being all exotics of the hot parts of America, require the indulgence of a hot-houſe all the year in this country; and are retained here in many curious gardens, as plants of variety and ornament, for the beauty of their ſtems, leaves, and flowers, particularly the latter, which riſing in large cluſters, make a fine appearance, ſix weeks or two months in ſummer, and have great fragrance; but thoſe of the *Red Plumeria* are conſiderably the moſt beautiful.

All the three ſpecies are of a very ſucculent quality, both in ſtem, branches, and leaves; replete with a milky juice of a very cauſtic and poiſonous nature.

As being all of the above ſucculent temperature, and exotics from the hot parts of the world, they muſt be potted in light, dry, ſandy earth, and placed almoſt conſtantly in the ſtove; and ſupplied with proper waterings, which, however, as being ſucculents, muſt be applied with great moderation, particularly in winter, and they muſt be ſhifted occaſionally into larger pots.

They are propagated by ſeeds and cuttings of their branches.

By ſeed.—This is procured from the Weſt Indies; ſow it in pots of light ſandy compoſt, and plunge them in a hot-bed under glaſſes, or in the bark-bed in the ſtove; they will readily grow; and when the plants are two or three inches high, prick them in ſeparate ſmall pots; which plunge alſo in the bark-bed, &c.

By cuttings.—Any time in ſummer, take off ſome cuttings of the branches, which previous to planting, as being very ſucculent, ſhould be laid in the ſtove two or three weeks, or more, as it ſhall ſeem neceſſary, till the wound made by the amputation from the parent plant is perfectly healed and dried over, to prevent their rotting; then plant them in pots of light dry earth, and plunge them in the bark-bed, giving occaſional ſhade from the mid-day ſun; and very moderate

ſhade from the mid-day ſun; and very moderate waterings; and they will be rooted in a month or ſix weeks.

POINCIANA, Barbadoes Flower-Fence, or Spaniſh Carnation.

It conſiſts of ſhrubby flowering exotics of the Indies, proper for our hot-houſe collections; of upright branchy growth, garniſhed with decompound pinnated leaves; and the branches terminated by long ſpikes of beautiful pentapetalous flowers.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, is five oblong, concave, deciduous leaves. COROLLA, is pentapetalous, four of the petals roundiſh, and nearly equal, and the fifth is larger, deformed and crenated. STAMINA, ten very long, briſtly, declinated filaments, having oblong antheræ. PISTILLUM, a long, awl-ſhaped, declinated germen, long ſtyle, and obtuſe ſtigma. PERICARPIUM, an oblong compreſſed pod, having tranverſe partitions, containing many plane nearly oval ſeeds.

The chief ſpecies are,

[1]POINCIANA *Pulcherrima.*

*Fair Poinciana, or Double Spined Barbadoes Flower-Fence.*] Hath a ſhrubby, upright, ſtraight ſtem, branching ten or twelve feet high, armed with double ſpines, at each joint; large, decompound, pinnated leaves, of numerous, oblong, obtuſe folioles; and the branches terminated by long looſe ſpikes, of large golden, yellow, beautifully variegated flowers.

[2]POINCIANA *Bijuga.*

*Bijugated Single-ſpined Poinciana.*] Riſes with a ſhrubby, upright, ſtraight ſtem, dividing into ſpreading branches, armed with ſhort ſingle ſpines; decompound pinnated leaves, of numerous, roundiſh, emarginated lobes; and the branches terminated by looſe ſpikes, of yellowiſh purple flowers.

[3]POINCIANA *Elata.*

*Spineleſs Poinciana.*] Hath a ſhrubby, ſpineleſs ſtem and branches; bipinnated leaves, of many ſmall oblong, oval, entire lobes; and looſe ſpikes of flowers, having leathery cups, and very long, dark purple filaments.

Theſe beautiful ſhrubs flower here in our ſtoves, in autumn, or beginning of winter, very ornamentally, imparting an agreeable fragrance; but are not ſucceeded by ripe ſeed in England.

As they are exotics of both Indies, they muſt be always kept in pots, and placed conſtantly in the hot houſe.

Their propagation is by ſeed, which we receive annually from the Weſt Indies. Sow it in pots of light earth, and plunge them in any hot-bed, or in the ſtove bark-bed; they will ſoon come up abundantly, which when about three or four inches high, prick them into ſeparate ſmall pots, plunging them alſo in the bark-bed, and, giving occaſional waterings, and they will make great progreſs. As they advance in growth, ſhift them with balls into larger pots; and grant them ſupplies of water, plentifully in ſummer, but always very moderate in winter. Thus they will grow freely, advance faſt in height, and in a few years begin to exhibit their elegant flowers.

POLEMONIUM, Greek Valerian, or Jacob's Ladder.

The plants are herbaceous, fibrous-rooted, flowery perennials, for the pleaſure-ground; ſending up annual ſtalks from about ten or twelve, to eighteen inches high, adorned with pinnated leaves, and terminated by bunches of monopetalous, rotated, five-parted flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is monopetalous, five-parted, and permanent. COROLLA, is monopetalous, and wheel-ſhaped, divided at top into five parts. STAMINA, five ſhort inclined filaments, having roundiſh antheræ. PISTILLUM, an oval acute germen, filiform ſtyle, and a trifid revolute ſtigma. PERICARPIUM, a three-cornered, trivalved, trilocular capſule, having many irregular ſeeds.

The moſt noted ſpecies are,

[1]POLEMONIUM *Cæruleum.*

*Blue Greek Valerian*, or *common Jacob's Ladder.*] Hath fibrous roots, crowned by a cluſter of pinnated many-lobed leaves, and upright, channelled, hollow ſtalks, about half a yard high; garniſhed with pinnated leaves, of ſeveral pair of alternate lobes, terminated by an odd one; and the ſtalks terminated by cluſters of blue flowers, having the calix larger than the corolla.

*Varieties.*] White-flowered—variegated-flowered—woolly-cupped.

[2]POLEMONIUM *Reptans.*

*Creeping Greek Valerian.*] Hath very creeping roots, upright branchy ſtalks, about a foot high, pinnated leaves, of ſeveral pair of narrow alternate lobes; and the ſtalks terminated by bunches of light blue flowers, nodding or drooping downwards.

Both the ſpecies flower in May and June;

the flowers are always collected into bunches; each flower is of one petal, divided above into five roundiſh ſegments; and are ſucceeded by plenty of ſeed in autumn.

Theſe plants are hardy: the firſt grows wild in thickets, in ſome parts of England, and other parts of Europe; and the ſecond in Virginia; and both the ſorts are cultivated in gardens for ornament, in the flower-compartments of the pleaſure-garden; are abiding by the roots, and ſend up ſtalks annually in ſpring, for flowering.

Their propagation is by ſeed, and by parting the roots; but the ſeedlings are generally the fineſt plants: parting the roots, however, is the only certain method to continue the variegated kind, and any other ſingular variety.

By Seed.—Sow it in ſpring, in any bed or border of common earth, and rake it in; the plants will ſoon come up abundantly, which, when two or three inches high, prick out a quantity in nurſery-rows, ſix inches aſunder, to remain till autumn; then may be tranſplanted, where they are finally to remain; and they will flower the following ſummer.

By parting the Roots.—Autumn, when the ſtalks decay, or early in ſpring, before new ones begin to ſhoot, is the proper time; and is performed in the common way.

POLYANTHES, Tuberoſe, or Indian tuberous Hyacinths.

It is an herbaceous, bulbo-tuberous-rooted, beautiful flowery perennial, an exotic of India, riſing with annual ſtalks, three or four feet high, terminated by a long ſpike of many large monopetalous, ſix-parted, liliaceous flowers, of great beauty, and delightful fragrance.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, is monopetalous, infundibuleforme, with an oblong incurved tube, divided above into ſix oval ſpreading ſegments. STAMINA, ſix thick obtuſe filaments, terminated by very long linear antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, crowned by a thick trifid ſtigma. PERICARPIUM, a roundiſh, obtuſely trigonal capſule, with three cells, having numerous, plane, ſemi-orbicular ſeeds, in a double range.

There is but one ſpecies, conſiſting of ſome varieties, all of which being exotics of tender quality, requiring aid of artificial heat, under ſhelter of frames and glaſſes, &c. to bring them to flower in perfection in this country.

The ſpecies is,

POLYANTHES *Tuberoſa.*

*Polyanthes or Tuberoſe.*] Hath an oblong, bulb-like, tuberous, white root; crowned with a few long very narrow leaves; amidſt them an upright, ſtraight, firm ſtem, three or four feet high, terminated by a long ſpike of large white flowers, arranged alternately.

*Varieties.*] Common tuberoſe, with ſingle flowers,—double flowered,—dwarf ſtalked,—variegated leaved.

They all flower here in June, July, and Auguſt: the flowers are funnel or bell-ſhaped; garniſh the upper part of the ſtem, in a long ſpike, conſiſting of from ten to twenty or more ſeparate flowers, in alternate arrangement; the lower flowers opening firſt, which are ſucceeded by thoſe above, in regular order, making in the whole a moſt beautiful appearance, highly enriched with a moſt fragrant odour.

The common ſingle-flowered Tuberoſe, is the ſort the moſt commonly cultivated, as it generally blows the moſt freely, and poſſeſſes the fineſt fragrance.

The double flowered kind, alſo highly merits culture, as when it blows fair, it makes a ſingularly fine appearance.

The dwarf, and the variegated kind, are inferior to the other two, but may be cultivated for variety.

All the varieties being exotics from warm countries, although they are made to flower in great perfection in our gardens, by aſſiſtance of hot-beds, they will not proſper in the open ground, and do not encreaſe freely in England; ſo that a ſupply of the roots is imported hither annually from Genoa, and other parts of Italy, by moſt of the eminent nurſery and ſeedſmen, and the Italian warehouſe-keepers; generally arriving in February or March, time enough for the enſuing ſummer's bloom; and are ſold commonly at the rate of twelve or fifteen ſhillings per hundred, being careful always to procure as large roots as poſſible, for on this depends the ſucceſs of having a complete blow.

They requiring artificial heat to blow them in this country; are planted in pots, and plunged in a hot-bed, under a deep frame, furniſhed with glaſs lights; or placed in a hot-houſe, where they may be blowed to great perfection, with little trouble.

The principal ſeaſon for planting them is March and April; obſerving, however, that in

in order to continue a long ſucceſſion of the bloom, it is proper to make two or three different plantings, at about a month interval; one in March, another in April, and a third the beginning of May; whereby the blow may be continued from June until September; obſerving, as above mentioned, they may be flowered either by aid of a common dung, or bark hot-bed, or in a hot-houſe; and the following is the methods.

Firſt by common Hot-beds.—In March or April, &c. as above obſerved, make a moderately ſubſtantial hot bed of dung or tan, in dimenſions ſuitable to any of the deepeſt hot-bed frames; and when the bed is become of a proper temperature of heat, prepare to put in the roots, previouſly planting them in pots, as directed below; obſerving, that if a dung hot-bed, lay in ſix inches depth of earth, or old tan, in which to plunge the pots, but if of bark or tan, no earth is neceſſary, as the pots may be plunged immediately into the bark.

The hot-bed being ready, and having procured the roots, and a due quantity of pots twenty fours one for each root; then having light rich earth, fill the pots therewith; and, after having diveſted the roots of all looſe outer ſkins, and all off-ſets, plant one in each pot, in depth, ſo as the top of the root be about an inch below the ſurface of the earth: this done, directly plunge all the pots in the hot-bed cloſe together, ſo as the bed may contain the number required; and as ſoon as they are all thus placed, put on the lights of the frame.

Being thus planted and placed in the hot-bed, obſerve their culture as follow: admit a portion of freſh air daily, by tilting the upper ends of the lights; but keep them cloſe down on nights: give alſo moderate waterings, which however apply very ſparingly, till the roots begin to ſhoot; then repeat the waterings freely every two or three days, or as you ſhall ſee occaſion; likewiſe obſerving, that when the ſhoot begins to advance, to admit freſh air more freely, in proportion to ſtrengthen the ſtems, according as they advance in height: and when they have riſen near the glaſſes, it is proper to deepen the frame, either by the addition of another at top, or by raiſing it at bottom ſix or eight inches, in order to give the ſtems ſufficient room to ſhoot to their full ſtature, repeating this, once or twice, as the growth of the plants renders it neceſſary, ſtill alſo indulging them with plenty of water, and a large portion of freſh air daily, either by tilting the lights as above-ſaid, or that when the plants are advanced ſome tolerable height, and the warm ſeaſon alſo a little advanced, the lights may be taken away entirely occaſionally in fine mild days, which will ſtrengthen and inure them gradually to the full air: but always draw the lights on again towards the evening, or at the approach of a ſharp air, cold blaſt, or heavy rains; obſerving, towards the middle or latter end of May, or beginning of June, according to the temperature of the ſeaſon, to begin to expoſe them fully, only giving occaſional ſhelter in cold nights, or very wet weather, either of the glaſſes, or mats ſupported on hoop arches, till they begin to flower, which will be about the middle or latter end of June, or beginning of July; when the plants in their pots may be removed where wanted; either to adorn any of the garden compartments, or any apartment of the habitation.

Place to each plant a tall ſtraight ſtake; to which faſten the ſtem for ſupport.

They muſt ſtill be duly ſupplied with water all the time of their bloom; they will require it every other day, or oftner, in very hot dry weather.

Obſerve, as aforeſaid, that, in order to continue a long ſucceſſion of bloom of this flower, two more parcels of roots ſhould be planted; one in April, about a month after the firſt, and another parcel in May; each planting to be in pots, as already directed; and plunged in a hot-bed under ſhelter of frames and glaſſes, or an awning of mats every night and cold weather: thoſe however planted late in April or in May, will need only a moderate hot bed, juſt to ſet the roots agoing at firſt, and will ſucceed tolerably, with only a protection of hoop arches acroſs the bed, for the ſupport of mats occaſionally in cold nights.

Sometimes roots planted in May in the full ground, will ſhoot tolerably ſtrong, and produce flowers in autumn.

It is however the moſt eligible way to allow them the aſſiſtance of a hot-bed as above, otherwiſe of a hot-houſe, as directed below; for one or other of theſe aids is the only method by which we can blow theſe flowers in full perfection.

*By aſſiſtance of a Hot-houſe.*] Where there is the convenience of a hot-houſe, we may blow tuberoſes in great perfection with very little trouble. Plant the roots any time in

ſpring, in pots as above adviſed; and if there is room in the bark-bed, plunge them to their rims; if not, place the pots any where towards the front of the houſe; but they will ſhoot more freely if plunged in the bark-bed; give occaſional waterings as directed in the hot-bed culture, and they will ſhoot and flower ſtrong in their due ſeaſon; and by a repetition of planting a few at three or four weeks interval, you may continue a bloom from April or May, until autumn.

*Method of Propagation.*

With reſpect to the propagation of theſe plants, it is principally by off-ſets of the roots.

The blowing roots that are brought annually from abroad, for ſale, are often furniſhed with off-ſets, which ought to be ſeparated, previous to planting; thoſe alſo that are planted here in our gardens, frequently furniſh off-ſets, fit for ſeparation in autumn when the leaves decay; they muſt then be preſerved in ſand all winter in a dry ſheltered place; and in the beginning of March, plant them either in a bed of light dry earth in the full ground, or to forward them as much as poſſible, allow them a moderate hot-bed, and in either method indulge them with ſhelter in cold weather, either of a frame and lights, or arched with hoops and occaſionally matted; but let them enjoy the full air in all mild weather, giving alſo plenty of water in dry weather, during the ſeaſon of their growth in ſpring and ſummer.

Thus let them grow till their leaves decay in autumn; then take them up, clean them from earth, and lay them in a box of dry ſand to preſerve them till ſpring, at which time, ſuch roots as are large enough to blow may be planted and managed as already directed, and the ſmaller roots plant again in a nurſery-bed, to have another year's growth; afterwards plant them for flowering.

POLYGONUM, knot-graſs.

This genus conſiſts of herbaceous perennials and annuals, for adorning the pleaſure-garden, and for medical and other uſes; riſing from about ſix inches to ten feet high, in different ſorts, garniſhed with oval and ſpear-ſhaped leaves, and terminated by branchy ſpikes of ſmall but numerous apetalous flowers.

Claſs and order, *Octandria, Trigynia.*

*Characters.*] CALIX, is divided into five oval ſegments, coloured within, and permanent. COROLLA, none, there being no petals. STAMINA, eight, very ſhort filaments, crowned with roundiſh antheræ. PISTILLUM, a triquetrous germen, three very ſhort ſtyles and ſimple ſtigmas. PERICARPIUM, none, each floret having a ſingle triquetrous ſeed wrapped in the permanent calix.

The principal ſpecies for our purpoſe are two perennials, and two annuals.

*Perennial Kinds.*

Theſe are cultivated in many gardens for variety, but their chief merit is for medical uſe.

[1]POLYGONUM, *Biſtorta.*

*Biſtort or Greater Snakeweed.*] Hath a thick oblique intorted root, blackiſh without, and red within; a ſimple round ſlender ſtem near two feet high, oval leaves, having decurrent foot-ſtalks, and the ſtalk terminated by thick ſhort ſpikes, of whitiſh-red flowers.

[2]POLYGONUM, *Vivaparum.*

*Vivaparous Polygonum*, or *ſmaller Biſtort.*] Hath a thickiſh root, a ſimple ſlender ſtem, half a foot high, ſpear-ſhaped leaves, and the ſtalk and branches terminated by long ſpikes of whitiſh-red flowers.

Both theſe perennials flower in May and June, ſucceeded by ripe ſeeds in Auguſt.

They grow wild in England, &c. the firſt in moiſt places, the other in mountainous ſituations; are in great eſtimation for medical purpoſes; the root being the part uſed.

*Annual Kinds.*

The firſt of theſe is a noble ornamental plant, commonly called *Perſicaria*; the other is an eſculent.

[3]POLYGONUM *Orientale.*

*Oriental Polygonum, commonly called Perſicaria.*] Hath fibrey roots, an upright, robuſt, ſtrong, jointed ſtem, riſing eight or ten feet high, dividing at top into ſeveral branches; very large oval-lanceolate alternate leaves, on broad foot-ſtalks half ſurrounding the ſtem; and all the branches terminated by long, ſlender, hanging ſpikes of reddiſh-purple heptandrous and digynious flowers, from July till October.

This is a noble annual for the decoration of the large compartments of the pleaſure-garden.

[4]POLYGONUM *Fagopyrum.*

*Fagopyrum, Buck-wheat*, or *Brank.*] Riſes with an upright ſmooth branchy ſtem, from about a foot and a half to a yard high, heart-ſhaped-ſagittated leaves, and the branches terminated by cluſters of whitiſh flowers, ſucceeded

ceeded by large angular ſeeds; excellent for feeding pigeons, and moſt ſorts of poultry.

All theſe plants are hardy, and ſucceed in almoſt any ſoil and ſituation; the two firſt are perennial in root, and the third and fourth are annual, wholly decay at the end of ſummer, or early in winter.

As to their merit in gardening, the following are the particulars:

The firſt two ſorts are retained in ſome curious gardens, for variety; but their chief merit is for medical purpoſes: they are powerful aſtringents, and are uſed both internally and externally; eſteemed very efficacious in hæmorrhages, and other fluxes; and good to heal ſore mouths.

Third ſort *Oriental Polygonum*, or *Perſicaria*, is a moſt elegant annual for the embelliſhment of the pleaſure-ground; it aſſuming a majeſtic tree-like growth by its erect luxuriant ſtem, and branchy head; which being garniſhed with noble large foliage, and numerous pendulous ſpikes of flowers, in conſtant ſucceſſion three or four months, exhibits a very ornamental appearance from June or July, until October, and is ſo eaſy of culture, that from its ſcattered ſeeds in autumn young plants riſe ſpontaneouſly in abundance the enſuing ſpring, and ſhoot up ſo rapidly, as to attain ſix or eight feet ſtature by July, when they generally begin flowering, and continue till attacked by the froſt, then totally periſh; ſo that a freſh ſupply muſt be raiſed from ſeed annually.

The fourt ſort (*Buck-Wheat*) is a ſort of corn, and is frequently cultivated both by way of fodder, cutting its ſtalks while young and green to feed cattle; and for its grain to feed pigeons, poultry, hogs, &c. it flouriſhes in any ſoil and ſituation, but generally thrives beſt in light dry earth; and the drieſt ſeaſons ſeldom retards its growth.

*Method of propagating all the Sorts.*

The firſt and ſecond ſort are eaſily propagated in plenty, by parting the roots in autumn.

The third ſort, *Oriental Polygonum*, being annual, is always propagated from ſeed annually; either in the full ground, or by aid of hot-beds.

By ſowing in the full ground—Some ſeed may be ſowed both in autumn, as ſoon as ripe, and in ſpring, about the borders, in patches; the autumn-ſowed plants, although they rather riſe ſparingly, yet thoſe that ſucceed, generally riſe earlier and ſtronger in the ſpring following, than the ſpring-ſowed plants; it is however proper to ſow in both ſeaſons; ſome of which may be in a warm border for tranſplanting; and others about the borders in patches, finally to remain, covering the ſeed half an inch deep; they will come up about April or May, if a fine ſeaſon; which, when three or four inches high, thoſe deſigned for tranſplantation ſhould be planted out ſingly, about the different compartments; and of thoſe ſowed in patches, thin out the weakeſt in moiſt weather, leaving only one of the ſtrongeſt plants in each patch; and thoſe thinned out, may alſo be planted ſingly where they may be required. According as the plants in general advance ſome conſiderable height, place a ſtout ſtake to each for ſupport, which is all the culture they require; and they will flower in due ſeaſon, and furniſh plenty of ſeed.

From the ſcattered or ſelf-ſown ſeed in autumn, many young plants often riſe in ſpring, and flouriſh without any trouble.

By hot-beds.—As ſometimes in bad ſeaſons, or in cold wet ſoils, the ſowings in the full ground either riſe but ſparingly, or not till late in ſpring, probably May or June; it is therefore proper alſo to ſow ſome in a hot-bed in March, with other annuals, ſuch as African and French marigolds, China aſters, &c. for tranſplantation, which will forward them conſiderably; but they muſt be planted out in May or June before they draw up; or if previouſly pricked upon another hot-bed, ſix or eight inches aſunder, and arched over with hoops, and ſheltered with mats in cold nights; and here to have three or four weeks growth, it would bring them more conſiderably forward, and they may readily be moved with large balls of earth about their roots, for their final tranſplantation.

The fourth ſpecies, *Buck-Wheat*, is alſo propagated by ſeed annually, in any open ground, which ſow in April or May, either broad-caſt and raked, or harrowed in, or in ſhallow drills, ten or twelve inches aſunder, the plants will ſoon come up, and be fit to mow for cattle in eight or ten weeks, or if to ſtand, will produce a crop of grain in three or four months.

POPULUS, Poplar-tree; comprehending the Abele, and Aſpen-tree, &c.

This genus is compoſed of hardy deciduous trees, valuable for ornamental and foreſt-tree plantations; they riſing to a conſiderable height

height and magnitude, garniſhed with large roundiſh angulated and heart-ſhaped ſimple leaves, and dioecious apetalous flowers, collected into long amentums.

Claſs and order, *Dioecia*, *Octandria*.

*Characters.*] CALIX, male and female flowers on ſeparate trees, collected into oblong, looſe, imbricated amentums, compoſed of oblong ſcales, each ſcale forming a cup to a ſingle floret. COROLLA, no petals, but a monophyllous nectarium. STAMINA, eight filaments, having large four-cornered antheræ. PISTILLUM, an oval acuminated germen, very ſhort ſtyle and quadrifid ſtigma.—PERICARPIUM, an oval bilocular capſule, and numerous oval pappous ſeeds.

There are five ſpecies, all of the tree kind, deciduous, and of hardy temperature; will thrive in almoſt any ſoil and ſituation, but are the moſt proſperous in moiſt grounds, particularly the firſt three ſorts, which thrive exceedingly in marſhy or boggy land, or any watery ſituation.

The ſpecies are.

[1]POPULUS *Alba.*

*White Poplar, commonly called Abele-tree.*] Riſes with an upright ſtraight trunk, and regular branchy head, to a great height, having a whitiſh ſmooth bark, roundiſh leaves, indented into ſeveral angles, of a dark-green above, and are downy and white underneath.

*Compriſes theſe Varieties.*] Large-leaved White Poplar — ſmall-leaved — variegated-leaved.

[2]POPULUS *Nigra.*

*Black Poplar.*] Riſes with a ſtraight trunk, and full branchy head, to a conſiderable height; having deltoide, heart-ſhaped, acuminate, ſerrated, light green leaves.

[3]POPULUS *Tremula.*

*Trembling Poplar, or Aſpen-tree.*] Riſes with an upright large trunk, and a full branchy head, many feet high, having a grey bark, roundiſh leaves indented into angles, ſmooth on both ſides, with a conſtant tremulous motion.

The leaves of this ſpecies having long ſlender foot-ſtalks, are rendered ſo very tremulous, that they have a conſtant wavering or trembling motion; hence the name *Populus Tremula.*

[4]POPULUS *Balſamifera.*

*Balſamiferous Carolina Poplar.*] Riſes with an upright large trunk, and a large regular branchy head, to a great height, having a whitiſh ſmooth bark, and the young ſhoots cornered; large, almoſt heart-ſhaped, indented, light ſhining-green leaves.

This is a very elegant ſpecies of *Populus*, of very free growth, and the leaves remarkably large and ornamental.

[5]POPULUS *Heterophylla.*

*Heterophyllous Virginia Poplar.*] Riſes to a great height, having large heart-ſhaped leaves, hairy at their firſt appearance.

The two following ſorts are alſo ſuppoſed of this genus.

*Tacamahacca Poplar, commonly called Tacamahacca or Balſam-tree.*] Is of moderate growth, branching out into a full regular head, having middling-ſized leaves, ſome oval, others heart and ſpear-ſhaped, whitiſh underneath, and of a very balſamic odoriferous nature; good to cure green wounds.

*Lombardy Poplar.*] Riſes with a very ſtraight ſtem, branching erectly, forming a fine regular head, and grows to ſome conſiderable height; having large, roundiſh, acuminate, ſmooth, light-green leaves—is a remarkable faſt ſhooter, and highly merits culture.

In all theſe trees the leaves are univerſally of the ſimple kind, moderately large, and form a diſtinguiſhable diverſity in plantations in ſummer; they expand in ſpring and decay in autumn, like the reſt of the deciduous tribes.

All the ſorts flower annually in the ſpring, but the flowers being only ſmall katkins, make no ornamental ſhow; they are all of the claſs *Dioecia*, *i. e.* male and female on ſeparate trees, collected into oblong imbricated amentums or katkins, two or three inches long, the flowers being ſmall florets without petals, ſituated under the ſcales of the amentum, appear commonly in March or April; the males come out firſt, and the females in a week after, and in about five or ſix weeks are ſucceeded by ripe ſeed, which is frequently diſſeminated by the winds all around to a conſiderable diſtance, and often productive of many young plants.

Theſe trees are all of remarkably quick growth, often making ſhoots whilſt young, from three or four to eight or ten feet long in one ſummer, eſpecially in moiſt ſoils, in which they principally delight, and make the greateſt progreſs.

As to their uſes in gardening, the following are the particulars.

They may be employed occaſionally for ornament in out-grounds, not near fine lawns

and

and walks, on account of the great litter the falling of their katkins occaſion; but are excellent for planting towards the boundaries of parks, paddocks, and fields, the ſides of rivers and brooks, and to interſperſe with other trees in large plantations. The White Poplar, or Abele, in particular, alſo the Carolina, Tacamahacca, and Lombardy Poplar, are very ornamental trees, and are finely adapted to be employed in aſſemblage in forming large avenues, open groves, and clumps in parks, &c. all the ſorts may be employed to advantage in any large tracks of plantation.

If required to ornament any marſhy or boggy grounds with plantation, no trees are better adapted for that uſe than Poplars, eſpecially the firſt three ſpecies, all of which thrive remarkably in moiſt or boggy ground, and will readily grow by cuttings, either of young ſhoots or in truncheons.—See their *Propagation.*

As foreſt or timber-trees, the following three ſorts, White, Black, and Tremulous Poplar are proper to be employed for that purpoſe, eſpecially in any moiſt boggy ground, where few other trees will thrive: they however will ſucceed in any other common ſoil poor or rich, but in a boggy or very moiſt ground they will be ſo expeditious in growth as in ſix or ſeven years they will afford a conſiderable advantage, eſpecially if planted cloſe to allow of thinning, for a fall of poles, ſpars, and for fire-wood, &c. beſides leaving a ſufficient number of ſtandards at proper diſtances to grow up to timber, and the ſtools of the firſt fall remaining, ſhoot up again and afford a fall every four or five years, ſtill leaving the timber ſtandards.

Any boggy or marſhy land may be improved to much advantage by coppices of theſe trees, to cut every four, five, or ſix years for poles, and other ſmall purpoſes; being planted in rows a yard aſunder, and in ſeven years they will be fit to cut for many ſmall uſes, and the ſtools ſhooting up again ſtrong, will afford a cutting every four or five years after. See PLANTATIONS.

For all the above purpoſes young trees are propagated and raiſed, as directed below in their propagation.

*Method of Propagation.*

All the ſorts of *Populus* are eaſily propagated by cuttings, layers, and ſuckers.

By Cuttings.—October and November is a good ſeaſon for this work, or even any time in winter until March, in open weather. This is the moſt expeditious mode of propagating all theſe trees, for cuttings thereof grow freely without any trouble; either cuttings of the young year-old ſhoots, a foot and half long, planted a foot deep, or large truncheons of two, three, or more years growth, from about a yard to five or ſix feet long, planted in moiſt places: though theſe large cuttings or truncheons are not proper for any general plantation, only juſt in ſome particular parts, in a boggy or watery ſituation, where ſhade and ſhelter may be required as ſoon as poſſible, in which may be planted a quantity finally to remain, planting them two or three feet deep.

But, in order to raiſe plants for any regular plantation, or for a quantity of handſome ſtandards, it is the moſt eligible to raiſe them principally from young cuttings of one year's growth, or two at moſt; procure therefore a quantity of theſe young cuttings, about fifteen or eighteen inches long, and plant them in nurſery-rows a yard aſunder, placing each cutting two parts of three in the ground, and about a foot diſtance in the lines, they will readily take root, and make good ſhoots the following ſummer, being careful to trim off ſtraggling laterals, in order to encourage the leading ſhoot to grow ſtraight, and aſpire more expeditiouſly in height; and after having from two to four or five years growth here, they may be tranſplanted finally for the purpoſes above mentioned.

By Layers.—In autumn chuſe any lower young ſhoots conveniently ſituated, lay them by ſlit-laying, they will be well rooted and fit to tranſplant by autumn following, in nurſery-rows to have two or three years growth.

By Suckers.—Some of the ſorts ſend up abundance of ſuckers from the roots, which may be taken up after the fall of the leaf, and planted in nurſery-rows, as directed for the cuttings; they will form good plants in two years.

The plants raiſed by all the above methods, will, after having obtained from two or three to five or ſix years growth, be of proper ſize for furniſhing any of the aforementioned plantations.

PORTULACA, Purſlane.

Two ſpecies are found in our gardens; one a low herbaceous ſucculent annual, a ſallad herb; the other a low ſhrubby perennial for the

the green-houſe, or ſtove collection, both riſing only ſix or eight inches high, garniſhed with ſmall ſucculent leaves, and ſmall pentapetalous flowers.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX is ſmall, bifid, and placed on the germen, and permanent.—COROLLA, five plane, obtuſe, erect petals.—STAMINA, from twelve to nineteen ſhort capillary filaments, having ſimple antheræ.—PISTILLUM, a roundiſh germen, ſhort ſimple ſtyle, and five oblong ſtigmas.—PERICARPIUM, an oval covered capſule, of one cell, having many ſmall ſeeds.

There are ſeveral ſpecies, but the two following are the moſt noted.

1 PORTULACA *Oleracea* (*Annual.*)

*Common culinary Purſlane.*] Riſes with herbaceous, low, ſucculent, branchy ſtalks, ſix or eight inches high, garniſhed with wedge-ſhaped, thick, ſucculent leaves, and ſmall cloſe-ſetting flowers.

*Compriſes two Varieties.*] Green Purſlane, having deep-green leaves.—Golden Purſlane, having yellow leaves; both the varieties riſing from the ſame ſeed.

Theſe herbs are excellent to mix in ſummer ſallads.

PORTULACA, *Anacampſeros* (*Perennial.*)

*Anacampſeros, or Shrubby Cape Purſlane*] Riſes with a ſhrubby branchy ſtalk, about ſix inches high, oval, gibbous, ſucculent leaves, and the ſtalks terminated by ſmall cluſters of red flowers.

Both theſe plants are of a ſucculent nature; the firſt is an herbaceous annual, for culinary uſes; and the ſecond a ſhrubby perennial, cultivated by the curious for variety; are both exotics of a tender quality, of the temperature of green-houſe and ſtove plants.

*The common Culinary Purſlane* is raiſed annually from ſeed for ſummer uſe, both as a ſallad and pot-herb, is of a moiſt cold nature, and an excellent ingredient to mix in ſummer ſallads, but not proper for winter uſe; the plant being tender muſt be raiſed either in a hot-bed, or in a warm border, in which it will not ſucceed before April or May.

The ſhrubby ſort muſt be kept in pots of dry ſoil, and placed in the hot-houſe collection.

*Method of Propagation.*

The propagation of the *Common Purſlane* is by ſeed annually in ſpring and ſummer, for, in order to continue a ſucceſſion of young plants for uſe, it is proper to ſow ſeveral different times from March or April until June, July, or Auguſt, at about three weeks interval, obſerving, if required, to have it early: the firſt ſowing may be performed in a ſlender hot-bed in February or March, and the other ſowings may be in a warm border of lightiſh earth in April and May; though, as the warm ſeaſon advances, the ſowings may be in any open bed or border of light ground. The ſeed may either be ſowed in ſhallow drills, and covered about a quarter of an inch deep, or all over the ſurface, covering it that depth, or may be lightly raked in: give occaſional waterings in dry weather, both before and after the plants come up, which are to remain where ſowed, and they will be fit to cut for uſe in three or four weeks. In gathering them for uſe, cut off their young tops with a knife, they will ſhoot out again after each cutting.

To ſave ſeed of this ſort leave ſome ſtrong plants of the April ſowing, they will flower and ripen ſeeds freely towards autumn.

The ſecond ſort is propagated by cuttings, any time from April till June or July; plant them in pots of light dry earth, and if plunged in the bark-bed they will root the ſooner, giving occaſional ſhade till rooted, and moderate watering.

POTENTILLA, *Cinquefoil.*

The genus conſiſts of one noted ſhrubby ſpecies, and near thirty herbaceous kinds; the former is a hardy deciduous flowering ſhrub for the pleaſure-ground; and the others having but little merit as garden plants, only a few of them are ſometimes admitted in the herbaceous collection for variety. All the ſorts are of moderate growth, ſome growing erect, others trailing, and garniſhed with pinnated and other compound leaves, and pentapetalous flowers.

Claſs and Order, *Icoſandria Polygynia.*

*Characters.*] CALIX is menophyllous, half cut into ten parts, alternately ſmaller, and reflexed.—COROLLA, five, roundiſh, ſpreading petals, inſerted into the calix.—STAMINA, twenty awl-ſhaped ſhort filaments, having elongated-lanulated antheræ.—PISTILLUM, numerous ſmall germina collected into a head, many ſlender ſtyles, having obtuſe ſtigmas.—PERICARPIUM, none, a head of ſeeds placed on the common receptacle, which lodges in the calix.

There are about ſix or ſeven ſpecies found in our gardens, one of which is ſhrubby, the others herbaceous.

*Shrubby*

*Shrubby kind.*

[1]POTENTILLA *Fruticosa.*

*Shrubby Potentilla, commonly called Shrub Cinquefoil.*] Riſes with a ſhort ſhrubby ſtem, dividing into a branchy, full head, three or four feet high; cloſely garniſhed with pinnated leaves, of five, oblong, narrow, acute-pointed folioles, pale green above, and whitiſh underneath; and the branches terminated by cluſters of large, ſpreading, yellow flowers.

This is a beautiful deciduous flowering ſhrub, worthy a place in every curious collection.—It grows wild in Yorkſhire and other northern parts of England, &c. but has been long a reſident of gardens as an ornamental ſhrub.

*Herbaceous perennial kinds.*

There are about five or ſix of theſe kinds common to our gardens; the firſt of which grows wild in England, and is rarely cultivated; the others are of foreign growth in different parts of Europe.

[2]POTENTILLA *Reptans.*

*Creeping common five-leaved Potentilla, or five-leaved graſs.*] Hath a thick fibrey root, ſlender, trailing, repent ſtalks, digitated, five-lobed, petiolated leaves, and yellow flowers, ſingly.

[3]POTENTILLA *Rupeſtris.*

*Mountain upright Cinquefoil.*] Hath upright ſtalks, eight or nine inches high; pinnated, five and three-lobed, alternate leaves, having oval crenated lobes, and the ſtalks terminated by ſmall white flowers.

[4]POTENTILLA *Recta.*

*Erect, ſeven-lobed, Yellow Cinquefoil.*] Hath erect ſtalks, ſeven-lobed leaves; having the lobes ſpear-ſhaped and ſerrated; green and hairy on both ſides, and the ſtalks terminated by corymboſe cluſters of yellow flowers.

[5]POTENTILLA *Fragaroides.*

*Straberry-like trailing Potentilla.*] Hath a ſomewhat tuberous root, furniſhed with many long fibres, long trailing ſhoots, rooting at the joints; pinnated, moſtly three-lobed leaves, having oval lobes, with the extreme lobe the largeſt, and cluſters of ſmall white flowers.

This ſpecies bears a great reſemblance to the ſmall ſterile ſtrawberry plants.

[6]POTENTILLA *Argentea.*

*Silvery upright Potentilla.*] Hath upright ſtalks, branching a foot high; and five-lobed leaves, having the lobes wedge-ſhaped, cut on the edges, hoary and white underneath, and the branches terminated by ſmall yellow flowers.

All theſe *Potentillas* flower in June and July; the flowers are compoſed each of five roundiſh petals, and about twenty ſtamina.

They are all very hardy plants, and may be employed in the different compartments of the pleaſure-ground. The firſt ſpecies in particular, *Shrubby Potentilla*, merits a place in every ſhrubbery towards the front of the clumps, &c. and the herbaceous kinds may be diſperſed about the common compartments to increaſe the variety.

Their propagation is very eaſy.

The *Shrubby Potentilla* may be propagated abundantly by ſuckers, layers, and cuttings; all of which will readily grow, and make plants in one year, which after having two or three years growth in the nurſery, will be fit for any of the ſhrubbery compartments.

All the herbaceous kinds may be propagated by parting the roots in autumn or ſpring, or by ſeed in any of thoſe ſeaſons.

POTERIUM, Garden Burnet.

It conſiſts of two herbaceous and one ſhrubby perennial. Of the former, one is a kitchen-garden herb, the other for the pleaſure-garden, and the ſhrubby kind for the green-houſe collection; they all riſing with upright ſtalks from about a foot and a half to a yard high, in different ſorts; having pinnated leaves, and the branches terminated by ſpikes of quadripartite monoecious flowers.

Claſs and order, *Monoecia Polyandria.*

*Characters.*] CALIX, male and female flowers in the ſame ſpike, each floret having cups formed of three oval leaves. COROLLA, in the males is quadripartite, the ſegments oval, concave, and permanent, and in the females is monopetalous, and wheel-ſhaped with a ſhort tube, divided above into four oval, plane, perſiſtent ſegments. STAMINA, numerous capillary filaments, and didymous antheræ. PISTILLUM, two oval-oblong germens, two hair-like, coloured ſtyles, and pencil-ſhaped, coloured ſtigmas. PERICARPIUM, a berry incloſed in the indurated corolla, having two ſeeds.

*Herbaceous kinds.*

The firſt of theſe herbaceous kinds is an an eſculent herb, the other for variety in the pleaſure garden.

[1]POTERIUM *Sanguiſorba, (Perennial.)*

*Sanguiſorba, or common garden Burnet.*] Hath fibrey perennial roots, crowned by a large tuft of pinnated leaves, of ſix or ſeven pair of ſawed lobes, terminated by an odd

one; upright angular ſtalks, dividing, and branching a foot and a half high, terminated by oblong ſpikes of purpliſh red flowers.

This ſpecies grows wild in England, in chalky ſoils, but has been long cultivated as a choice ſallad-herb for winter and ſpring uſe, it being of a warm nature; the young leaves are the uſeful parts.

It is perennial in root, and retains its radical leaves all the year, but the ſtalks are annual.

[2]POTERIUM *Hybridum.*

*Hybrid Agrimony-leaved Montpelier Burnet.*] Riſes with upright taper, cloſely gathered ſtalks two feet high; pinnated odoriferous leaves of three or four pair of ſawed lobes, terminated by an odd one; and the ſtalks terminated by long foot-ſtalks dividing into ſmaller, each ſupporting a ſmall roundiſh ſpike of flowers.

This ſpecies often proves biennial, but by cutting down ſome of the ſtalks before they flower, it will cauſe it to multiply at bottom, and become abiding.

*Shrubby kind for the Green-houſe.*

[3]POTERIUM *Spinoſum.*

*Shrubby Spinous Burnet of Crete.*] Hath a ſhrubby ſtem and branches, riſing a yard high, armed with ſpines; ſmall pinnated evergreen leaves, of ſix or ſeven pair of lobes, terminated by an odd one, and the branches terminated by ſmall heads of greeniſh flowers.

All theſe three ſpecies flower in June and July, ſucceeded by ripe ſeeds in autumn.

They are all naturally perennial, but the two herbaceous kinds being abiding in root only; the other in root, ſtem, and branches; and the two former are hardy, and the third requires ſhelter in winter.

The firſt ſort merits culture in every kitchen-garden for winter and ſpring ſallads.

Some plants, both of the firſt and ſecond ſorts, may be introduced in the herbaceous collection in the pleaſure-garden for variety.

Keep the third ſort always in pots to have ſhelter in winter.

They are all eaſily propagated as follows.

The firſt ſort by ſeed, and by parting the roots.—Sow the ſeed in autumn or ſpring, in a border of light earth, and rake it in, and when the plants are two or three inches high, plant them out in any bed or border a foot aſunder, finally to remain.—Parting or ſlipping the roots is performed alſo in the autumn or ſpring ſeaſon, planting the ſlips as directed for the ſeedlings.

The ſecond ſort may alſo be encreaſed by ſeed and ſlips off the root, as for the former ſort.

And the propagation of the third is by ſlips or cuttings of the branches in ſpring and ſummer, planted in pots, and placed under glaſſes, giving ſhade and water; or might be forwarded more by plunging them in a hot-bed.

POTS. Garden Pots for plants and flowers.

In gardening, Pots are particularly neceſſary in the culture of all tender exotics of the of the green houſe and ſtoves, all of which muſt be planted in Pots for the convenience of moving them in and out of theſe departments as occaſion requires.

Pots are alſo exceedingly uſeful in raiſing many young ſeedlings and cuttings, that may require moving to occaſional ſhade, ſhelter, and artificial heat, likewiſe for many young plants that are tender whilſt young, requiring to be removed under ſhelter for the firſt two or three winters, but become hardy enough afterwards to bear the full air the year round; and Pots are likewiſe very convenient in in which to plant many of the more curious hardy flowering plants and others, and choice flowering ſhrubs, &c. to remove occaſionally to adorn any particular compartments.

There are about eight different ſizes of Garden Pots, which are neceſſary in order to ſuit the different ſorts of plants, as well as all ſorts of plants in their different ſtages of growth; as when the plants are young and of ſmall ſize, they may be firſt planted in ſmall Pots, and as they by degrees increaſe in bulk, ſhift them into pots a ſize larger, repeating it as often as neceſſary. See PLANTING *in* POTS and *Shifting Plants.*

The ſeveral ſizes of Pots are in regular gradation, and at the Pot-houſes each ſize has its name for the convenience of readily ſupplying the ſizes wanted for particular uſes; they being always reckoned by the caſt, from two to ſixty Pots to each, according to their ſizes, the largeſt Pots being only two to a caſt, and the ſmalleſt ſixty; ſo that as there being eight different ſizes or caſts: they are diſtinguiſhed by the following terms, twos, eights, twelves, ſixteens, twenty-fours, thirty-twos, forty-eights, and ſixties; ſo according to the above numbers there are ſo many Pots to each caſt; the ſeveral caſts from the twos,

being

being in a gradual diminution, and the price of the different caſts are the ſame; thoſe of two, &c. being as much as thoſe of ſixty, and ſo of the reſt; from two to three ſhillings is the general price per caſt at the potter's in the neighbourhood of London.

The principal places in the vicinity of London for the red pot houſes, or potters that make Garden Pots, are moſtly in the villages contiguous to the river Thames, for the convenience of water-carriage, ſuch as Lambeth, Rotherhith, Deptford, Greenwich, Hammerſmith, Brentford, Bow, &c.

In chuſing the Pots, ſee that they are burned ſufficiently hard, and ſo perfectly ſound as to ring when ſtruck with your knuckle, and that they have all holes at the bottom to diſcharge the ſuperfluous moiſture from the earth about the roots of the plants; the larger pots having generally four holes, one in the middle of the bottom, and three around the circumference thereof, at equal diſtances; but the ſmaller Pots have commonly only one hole in the middle of the bottom.

With reſpect to the proper ſizes of Pots requiſite for the different ſorts of plants, it is commonly mentioned in their reſpective genera, when any particular ſizes are neceſſary.

When we occaſionally ſpeak of ſmall Pots, it is generally to be underſtood either as ſixties, forty-eights, or thirty-twos, according to the ſorts or ſizes of the plants.

For the method of planting in Pots, &c. ſhifting plants from one Pot to another, &c. See *Planting in Pots*, under the article PLANTING.

And when any plants are become two large for Pots, they are to be ſhifted into tubs, as is often neceſſary for orange and lemon trees, great American aloes and ſome other large-growing exotics. See TUBS.

PRIMULA. Primroſe. Including Polyanthus and Auricula.

This famous genus *Primula* furniſhes a grand collection of low, herbaceous, fibrous-rooted, flowery perennials; two celebrated ſpecies in particular, *common Primroſe* and *Auricula*, have ſingular merit, as very beautiful ſpring flowers, and for each ſpecies furniſhing thouſands of varieties, are all of humble growth, with the roots crowned by a cluſter of oblong broad leaves, and low ſlender flower-ſtalks, from about three or four to to ſix or eight inches high, terminated by monopetalous, five-parted flowers, ſome ſingly, others in cluſters.

Claſs and order, *Pentandria Monogynia*.

*Characters.*] CALIX, a many-leaved involucrum, containing many ſmall flowers, each having a monophyllous, tubulous, pentagonous cup, divided into five acute erect ſegments, and is permanent. COROLLA, is monopetalous, with a long cylindric tube the length of the calix, having the limb or upper part ſpreading, and divided into five roundiſh heart-ſhaped ſegments. STAMINA, five very ſhort filaments, ſituated in the neck of the corolla, having acute erect antheræ. PISTILLUM, a round germen, ſlender ſtyle, and globular ſtigma. PERICARPIUM, an oblong, cylindric, unilocular capſule, ten-parted at top, containing numerous ſmall ſeeds.

There are ſix or ſeven ſpecies of this genus, two of which demand univerſal eſteem as flowery plants; namely, *Common Spring Primroſe*, and *Auricula*; the former of which includes all the family of the Primroſes, Cowſlips, and all the numerous varieties of Polyanthuſes; and the latter, all the vaſt train of the Auricula tribe. The *Auricula*, however, was formerly ranged as a diſtinct genus; but its general characters determining it a ſpecies of *Primula*, modern botaniſts arrange it accordingly.

'PRIMULA *Veris*.

*Spring Primroſe.*—Conſiſting of the three following principal varieties, — Common Primroſe,—Cowſlip Primroſe,—Polyanthus Primroſe; each having many varieties.

*Common Primroſe kinds.*

*Common Spring Primroſe.*] Hath thick very fibrey roots, crowned by a cluſter of large, oblong, indented, rough leaves, and numerous flower-ſtalks, from about three or four to five or ſix inches high, each terminated commonly by only one flower, of different colours and properties in the varieties.

*Varieties of theſe are.*] Common yellow-flowered Primroſe of the woods—White Primroſe — Paper-white Primroſe — Red Primroſe--Double yellow Primroſe—Double white Primroſe — double red Primroſe. — All of which varieties having generally but one flower on each ſtem, but riſe in ſuch plenty from every part as to appear almoſt covered with flowers.

They all flower abundantly in March and beginning of April, continuing a month or ſix weeks.

All theſe varieties of *Common Spring Primroſe*, are hardy perennials: the ſingle yellow ſort grows wild in woods, &c. in moſt parts of England; all the others being ſeminal or ſeedling varieties of it, that have been principally obtained by culture in gardens. The double kinds in particular have ſingular beauty; the flowers being large, and perfectly full and double, and make a fine ſhew, highly meriting culture in the beſt collections of ſpring-flowers.

Theſe varieties in general delight moſtly in ſhady ſituations, whereby all the ſorts, both ſingle and double, are proper ornaments for the borders of ſhrubberies, wilderneſs quarters, and ſhady walks, where they will flower abundantly, and make a fine appearance. Some plants may alſo be diſperſed in other more open compartments for variety.

Prodigious quantities of the ſingle Primroſe plants are brought to London, every ſpring, by the herb-women, which they gather in the neighbouring woods, when in full bloom, taking them with roots, and ſell them about the ſtreets.

The propagation of all theſe varieties is effected abundantly by ſlipping or parting the roots. Numerous ſingle kinds may alſo be raiſed from ſeed, ſowed in a ſhady border in autumn or ſpring, as directed for the Polyanthus; but raiſing ſeedlings is hardly worth practiſing, ſince they encreaſe ſo plentifully by the roots.

Remarking, however, that the propagation by ſlipping or divided the roots is the only method for encreaſing the double kinds; and as theſe ſorts are the moſt beautiful, and multiply in tolerable plenty by off-ſets, it is proper to raiſe a good ſtock of them, which may be effected with great facility every year ſoon after their flowering is paſt, as they will then be increaſed into bunches; therefore being furniſhed with ſome good roots, proceed to their propagation in autumn, about July, Auguſt, or September; taking them up out of the ground, and divide each bunch of plants into ſeveral ſlips, and directly plant them in a ſhady border of good rich earth, ſix or eight inches aſunder, and each ſlip will become a good plant, and will flower ſtrong the following ſpring.

Obſerve, it is proper to remove and part the roots of the double kinds, in particular, every year; but not to omit once in two years at moſt, in order to preſerve the plants in vigour.

### *Cowſlip kinds.*

*Cowſlip-Primroſe, or Cowſlip.*] Hath very thick fibrey roots, crowned by a cluſter of oblong, indented, round leaves, and upright firm flower-ſtalks, five or ſix inches high, terminated each by a cluſter of ſmall yellow flowers, and other different colours and properties in the varieties.

*Varieties of theſe are.*] Common ſingle yellow Cowſlip of the meadows and paſtures —Double yellow Cowſlip—Scarlet Cowſlip —Hoſe-and-hoſe Cowſlip, one flower growing out of the boſom of another, the lowermoſt ſerving as the calix; all of which varieties having the flower-ſtalks crowned by many flowers, in bunches.

They flower in April and May, continuing in ſucceſſion a month or ſix weeks.

All the varieties are hardy perennials, ſome of them inhabitants of meadows and paſture grounds, particularly the common ſingle yellow ſort, in great abundance; which ſort is of excellent uſe in medicine, and a fine cordial wine is made of the flowers. Some plants of all the varieties merit admittance in the pleaſure garden, to increaſe the variety of the ſpring bloom, but principally the double kinds, placing them in the fronts of ſome ſhady moiſt borders, &c. they do not, however, ſucceed ſo well immediately under ſhade of trees, &c. as the common Primroſes.

The propagation of theſe ſorts is principally by parting the roots, as directed above for the common Primroſe: this method of progation is, however, particularly neceſſary for all the double kinds, and having a few roots of each ſort, they will multiply exceedingly by off-ſets, and ſoon encreaſe your ſtock.

### *Polyanthus kinds.*

*Polyanthos Primroſe, commonly called Polyanthus.*] Hath thick fibrated roots, increaſing into large bunches, crowned with a cluſter of large oblong indented rough leaves; amidſt them upright flower-ſtalks ſix or eight inches high, terminated moſtly by a cluſter of ſeveral ſpreading flowers, of many different colours and variegations in the varieties.

*Varieties.*] The varieties of *Polyanthus* are innumerable in the different colours and variegations of the flowers; but the principal colours are—Purple-flowered—Red-flowered Gold-coloured—Orange-coloured, &c. each having numerous intermediate ſhades and variegations, that ſometimes in one bed or

border of ſeedlings we may diſcover many hundred different ſorts, and the varieties may ſtill be increaſed without end from ſeed; and the ſelect varieties of each ſowing may all be continued and increaſed plentifully by ſlipping the roots, which annually multiply into large bunches, and may be parted or ſlipped with the utmoſt facility into many ſeparate plants.

They all flower beautifully in April and May, and often flower again in autumn, and ſometimes in winter, in very mild ſeaſons; but the ſpring is their principal ſeaſon of flowering in the greateſt perfection, and ripen ſeeds abundantly in June or July.

This variety, *Polyanthus Primroſe*, is one of the moſt beautiful of our fibrous-rooted ſpring flowers for the open borders, remarkable for its wonderful ſeminal diverſity, all of which are hardy perennials, that flouriſh in almoſt any common ſoil and ſituation, but delight moſt in a loamy or other rich moiſt ſoil, and in a ſomewhat ſhady border; in a ſhady ſituation, however, they continue conſiderably longer in full bloom than in a ſunny expoſure; for a fierce ſun often greatly affects theſe flowers both in beauty and duration; it is therefore proper to plant a collection of the fineſt ſorts in the ſhade, not immediately under trees, &c. but in ſome eaſtward ſhady border, ſheltered by a wall, hedge, or other fence from the noon-day ſun, planting them at ſix or eight inches diſtance; and here the plants will continue flowering in full beauty a month or ſix weeks, but a quantity of different varieties ſhould alſo be diſperſed in the fronts of the ſeveral borders contiguous to the principal walks, in aſſemblage with other flowers, in which they will effect a very agreeable variety.

The Polyanthus is one of the noted prize-flowers among floriſts; many of whom are remarkably induſtrious in raiſing a conſiderable variety of different ſorts, as well as uſe every art to blow them with every requiſite perfection; for among thoſe vertuoſi, a Polyanthus muſt poſſeſs ſeveral particular properties to have admittance in their choice collections.

But there are numerous varieties of Polyanthus, that, although deſtitute of ſome of the properties required by floriſts, are nevertheleſs very pretty flowers for ornamenting the common borders.

The chief properties however of a floriſt's Polyanthus are principally the following:—

1. The ſtem or flower-ſtalk ſhall be upright, moderately tall, with ſtrength in proportion, and crowned by a good regular bunch of flowers, on ſhort pedicles, ſtrong enough to ſupport them nearly in an upright poſition 2. The florets of each bunch ſhould be equally large, ſpread open flat, with the colours exquiſite, and the ſtripes and variegations lively and regular. 3. The eye in the centre of each floret ſhould be large, regular, and bright; and the antheræ, by the floriſts called the thrum, ſhould riſe high enough to cover the mouth of the tube or hollow part in the middle of the florets, and render them what they call thrum-eyed; but when the ſtyle elevates the ſtigma above the antheræ, the eye of the tube generally appears hollow, ſhewing the ſtigma in the middle, like the head of a pin, is hence called pin-eyed, and is rejected as an incomplete flower, although its other properties be ever ſo perfect.

But although the floriſts reject a pin-eyed Polyanthus, it is the flower in its moſt perfect ſtate; and great numbers of them are of as beautiful forms, colours, and ſtripes as the thrum-eyed varieties, and demand equal attention as furniture for decorating the common flower compartments, &c. or to exhibit a general ſhew in a bed or border.

The method of propagation for the Polyanthus is, by ſeed, and by parting the roots.

By Seed.—This is the only method of propagation to gain new varieties, and to raiſe a large ſtock of plants, as a blow of many new flowers may be annually obtained for the choice collection, and a large ſupply for the common borders: the ſeaſon for ſowing the ſeed is, either in autumn, ſoon after it is ripe, or early in ſpring; in either ſeaſon of ſowing they will ſoon come up, but will not flower till the ſecond ſpring; obſerving, however, that by ſowing early in autumn, the plants generally come up freely the ſame year, be fit to plant out betimes the next ſpring, and become ſtronger plants by the ſpring following, capable of flowering in greater perfection than the ſpring-ſowed ſeedlings: remarking if you ſow in autumn let it be in July or beginning of Auguſt, and if in the ſpring, perform it in February, March, or beginning of April: and the ſowing in both ſeaſons may be performed either in large pots or boxes of rich earth, in order to move to different ſituations occaſionally, or in an eaſt border of light rich ſoil; but ſowing in pots or boxes may

may be the moſt eligible for the autumn ſowing, for the convenience of moving to a little ſhelter in froſty weather; in either method ſow the ſeed on the ſurface moderately thick, covering it evenly with light earth only about a ſtraw's breadth thick, or if ſowed in a border, it may either be raked in very light and evenly, or covered as above; the plants will appear in three or four weeks, obſerving that if ſowed in boxes, &c. they ſhould be removed to a ſhady border during the warm weather, and thoſe of the autumn ſowing to a warm ſituation in winter, allowing them alſo ſome protection from froſt.

In the ſpring, or beginning of ſummer, when the plants of either ſowing are one or two inches high, they ſhould be planted out in ſomewhat ſhady borders, as formerly mentioned, about five or ſix inches aſunder, to remain for flowering; which they will all effect the following ſpring, when thoſe of good properties ſhould be marked, and the others may be tranſplanted into the common flower-borders.

Obſerve, that although all the ſelect varieties may be multiplied plentifully by dividing the roots as directed below; yet it is neceſſary to raiſe a quantity of ſeedlings every two or three years, both to obtain new varieties, and to keep up a ſtock of young plants to ſucceed the old ones, which after the third year's bloom rarely flower ſo ſtrong and fair as the one or two years old ſeedlings.

It is proper likewiſe to continue increaſing the more excellent ſorts, by parting the roots.

By Parting the Roots.—By this method all the ſorts may be propagated in great abundance every year, for the roots multiply exceedingly by off-ſets into large bunches, ſo as to admit of ſlipping or parting annually in autumn; and every ſlip furniſhed with ſome fibres will readily grow, become a good plant, and flower the following ſpring; ſo that in the propagation by parting the roots any particular approved ſorts may be multiplied every year at pleaſure.

The proper time of year for this work is, any time in ſummer and beginning of autumn, after the plants have done flowering; but if performed in July or Auguſt, the ſlips will have good time to get ſtrength before winter, ſo as to flower ſtrong next ſpring.

At the proper time therefore take up the plants out of the ground, and divide each bunch into ſeveral ſlips, not too ſmall, unleſs where as great an increaſe as poſſible is wanted, being careful to preſerve ſome root to each ſlip, they are then to be planted in a freſh dug border, enriched with dung, ſetting them five or ſix inches aſunder, give water directly, and repeat it occaſionally till they have taken good root.

When a large quantity of theſe plants are required for ſale, or for the ſupply of markets, either the roots to plant, or the flowers for noſegays, a quantity ſhould be raiſed every year, both from ſeed and by ſlips as before obſerved, and planted out early in autumn, in beds or borders ſix inches aſunder; and after having one year's growth, they will be of a proper ſize for ſale.

Great quantities of the common ſorts are brought annually to Covent-garden and Newgate Markets every ſpring when in bloom for ſale, when they ſell for about a ſhilling per dozen of roots; though the fine ſorts are rarely brought to market, and they fetch a much greater price.

*Auricula Kinds.*

[2]PRIMULA *Auricula.*

*Auricula Urſi*, or *Bear's-ear*; *but commonly called Auricula.*] Hath a thick fibrated root, crowned by a cluſter of oblong, broad, fleſhy, ſerrated, ſmooth leaves, reſembling the ſhape of a bear's ear, and amidſt them upright flower-ſtalks from about three or four to ſix or eight inches high, terminated by an umbellate cluſter of beautiful flowers, of many different colours and variegations in the varieties.

It is a native of the Alps, but has been a long reſident of our gardens.

*Varieties of this.*] The varieties of this are amazingly numerous both in the diverſity of the leaves and flowers, ſuch as oblong-leaved—roundiſh-leaved—broad-leaved——narrow leaved——green-leaved——white or mealy-leaved, being covered with a fine mealy duſt or farina. And of flowers there are, purple-flowered, numerous ſorts of lighter or darker ſhades, ſtripes and variegations—red-flowered, numerous varieties of lighter or darker reds, ſtriped and variegated ſorts—yellow-flowered, ſeveral varieties, as bright yellows, buff-coloured, dun-coloured——double purple flowered, double yellow-flowered, variegated purples, and innumerable other moſt beautiful varieties. All the varieties, both ſelf coloured and variegated ſorts, have a circular eye in the middle of each flower, and

and of which there are, yellow eyed—white-eyed—and the petals of moſt of the ſorts are powdered with a moſt delicate farina, or mealy powder, which contributes exceedingly to the beauty of the flowers.

Of the above principal varieties there are innumerable diverſities, and many new ones annually acquired, which being all firſt obtained from ſeeds, though as the ſeedlings vary ſo greatly, it is probable that not one in a hundred may prove a real good flower; but when once any excellent new varieties are gained, they may be increaſed annually by off-ſets, to a large ſtock, and continued for ages; and the fine ſorts, according as they are obtained, are all named by the floriſts, ſometimes by that of the perſon who firſt raiſed them, but more frequently that of ſome illuſtrious perſonage, which they number and book accordingly.

They all flower in April and May, continuing a month or ſix weeks in beauty, and ripen plenty of ſeeds in June.

All the varieties are hardy, herbaceous, ever-green perennials, that proſper in any common ſoil of a garden not too wet in winter; for being ſomewhat ſucculent, a very humid ſoil in that ſeaſon is apt to rot them: allowing them however any moderately dry ſoil, they will ſtand all weathers the year round.

Conſidered as flowery plants, they claim precedence of moſt other ſpring flowers, for their admirable beauty and wonderful variety; and among floriſts are eſteemed the moſt beautiful of their prize and ſtage flowers, the fine ſorts being planted in pots, in order for placing them upon elevated covered ſtages or ſtands, during their bloom, both to ſhew the flowers to greater advantage, and to defend them from the full ſun and ſhowers of rain, which would impair their beauty, and haſten their decay: a ſhare of the common ſorts ſhould alſo be diſpoſed in the open borders in aſſemblage, or you may likewiſe plant a collection together in ſome bed or border to ſhew a general bloom; for they will proſper in any open ground, not under ſhade and drip of trees, &c. and are rarely injured by the moſt inclement weather.

But a quantity of the principal varieties with requiſite properties ſhould always be kept in pots, in order for moving to different ſituations for the advantage of blowing the flowers in the greateſt perfection.

The principal properties neceſſary to conſtitute a good Auricula are, the flower-ſtem ſhould be upright, tall, and ſtrong enough to ſupport its cluſter of flowers tolerably upright; the cluſter or truſs of flowers ſhould be large and regular, ſomewhat of a roundiſh form, all the florets of the bunch being ſuſtained on ſhort pedicles, in order to ſupport the whole in a proper poſition, to form the truſs cloſe and regular; the florets ſhould be large and the top ſpreading flat and regularly around, and the eye of each floret large, circular, and bright.

Flowers having nearly the above properties, being of fine colours, particularly the moſt beautiful variegated kinds, are proper ſorts to plant in pots (twenty-fours or thirty-twos) for ſtage flowers; ſo that when you raiſe ſeedlings, &c. you ſhould previouſly ſee them blow, to diſcover their properties before you pot them, which may be done early in autumn, when the flowering is paſt, planting one plant in each pot, and place them in the ſhade all ſummer, and in a warm ſituation in winter, and in ſpring, according as the flowers open, place them on ſome covered ſtage as before obſerved.

But in the culture of the fine varieties of Auriculas, the floriſts generally prepare a particular compoſt earth; the principal one is, light earth from ſome paſture ground, the top ſpit with the ſward, or any other good light mould, and neats dung or good rotten hot-bed dung, having of the earth and dung an equal portion of each, and about half the quantity of drift or ſea ſand; and ſometimes where rotten wood becomes earthy, ſuch as willow earth, old rotten tan, ſaw-duſt, &c. can be obtained, a portion is alſo added, mixing and forming the whole into an heap, to remain about a year, turning it over ſeveral times, and it will be of a proper temperature for uſe. See COMPOSTS.

In default however of the above mixtures, you may take any good light earth of a garden, blended with an equal portion of perfectly rotten dung, and a little drift ſand if poſſible.

*Their Propagation and general Culture.*

The method of propagating all theſe plants is by ſeed, to gain new varieties, and by ſlipping the roots to multiply the approved kinds.

By Seed.—By raiſing ſeedling plants we are ſure to gain ſome new varieties, and being raiſed one year, they begin to flower the next, though

though it is probable, that out of hundreds, there may be but very few real fine flowers; but when once any new excellent ſorts are ſo obtained, they multiply annually by off-ſets to increaſe the ſtock.

The ſeed generally ripens in June, and ſhould be ſowed in July or Auguſt, not later however than September; or it may be done in ſpring; but by ſowing early in autumn you gain time.

For this purpoſe get ſome large pots or boxes filled with light rich compoſt, ſow the ſeed on the ſurface, and cover it ſcarcely a ſtraw's breadth deep, and directly place the pots or boxes where they may have only the morning ſun during the hot weather, giving them moderate waterings, and if ſowed early in autumn, the ſeedlings will probably riſe in tolerable plenty the ſame year; in October, however, remove the pots, &c. to a warm ſunny ſituation for the winter, or may be placed in a garden-frame to have ſhelter from froſt, and exceſſive wet or ſnow; but let them enjoy the free air in all moderate weather; early in March replace them again in the ſhade to have only the morning ſun, for the quite young ſeedlings of theſe plants are unable to bear the ſun fully; therefore continue them in this ſituation all ſpring and ſummer, ſupplying them with water in dry weather; and in July following take opportunity of moiſt weather, and prick them out in nurſery-beds, or in large pots or boxes, filled with good compoſt; in either of which prick the ſeedlings pretty cloſe, *i. e.* two or three inches aſunder, giving water and occaſional ſhade from the ſun till freſh rooted, or if in pots or boxes, remove them to a ſhady ſituation: in theſe beds or pots, &c. they are to remain till they flower, which will be ſpring following, when all the good ſorts ſhould be marked, or may be directly tranſplanted into ſeparate ſmall pots (twenty-fours) one plant in each; and next year they will all blow in perfection, and diſcover their properties more perfectly, then may be ſhifted into larger pots (thirty-twos); obſerving to manage them as hereafter directed.

The ordinary ſorts will do to plant in the common borders, to form variety amongſt other low ſpring flowers.

By Off-ſets, or dividing the Roots.—By this method all the ſelect varieties are propagated, for the roots throw out off-ſets in tolerable plenty, each of which being ſlipped off and planted, will next ſpring produce flowers exactly like the parent plant, and theſe in their turn produce off-ſets for further propagation, which will produce alſo the ſame ſort of flowers, &c. and thus may the choice varieties be annually increaſed, and continued for years.

The ſeaſon for performing this work is, occaſionally both in ſpring and autumn; if only to ſlip off any outſide off-ſets that appear, it may be done in ſpring, either before or at the time of flowering, though towards autumn, about July or Auguſt, when the flowering ſeaſon is paſt, and the plants having had the ſpring and ſummer's growth to furniſh ſtrong off-ſets, will be the moſt eligible ſeaſon for any general propagation by ſlips: the roots may be then either taken up and divided into ſeveral ſlips, where a conſiderable increaſe is required, or the roots may ſtand, and only detach any outſide off-ſets, as aforeſaid; and in either ſeaſon or method of ſlipping or dividing the plants, proceed to pot the off-ſets or ſlips of the choice ſorts ſeparately, but the common kinds may be planted in beds of rich earth.

Having however ſlipped or divided the off-ſets of the fine varieties, then being furniſhed with a quantity of ſmall pots, twenty-fours or thirty-twos, according to the ſize of the ſlips, filling them with the proper compoſt, plant one off-ſet in each pot; give ſome water to ſettle the earth, and promote their ſtriking; and then place them under ſome ſhady fence, upon level clean ground, to have only the morning ſun all ſummer, repeating the waterings in dry weather two or three times a week; and at the approach of winter place them under ſome warm wall open to the ſun, to remain until ſpring, and begin to ſhew their flowers, when the choice ſorts ſhould be placed on the Auricula ſtage, in order to protect the bloom from the weather, and preſerve them as long as poſſible in beauty.

*General Management.*

In the culture of the fine Auriculas in pots, it is proper, as before hinted, to have ſome ſort of covered ſtage, having the front open to the morning ſun only, on which to arrange the pots of plants when in bloom, to ſhew the flowers to good advantage, and protect them from rain and too much ſun: the ſtage ſhould have ſeveral ranges of narrow ſhelves, one above another, on which to ſet the pots; ſome ſtages are ſo conſtructed as to turn round any way at pleaſure, more or leſs to the ſun; and

ſome

ſome are formed circular, having the ſhelves arranging in a pyramidal manner, and ſome have canvas curtains to draw or let down occaſionally, either to break off driving rains, or afford ſhade from the ſun.

On theſe ſtages the pots of plants ſhould be placed in the ſpring, according as the flowers of each plant begins to open, and not before, to remain during the continuance of the beauty of the flowers; obſerving to ſupply them with water about three times a week, or every other morning, giving it only to the earth in the pots, at leaſt let none fall on the flowers, for wet would greatly deface the bloom.

When the full blow is paſt, remove the pots directly into the full air in a ſhady border to receive the full benefit of the free air and rains, to encourage their off-ſets and the ripening of ſeeds.

During the ſummer ſeaſon they ſhould remain conſtantly in the ſhade, but not under drip of trees, and muſt have proper waterings in dry weather.

In July or Auguſt the plants ſhould be freſh potted into new compoſt, but more eſpecially ſuch plants as have thrown out ſome good off-ſets, ſhould have them ſeparated and potted as already directed; though ſmall plants that have made no progreſs in off-ſets, may remain unremoved another year; obſerving, however, that July or the beginning of Auguſt is the beſt time for freſh potting them, ſtill continuing them in the ſhade during the hot weather, and ſupply them with water.

At the approach of winter remove the pots under ſome warm ſituation open to the ſun, to remain till ſpring, or may be placed under ſome hoop-arches, or in a garden frame, and there occaſionally ſheltered from ſevere froſt, great rains, and ſnow, to preſerve them in greater vigour, but muſt conſtantly enjoy the full air in all mild weather; in default, however, of ſuch ſhelters, arrange the pots cloſe along under a warm wall, for the plants are very hardy, only obſerving, that when very wet or ſnowy weather begins, lay the pots down on one ſide with the plants towards the ſun, to prevent their receiving too much moiſture, which would rot theſe kind of plants; but as the ſpring advances, place them upright again, that the flower-bud may take its proper upright direction.

In ſpring, about the beginning or middle of February, it is proper to mould up the pots with ſome freſh compoſt; firſt take out ſome of the old mould at a convenient depth without diſturbing the roots and clear the plants from any decayed leaves, then immediately fill up the pots with new earth: this will prove a very beneficial dreſſing both in ſtrengthening the bloom and encouraging the growth of off ſets.

When the plants begin to ſhew their flower-buds, occaſional ſhelter, if ſharp froſts happen, will be of great ſervice in preſerving them from being blighted, which often prevents their blooming fair, and ſometimes intirely deſtroys the flower; it is therefore adviſable to uſe a ſlight covering of mats every froſty or very cold night about the firſt ſhooting of the buds.

And according as the flowers open fairly remove the pots on the ſtage, &c. to remain to blow as already directed.

The further management of the potted plants after flowering is the ſame as before, and which is to be repeated every year.

[3]PRIMULA *Farinoſa.*

*Farinoſous Primula, commonly called Bird's-eye.*] Hath a fibrous root, with a ſmall ſcaly head, crowned by ſeveral long, ſmooth, crenated leaves, mealy underneath, and upright flower ſtalks half a foot high, terminated by a cluſter of ſmall red flowers, having yellow eyes in the center.

It grows naturally in the North, but is cultivated in many gardens as a flowing plant; produces its flowers in the ſpring.

Plant it in any common border, it will flower annually and multiply plentifully by off-ſets.

PRINOS Winterberry.

Two ſhrubby ſpecies compoſe this genus, one is deciduous the others an ever-green, both hardy ſhrubs for the ſhrubbery, &c. obtain eight or ten feet ſtature, garniſhed with oblong leaves, and menopetalous wheel-ſhaped flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, is monophyllous, ſix parted and permanent. COROLLA, is one wheel-ſhaped petal cut into ſix oval ſegments. STAMINA, ſix awl ſhaped ſhort filaments and oblong obtuſe antheræ. PISTILLUM, an oval germen terminating in a ſhort ſtyle, and obtuſe ſtigma. PERICARPIUM, a roundiſh ſex-locular berry, having ſix hard ſeeds.

The ſpecies are,

[1]*Prinos Verticillatus,* (deciduous)

*Virginia deciduous Winterberry.*] Grows ſix or eight feet high, very branchy from bottom to top; large ſpear-ſhaped longitudinally-ſawed leaves placed alternately, and ſmall flowers from the ſides of the branches, ſome ſingly, others two or three together, ſucceeded by purple berries remaining all winter.

2 PINOS *Glaber* (ever-green.)

*Smooth Ever-green Canada, Winterberry, Yappon, or South-Sea Thea Shrub.*] Grows eight or ten feet high, branchy quite from the bottom, oblong ſpear-ſhaped leaves ſerrated at the top, placed alternately, and at the axillas ſmall flowers two or three together, ſucceeded by purpliſh berries continuing all the winter.

Both theſe ſhrubs are of America, are tolerably hardy, eſpecially the deciduous kind, and have been long in our gardens as ornamental ſhrubs to encreaſe the collection in the ſhrubbery, &c.

But the ever-green kind being of a more tender nature, it is alſo kept in pots in order to be wintered in a green-houſe.

They are propagated moſtly by ſeed ſowed ſoon after they are ripe or early in ſpring, in a bed of light earth, covering them full half an inch deep, ſome of which will probably come up the firſt ſpring, but if not ſowed till the ſpring they often remain in the ground till the ſpring following, unleſs forwarded in a hot-bed: when the plants are one or two years old they ſhould be planted out in nurſery rows; it will alſo be proper to plant ſome of the ever-green kind in pots to have occaſional ſhelter the firſt two or three winters as being rather ſomewhat tender whilſt young; but when they have gathered ſtrength turn ſome of them out into the full ground, and retain ſome in pots as green-houſe plants.

## PRUNING.

Pruning is an operation of the knife performed upon trees occaſionally, in order both to give them any deſired form, and to retrench or reduce irregular and redundant or ſuperfluous growths, or whatever creates confuſion and diſorder.

But this operation is particularly neceſſary to be practiſed on many ſorts of fruit-trees, more eſpecially the dwarf ſorts, ſuch as all kinds of wall and eſpalier fruit-trees; it is alſo neceſſary to be performed occaſionally upon ſtandard trees, both dwarfs and half and full ſtandards, to all of which proper Pruning is neceſſary; ſome ſorts annually, as all kinds of wall trees, eſpaliers, and moſt other dwarf or trained fruit-trees; which being requiſite in order to preſerve the proper figure, and to keep them within their limited bounds, as well as to promote fruitfulneſs; but as to common ſtandards whoſe heads having full ſcope of growth every way, they require but very little Pruning, except juſt to retrench any occaſional redundancy, ill-growing branch, and dead wood. Wall trees and eſpaliers however, require a general regulation of Pruning twice every year, in ſummer to retrench the evidently ſuperfluous and ill-placed ſhoots of the year, and to train in a ſupply of the moſt regular ones; and in winter to give a general regulation both to the ſupply of young wood left in ſummer and to the old branches where neceſſary.

For in Pruning wall trees and eſpaliers it is to be obſerved, that as theſe trees having their branches arranged with great regularity to the right and left one above another parallelly, about five or ſix inches aſunder, forming a regular ſpread, ſo as the branches of each tree completely covers a certain ſpace of walling, &c. and as the whole ſpread of branches conſtantly ſend forth every year a great number of unneceſſary and uſeleſs ſhoots; and that as each tree being limited to a certain ſpace, as juſt obſerved, an annual pruning is conſequently moſt neceſſary to retrench the redundancies, and all irregular and bad ſhoots to give the proper bearing branches due room, as well as to enable us to confine each tree within its allotted limits, conſiſtent with its regular form.

The firſt Pruning neceſſary for fruit-trees, is when we attempt to give the head its firſt regular formation, effected by Pruning ſhort or heading down in ſpring all the ſhoots produced the firſt year from budding and grafting, that is, the firſt ſhoots from the budding, &c. when a year old being generally pruned down in March, within four or five eyes of the bottom, whereby it throws all the ſap into the remaining lower buds, and thus, inſtead of running up to one ſtem, it puſhes forth ſeveral ſtrong ſhoots from the lower part the enſuing ſummer ſo as to fill the allotted ſpace of wal ing and eſpalier regularly quite from the bottom; which ſhoots being trained ſtrait and regular in a ſpreading manner, each at full length all ſummer; and in winter or ſpring following, if a ſupply of more principal ſhoots ſhall ſeem neceſſary to form the head more effectually

tually, prune ſhort alſo theſe ſhoots each to four or five eyes, and each of them will throw out the like number of ſhoots the ſame year, which, according as they advance in length, train at regular diſtances at full length during the ſummer as before obſerved, for the ſhoots of wall trees ſhould never be ſhortened in the ſummer ſeaſon, for this would cauſe them to puſh forth many trifling lateral ſhoots; though ſometimes, in order to fill a vacancy as ſoon as poſſible, ſtrong young ſhoots being pinched early in the ſeaſon, as in May or beginning of June, to four or five eyes, will throw out ſeveral proper ſhoots the ſame ſummer, repeating however the work of Pruning ſhort occaſionally one or two years, &c. as above, either in general or to particular ſhoots as it may ſeem proper till a proper ſet of branches are by that means obtained to give the head of the tree a proper formation; afterwards Pruning ſhort is to be omitted except occaſionally to any particular ſhoot to fill a vacant ſpace: but ſome ſorts of wall trees require almoſt a general ſhortening of their ſupply of ſhoots, ſuch as peach, nectarines, &c. which bear only on the young wood; have that of each year ſhortened, to force out a ſupply of ſhoots for future bearing: other ſorts of wall-trees and eſpaliers are not in the general courſe of pruning to be ſhortened, ſuch as pears, apples, plums, and cherries, which bear in the old wood from two or three to many years growth. See DWARF TREES and ESPALIERS.

After the trees are thus furniſhed with a proper ſpread of branches trained regularly to the wall and eſpalier, they will every year throw out many more ſhoots than are wanted, or can be converted to uſe, by being ſome too numerous, others ill placed, aud others of a bad growth, all of which muſt therefore be regulated accordingly by proper pruning, for as the regular figure of the tree, well furniſhed in every part equally from the bottom to the top of the wall or eſpalier with proper branches, capable of producing a reaſonable quantity of good fruit, are the principal objects of Pruning, all our operations muſt be directed to theſe ends.

We muſt therefore be careful to eaſe the trees of every thing that is either ſuperfluous, irregular, or hurtful, by Pruning twice every year, a ſummer and a winter Pruning. We call that ſuperfluous which though good and well placed, yet are more than are wanted or can be properly laid in, and that irregular which is ſo ill placed as it cannot be trained with regularity to the wall or eſpalier, ſuch as all fore-right ſhoots, being ſuch as grow immediately from the front or back of the branches in a fore-right direction, which though good of themſelves, yet their ſituation renders them irregular or unfit for training; and we call that hurtful which is in itſelf of bad growth, ſuch as all very rank or ſingularly luxuriant rude ſhoots; ſo that the ſuperfluous or redundant growths ſhould be thinned by Pruning out all that ſeem to cauſe confuſion, and the irregular and hurtful rank ſhoots ſhould be diſplaced, cutting every thing of all theſe ſorts off quite cloſe to the place from whence they proceed, leaving however a proper ſupply, more or leſs, of the regular or beſt placed ſide-ſhoots where neceſſary, ſo as to preſerve every part well furniſhed with bearing wood, trained ſtraight and cloſe to the wall or eſpalier at equal diſtances; obſerving ſome ſort of wall-trees, &c. require a general annual ſupply of young wood, ſuch as peach and all other trees which bear only on the ſhoots of a year old; others require only an occaſional ſupply of wood, ſuch as apples, pears, &c. and all other kinds that bear on the old wood of from two or three to ten or twenty years old or more, ſo that the ſame branches continuing in bearing many years, the trees require only a ſupply of young ſhoots now and then to replace any worn out and dead branches. See *Summer* and *Winter Pruning*.

For the myſtery of Pruning conſiſts in being well acquainted with the nature of bearing of the different ſorts of trees, and forming an early judgment of the future event of ſhoots and branches, and many other circumſtances, for which ſome principal rules may be given; but there are particular inſtances which cannot be judged of but upon the ſpot, and depends chiefly upon practice and obſervation.

The nature or mode of bearing of the different ſorts of wall and eſpalier trees, &c. is materially to be conſidered in Pruning.

For example, peaches, nectarines, apricots, &c. all produce their fruit principally upon the young wood of a year old, that is, the ſhoots produced this year bear the fruit the year following, and the ſame of every year's ſhoots, ſo that conſequently, in all theſe trees, a general ſupply of the beſt regular ſhoots of each year muſt be every where preſerved at regular diſtances quite from the very bottom to the extremity of the tree on every ſide in ſuch order as to ſeem coming

up regularly one after another, which being trained principally all at full length all ſummer: but in winter Pruning, a general ſhortening leſs or more, according to the ſtrength of the different ſhoots, is neceſſary in order to prombte their throwing out more effectually a ſupply of young wood the enſuing ſummer, in proper places for training in for next year's bearing, the fruit being generally produced all along their ſides immediately from the eyes, they rarely forming any conſiderable fruit-ſpurs, as in the apple, pear, &c. but the ſame ſhoots both produce the fruit and a ſupply of ſhoots at the ſame time for the ſucceeding year's bearing.

Vines alſo produce their fruit always upon the young wood, ſhoots of the ſame year ariſing from the eyes of the laſt year's wood only, and muſt therefore have a general ſupply of the beſt regular ſhoots of each year, trained in, which in winter Pruning muſt be ſhortened to a few eyes in order to force out ſhoots from their lower parts only, properly ſituated to lay in for bearing the following year.

Figs bear alſo only upon the young wood of a year old, and a general ſupply of it is therefore neceſſary every year; but theſe ſhoots muſt at no time be ſhortened, unleſs the ends are dead, becauſe they always bear principally towards the extreme part of the ſhoots, which if ſhortened would take the bearing or fruitful parts away: beſides, theſe trees for the general part naturally throw out a ſufficient ſupply of ſhoots every year for future bearing without the precaution of ſhortening.

And as to apple, pear, plum, and cherry trees, they generally bear principally on ſpurs ariſing in the wood of from two or three to ten or twenty years old, the ſame branches and ſpurs continuing bearing a great number of years, ſo that having once procured a proper ſet of branches, in the manner already directed, to form a ſpreading head, no farther ſupply of wood is wanted than only ſome occaſional ſhoots now and then to ſupply the place of any worn-out or dead branch as before hinted; the abovementioned ſpurs or fruit-buds are ſhort robuſt ſhoots, of from about half an inch to one or two inches long, ariſing naturally in theſe trees, firſt towards the extreme parts of the branches of two or three years old, and as the branch encreaſes in length the number of fruit-buds encreaſe likewiſe accordingly; this therefore determines, that in the general courſe of Pruning all theſe kind of trees, their branches that are trained in for bearing muſt not be pruned or ſhortened but trained at full length; for if they were ſhortened it would diveſt them of the very parts where fruit-buds would have firſt appeared, and inſtead thereof, would throw out a number of ſtrong unneceſſary wood-ſhoots, from all the remaining eyes; therefore let all the ſhoots or branches of theſe trees be trained principally at full length, and as they advance ſtill continue them entire, thus they will all readily form the afore mentioned little ſpurs or fruit-buds from almoſt every eye; when indeed there is a vacancy, and there is only one ſhoot, where two or three may be requiſite, in which caſe only pruning or ſhortening is allowable in theſe trees, to force out the ſupply required. See the different ſorts under their proper *genera*, alſo the article DWARF-TREES.

In theſe trees great care is neceſſary to preſerve all the proper fruit-buds or ſpurs, which are readily diſtinguiſhed by their ſhort, thick, robuſt growth rarely exceeding one or two inches long.

In the general courſe of Pruning all ſorts of wall and eſpalier trees, that when diſplacing the ſuperfluous and ill placed woods, &c. always take them off quite cloſe both in the ſummer and winter Pruning, not leaving any ſpurs or ſtumps of them an inch or two long, as often done, which fills the tree full of diſagreeable ſtumps, and which puſhing out ſtrongly from every eye, crowds the tree with a multitude of unneceſſary and irregular ſhoots, and cauſes great confuſion and obſcurity, and exhauſts the ſap to no purpoſe, as well as occaſions a great deal of labour to retrench them; remember therefore, that all ſhoots and branches neceſſary to be retrenched muſt be taken off quite cloſe to the place from whence they ariſe; which in the ſummer Pruning if attended to early, while the ſhoots are quite young and tender, they may readily be rubbed off quite cloſe with the thumb; but when the ſhoots become older and woody, as they will not readily break, it muſt be done with a knife, cutting them as cloſe as poſſible, and all winter Pruning muſt always be performed with a knife.

It ſhould alſo generally be obſerved in Pruning in ſummer, that all the neceſſary ſupply of regular ſhoots that are left for training in ſhould never be ſhortened during

ing

ing this ſeaſon, unleſs to particular ſhoots to fill a vacancy for by a general ſhortening in this ſeaſon, all the ſhoots ſo treated would ſoon puſh again vigouroufly from every eye, and run your trees into a perfect thicket of uſeleſs wood; therefore all ſorts whether they require ſhortening in the winter Pruning or not, ſhould, in the ſummer dreſſing, be layed in at full length.

Two ſeaſons of pruning are requiſite for all ſorts of wall and eſpalier trees, a ſummer and a winter Pruning.

Summer Pruning.—The ſummer Pruning is a moſt neceſſary operation; every one muſt know that in ſpring and ſummer wall and eſpalier trees abound with a great number of young ſhoots that require thinning and other reforms to preſerve the beauty of the trees and encourage the fruit, and the ſooner it is performed the better; it is therefore adviſable to begin this work in May or early in June, and timely diſburthen the trees of all evidently redundant or ſuperfluous growth and ill placed and bad ſhoots, which may be performed with conſiderably more expedition and exactneſs than when after the trees have ſhot a conſiderable length and run into confuſion and diſorder by their ſhoots forming a thicket, when it will in a manner be impoſſible to ſee what you are about; beſides the diſadvantage of choaking up the fruit behind ſuch a thicket of wood and leaves: it is therefore of great importance to perform this operation in the month of May or early in June, or when the ſame year's ſhoots are ſufficiently formed to enable you to make a proper choice, and tender enough as to require no other inſtrument than the thumb to diſplace the bad growths and ſuperfluities.

However, at any rate, let the work of ſummer Pruning be began before the trees have ſo far advanced in ſhooting as to cauſe much confuſion, which would coſt you a great deal of pains, precaution, and perplexity, to penetrate and break through the obſcurity to determine what is proper to retrench or what to leave.

In this Pruning, we obſerved above, that a great many more ſhoots ariſe from all the principal branches than are wanted, or that can poſſibly be trained with regularity, or that are well placed or proper for the purpoſe; our buſineſs therefore now is to thin and regulate them, by pruning away the ſuperfluous ſhoots, and all ſuch as are ill placed and of bad growth as aforeſaid: as to ſuperfluous ſhoots they are to be conſidered as ſuch when any tree throws out a redundancy of wood, or much more than what is wanted, or that can be trained in; of theſe you muſt now retrench the moſt irregular placed, weakeſt, and all ſuch as are evidently not wanted for uſe, and where two or more ſhoots any where ariſe from the ſame eye, clear all away but one of the beſt, reſerving a ſufficiency of the moderately ſtrong and moſt regular placed ſide ſhoots, and always a leading one at the end of every branch, all of which to be trained in to chuſe from in the winter Pruning, leaving more or leſs in proportion, according to what the trees are, or the mode of bearing as before hinted; though in all thoſe trees that bear always on the young wood leave rather more ſhoots at preſent than what may appear juſt neceſſary, eſpecially of peaches, nectarines, apricots, vines, figs, &c. for it is highly requiſite to reſerve regular wood enough in the ſummer to chuſe out of in winter Pruning to lay in for next year's bearing; but as to apples, pears, plums, cherries, &c. which continue bearing many years on the ſame branches, ſhould leave only here and there ſome good ſhoots towards the lower parts or in any vacancy till winter, and if then not wanted they are eaſily retrenched. Ill placed ſhoots being ſuch as either grow directly from the front or back of the branches ſtraight fore-right, (called fore-right ſhoots,) or any other ways ſo ill placed as not to admit of training with regularity, ſo muſt all be cut out quite cloſe; and bad or hurtful growth being conſidered as any very luxuriant ſhoots, diſtinguiſhed from the others by their rank, vigorous ſhooting, and are like to prove injurious by drawing all the nouriſhment, and impoveriſhing the neighbouring ones that are of more moderate growth, ſhould generally be removed, except where any may ſeem proper to leave to fill a vacant ſpace, in which it may be pinched early to three or four eyes, when it will furniſh you with the like number of more moderate ſhoots to fill the vacancy.

Where however a tree is in general inclined to luxuriancy, it is proper to retain as many of the regular ſhoots as can be commodiouſly trained in with any regularity, in order to divide and exhauſt the too abundant ſap which cauſes the luxuriancy; for by humouring ſomewhat the natural inclination of

luxuriant

luxuriant trees by leaving plenty of branches and theſe moſtly at full length, is the only method by which we can the moſt readily reduce them to a more moderate ſtate of growth.

Pay particular attention always to the lower parts of your trees, for frequently we ſhall find proper ſhoots ariſing in places neceſſary to be trained in, either to ſupply a preſent or an apparent future vacancy, or as a reſerve to replace any decayed or worn out or other bad branch, ſo that if moderately ſtrong well placed ſhoots arife in ſuch parts, they are particularly to be regarded at this time; and in winter Pruning ſuch of them as are not wanted may be eaſily cut out.

All weak trifling ſhoots ſhould now alſo be taken out, unleſs any ſhall appear uſeful to fill a vacancy, or likely to be of ſervice hereafter.

Obſerve in this Pruning not to diſturb the natural fruit-buds or ſpurs, before deſcribed.

After having ſummer Pruned and cleared any tree from all uſeleſs ſhoots as above, let all the remaining proper ſhoots be directly, or as ſoon as they are long enough, trained in ſtraight and cloſe to the wall or eſpaliers and all of them at full length during the ſummer ſeaſon, for the reaſons before given; not ſhortening any at this time except as before obſerved, when there is any great vacancy, when pinching to three or four eyes may be proper; but let all the reſt be trained at full length till winter Pruning, when they muſt undergo another regulation and ſhorten thoſe of ſuch trees as require it, as peach, nectarine, &c.

The work of training in the ſhoots in this ſeaſon is, if againſt walls, both by nailing by means of proper ſhred and nails, and occaſionally by faſtening in the ſmaller ſhoots, with little ſticks or twigs ſtuck between the main branches and the wall; and for eſpaliers tie them with ſmall oziers, ruſhes, or baſs ſtrings.

Having thus ſummer dreſſed and trained your trees, it will be neceſſary to review them occaſionally, in order to reform ſuch branches or ſhoots as may have ſtarted from their places or taken a wrong direction, alſo that according as any freſh irregular ſhoots produced ſince the general dreſſing may be diſplaced; and likewiſe as the already trained ſhoots advance in length or project from the wall or eſpalier, they ſhould be trained in cloſe, ſtill continuing them at full length during their ſummer's growth, for every thing ſhould be kept cloſe and regular all ſummer, whereby your trees will appear beautiful to the eye, and the fruit will ſhew itſelf and attain its due perfection.

For by thus properly ſummer Pruning and training wall and eſpalier trees early in the ſummer, you preſerve their regularity and proſperity, and by clearing out all the unneceſſary and uſeleſs growths, training the reſt cloſe and regular, the fruit will receive all requiſite advantage from the ſun, air, rains, &c. and it will of courſe attain the greater perfection both in ſize, beauty, and flavour.

Winter Pruning.—In the winter Pruning a general regulation muſt be obſerved both of the mother branches and the ſupply of young wood laid in the preceding ſummer, and the proper time for this work is any time in open weather from the fall of the leaf in November until March.

In performing this work of winter Pruning, it is proper to unnail or looſen great part of the branches, particularly of peaches, nectarines, apricots, vines, and ſuch other trees, as require an annual ſupply of young wood.

Firſt look over all the principal or mother branches, and examine if any are worn out or not furniſhed with parts proper for bearing fruit, according to the rules before illuſtrated with reſpect to the nature of bearing of the different ſorts of trees; and let ſuch branches be cut down to the great branch from which they proceed, or to any lower ſhoot or good branch they may ſupport toward their bottom part, leaving theſe to ſupply its place; likewiſe examine if any branches are become too long for the allotted ſpace either at ſides or top, and let them be reformed accordingly by ſhortening them down to ſome lower ſhoot or branch properly ſituated to ſupply the place, being careful that every branch terminates in a young ſhoot of ſome ſort for a leader, and not ſtumped off at the extremity, as is too often practiſed by unſkilful pruners.

From the principal or larger branches paſs to the ſhoots of the year, which were trained up in ſummer, firſt cutting out cloſe all foreright and other irregular ſhoots that may have been omitted in the ſummer Pruning; likewiſe all very weak ſhoots, and thoſe of very luxuriant growth, unleſs it be neceſſary to keep ſome to ſupply a vacant place; then of the remaining regular ſhoots, you are to ſelect a greater or ſmaller portion to leave either as a general ſupply for next year's bearing as in the caſe for peach, nectarine,

tarine, apricots, vines, and figs; or only ſome occaſional ſhoots, as in apples, pear, plum, and cherry trees, to ſupply the place of any bad or dead branch.

But as peach, nectarines, apricots, vines, and figs, always bear principally on the year-old wood as before noticed, a general ſupply of young ſhoots muſt be left in every part from bottom to top at regular diſtances, all of which, except the fig, muſt be more or leſs ſhortened according to their ſituation and ſtrength to encourage their furniſhing more readily a proper ſupply of ſhoots in ſpring and ſummer for next year's bearing, as before obſerved, leaving the ſtrongeſt ſhoots always the longeſt, as is more fully explained under each of their reſpective *genera*; but as the figs always bear towards the end of the ſhoots they muſt not be ſhortened.

And with reſpect to the apples, pears, plums, cherries, &c. as they continue to bear on the old branches of from two or three to many years ſtanding, they only require an occaſional ſupply of young wood, according as the branches become unfit for bearing and want removing, ſo ſhould accordingly train in here and there in proper places ſome good regular young ſhoots towards the lower part, to be coming gradually forward to a bearing ſtate, to be ready to replace worn out and other uſeleſs branches; and what ſhoots are not now wanted for that purpoſe cut them out cloſe, not leaving any ſpur or ſtump, as every one of which, as we before obſerved, would puſh out ſeveral ſtrong unneceſſary ſhoots the next ſpring to the prejudice both of the trees and fruit: have particular regard to preſerve the ſhoots at the termination of all the already trained branches entire, not however ſuffer more than one ſhoot to terminate each branch; preſerve alſo carefully all the proper fruit-ſpurs; likewiſe obſerve, that the ſupply of young wood occaſionally reſerved, and the branches in general of theſe trees, ſhould all be trained in at full length, and continued ſo in future, as far as the limited ſpace will admit, and according as any extend above the wall or eſpalier or any where beyond their proper limits, they ſhould be pruned down with diſcretion to ſome convenient bud, or lateral ſhoot, or lower branch, which train alſo entire.

In this Pruning, as in the ſummer dreſſing, it is of importance to have a ſtrict eye to the lower parts of wall-trees, &c. to ſee if there is any preſent vacancy or any that apparently will ſoon happen, in which caſes, if any good ſhoot is ſituated contiguous, it ſhould be trained in either at full length, or ſhorten it to a few eyes to force out two or more ſhoots if they ſhall ſeem neceſſary; for precaution ſhould ever be obſerved in taking care to have betimes a ſufficient ſtock of young wood coming forward to fill up any caſual vacancy, and ſubſtitute a new ſet of branches in place of ſuch as are either decayed or ſtand in need of retrenchment.

Sometimes in wall-trees and eſpaliers there are many large diſagreeable barren ſpurs, conſiſting both of old worn-out fruit-ſpurs, and of cluſters of ſtumps of ſhortened ſhoots projecting conſiderably from the branches, occaſioned by unſkilful Pruning when retrenching the ſuperabundant and irregular ſhoots, which inſtead of being cut out cloſe, are ſtumped off to an inch or two long, and in the courſe of a few years, forming numerous barren ſtumps, as above ſaid, and very little fruit, the trees appear like a ſtumped hedge; it is therefore, in this ſeaſon of Pruning, adviſable to reform them as well as poſſible by cutting all the moſt diſagreeable ſtumps clean out cloſe to the branches, leaving theſe at full length, eſpecially of apples, pears, &c. as before adviſed; and reſerve an occaſional ſupply of young wood in different parts, and thus in two or three years you may reduce ſuch trees to a regular figure and a proper ſtate of bearing.

Bad Pruning ruins many a good tree, as is obſervable in numerous gardens, where the wall trees and eſpaliers appear as juſt above deſcribed, pruned every year, yet never produce any tolerable crop of fruit.

The reaſon is, the operation or art of Pruning is much more generally practiſed than underſtood; different pruners have different ideas of Pruning: many proceed upon little or no principle, and often prune all trees alike, and their idea of Pruning often conſiſts in retrenching annually moſt of the young ſhoots, and ſhorten all the branches of every tree without exception to the great injury of ſome ſorts, and retarding their bearing: likewiſe many pruners in retrenching the ſuperfluous and irregular ſhoots, inſtead of cutting cloſe, as formerly obſerved, they often ſtump them off to about one or two inches long; theſe remaining ſtumps ſhoot out again from every eye, and fills the tree with more numerous uſeleſs ſhoots than before, which being alſo pruned down to ſtumps of an inch or two long, as above, practiſing the ſame every Pruning, ſo as in the

the courſe of a few years every branch is loaded with cluſters of large rugged barren ſpurs, formed wholly of the ſtumps of ſhortened ſhoots, occupying the places where fruit-buds might be expected: it is alſo obſervable, that many pruners think every branch of all ſorts of wall trees whatſoever muſt in the annual Pruning undergo the diſcipline of the knife, ſo ſhorten all without diſtinction and reluctance, often too with ſo much ſeverity on trees that ſhould not be ſhortened, as to deſtroy the very parts where fruit-buds would have been produced, they thinking this general ſhortening neceſſary to ſtrengthen the branches, which, however, in many ſorts, promotes a too vigorous growth, particularly in trees that produce their fruit on natural ſpurs, forming themſelves gradually all along the ſides of the branches, firſt towards the extreme parts, that ſhortening not only cuts off theſe firſt fruitful parts of the branches, but throws the ſap back with ſo much vigour to the remaining buds, that inſtead of forming fruit-ſpurs almoſt every bud puſhes out luxuriant ſhoots, and the trees are continually crowded with unneceſſary wood, cauſing a great annual trouble to retrench it, without the pleaſure of having a quarter of a crop of fruit: beſides the annually cutting out ſo much ſtrong wood is very prejudicial to ſome ſorts of fruit-trees.

Too ſevere Pruning is greatly prejudicial to the health of ſome ſorts of ſtone fruit-trees, in particular, by cauſing them to gum and ſoon decay.

Plums and cherries, in particular, are often greatly damaged by a too ſevere diſcipline of the knife, theſe trees being very liable to gum by large amputations, it is therefore of importance to attend to theſe trees well in the ſummer Pruning, to retrench all the ſuperfluous and irregular ſhoots betimes in the ſummer while quite young, and pinch others occaſionally where wood is wanted to fill vacancies, ſo as to require but little Pruning out of large wood in winter.

But if our former hints in the ſummer and winter Pruning are attended to in retrenching the uſeleſs wood every year at the time adviſed, you will always preſerve your trees free from all incumbrance and every part will be regularly filled with bearing wood, and their general management will prove eaſy.

A general nailing, &c. muſt every year be performed according as we advance with the Pruning.

Therefore it is proper that every tree as ſoon as pruned be directly nailed to the wall, or if eſpaliers, tie them to the treilage; obſerving, that in the winter Pruning, as the work of nailing, &c. will require to be performed more or leſs upon all the branches, we muſt be careful to train them with great regularity, nailing them along horizontally, as ſtraight and cloſe as poſſible, never croſs any of the branches, but train them diſtinct and parallel five or ſix inches aſunder, as formerly adviſed, or in proportion to the ſize of the leaves and fruit of the different ſorts, making the oppoſite branches of each ſide arrange equally in the ſame poſition.

Thus far is principally all we have to advance reſpecting the general mode of Pruning wall and eſpalier trees; particulars for each ſort being noticed more fully under their proper *genera*; but what we have here advanced under this article *Pruning* is to convey ſome general hints to unexperienced pruners, though there are many expedients and reſources, not to be diſcovered but by repeated practice.

### *Pruning Standards.*

Standard fruit-trees require but very little Pruning, for as their branches having full ſcope to extend themſelves every way, they muſt not be ſhortened; beſides, as our ſtandard fruit-trees, conſiſting principally of apples, pears, plums, and cherries, which, as before ſaid, bear fruit on natural ſpurs ariſing towards the upper parts of the branches, which, as obſerved in the wall-tree and eſpalier Pruning, determines that we muſt not ſhorten them, nor practiſe any other Pruning than juſt to reform any great irregularity, &c.

The firſt occaſional Pruning however, neceſſary for ſtandard fruit-trees is the firſt two years of their growth, in order to form their heads ſomewhat regular, by retrenching any irregular ſhoots, and when deſigned to have them form more regular ſpreading heads, it is cuſtomary to prune the firſt ſhoots when a year old down to four or five eyes, in order to force out lateral ſhoots from theſe lower buds the following ſummer, to give the head a proper formation. After this ſuffer the branches to take their natural growth, ex-

cept that, if while the trees are young, any very luxuriant ſhoots ramble away conſiderably from all the others, and draw moſt of the nouriſhment, it is proper to prune them, either by retrenching entirely very irregular ones, or ſhorten others more or leſs, ſo as to cauſe them to branch out conſiſtent with the requiſite form of the head.

But let it be remarked in general, that except in ſuch caſes of reducing irregularities, let the heads of all kinds of ſtandards always branch away as faſt as poſſible, both in length and laterally, agreeable to their natural mode of growing; and they will naturally furniſh themſelves abundantly with bearing wood.

Obſerve however, that as in ſtandard trees of ſome years growth, irregularities and diſorder will occaſionally happen, which ſhould be regulated a little by Pruning the moſt conſpicuouſly irregular and redundant growths; performing it always in winter.

For inſtance; where any branch grows right acroſs others, or in any other aukward direction, to incommode or cauſe confuſion in the head, it ſhould be retrenched cloſe; likewiſe any branch that rambles conſiderably from all the reſt, ſhould be reduced to order, by cutting it down to ſome convenient lower branch, ſo as to preſerve ſome regularity. Where the head is conſiderably crowded with wood, let the worſt of the redundancy be thinned out as regularly as poſſible, cutting them cloſe to their origin; obſerve likewiſe where any vigorous ſhoots ariſe in the heart of the tree towards the bottom of the old branches, and grow upright and crowd the middle of the head, they ſhould be conſtantly retrenched to their very bottom; cut out alſo any very cankered parts, and all decayed wood, and clear off all ſuckers from the root and ſtem.

Standard trees thus diſburthened from any conſiderable irregularities and confuſion, ſo as all the proper branches have full ſcope to ſpread free and eaſy in their natural manner, they will not fail to repay the trouble in the ſuperior quality of their future fruit.

*Pruning Foreſt Trees, &c.*

With reſpect to Pruning of foreſt and ornamental tres, flowering ſhrubs, &c. it is very inconſiderable.

Foreſt trees, &c. muſt be ſuffered to run up as faſt as poſſible, ſo their heads muſt not be ſhortened; all that is neceſſary is, to prune off lateral branches occaſionally from the ſtem, or if while young, any lateral ſhoot of the head is of a very rude rambling growth, and draws all the nouriſhment, it is proper to reduce it as you ſee convenient: but otherwiſe ſuffer the top and all the branches of the head to remain entire, and take their own natural growth; only prune lower ſtragglers occaſionally; obſerving, however, it is very improper to trim up the ſtem too high, as often practiſed to foreſt trees, as ſcarce to leave any head: never, therefore, trim the ſtem much higher than the full ſpread of the head, for a full head is both ornamental and eſſentially neceſſary to the proſperity of the tree. See PLANTING.

And as to the ſhrub kind, they ſhould alſo, for the general part, take their own growth at top; and only prune occaſionally any lower ſtragglers, from the lower part of the ſtem, or any very irregular rambling ſhoot of the head, and all dead wood: but except in theſe caſes, let their heads moſtly ſhoot in their own way, according to their different modes of growth, in which they will appear always the moſt agreeable.

Where, however, it is required to keep ſhrubs low, in any particular compartment, you muſt regulate this as you ſhall ſee convenient, either with a knife or garden-ſhears, though knife Pruning is the moſt eligible.

*Pruning Implements.*

For the purpoſe of general Pruning, ſeveral implements are neceſſary, ſuch as Pruning-knives, ſaws, chizzels, hand-bills, hatchets, &c.

As to Pruning-knives, two or three different ſizes are requiſite, in order to enable us to prune neatly; a ſtrong one for cutting out larger branches, ſhoots, &c. and a ſmall one for the more exact Pruning among the ſmaller branches and ſhoots of peach and nectarine-trees, &c. theſe knives are generally made curving at the point; they ſhould not be too long, broad, and clumſey, but have rather a ſhortiſh narrow blade, and but very moderately hooked at the point, for when too crooked they are apt to hang in the wood, and not cut clean; it is alſo proper to be furniſhed with a ſtrong thick-backed knife, to uſe by way of a chiſſel occaſionally, in cutting out any hard ſtubborn ſtumps, &c. placing the edge on the wood, and with your nailing hammer ſtrike the back of it, and it will readily cut through even and ſmooth.

Pruning hand-ſaws are proper for cutting out any large branch too thick and ſtubborn

for the knife; they ſhould be of moderate ſizes, one of which ſhould be quite ſmall and narrow, in order to introduce it occaſionally between the forks of the branches, to cut to exactneſs.

As ſaws generally leave the cut rough, it is proper to ſmooth it with a knife or a pruning chiſſel.

Pruning chiſſels are neceſſary to uſe occaſionally, both to cut off any thick hard branch or ſtump, and to ſmooth cuts after a ſaw; they ſhould be flat, and from about one to two inches broad; ſometimes large ſtrong chiſſels, fixed on a long pole, are uſed in Pruning or lopping branches from the ſtems of high ſtandard foreſt trees, one man holding the chiſſel againſt the branch, while another, with a large mallet or beetle, ſtrikes the end of the pole.

A hand-bill and hatchet are alſo neceſſary to uſe occaſionally among larger kinds of the ſtandard trees.

All theſe Pruning tools, in their proper different ſizes, may be had at all the cutlery ſhops and ironmongers, alſo of many of the nurſery and ſeedſmen; and as the expence of the whole will be but trifling, every one ſhould furniſh himſelf properly.

PRUNUS, Plum-tree; compriſing alſo the Cherry-tree, Apricot, &c.

This noted genus comprehends different ſorts of valuable fruit-trees, ſome flowering ſhrubs, and beautiful ever-greens; and to ſome it may ſeem ſtrange to ſee the Cherry-tree, Apricot, Laurel, &c. arranged as ſpecies of the Plum-tree, as being formerly conſidered each as a diſtinct genus; but late diſcoveries in botany prove them to be all ſpecies of *Prunus*, and modern botaniſts range them accordingly; all the ſpecies of which are of hardy growth, garniſhed with ſimple, ſpear-ſhaped and oval leaves, and pentapetalous icoſandrious flowers, ſucceeded by drupaceous fruit.

Claſs and order, *Icoſandria Monogynia*.

*Characters.*] CALIX, is monophyllous, bell-ſhaped, five-parted, and deciduous. COROLLA, five large, roundiſh, ſpreading petals. STAMINA, twenty or more filaments inſerted into the calix, and ſhort didymous antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and orbicular ſtigma. PERICARPIUM, a roundiſh dupraceous fruit, incloſing a roundiſh, compreſſed, hard nut.

The principal ſpecies of this genus are—common cultivated Plum tree, having numerous varieties: Bullace-tree—Sloe-tree, or Black-thorn—Cherry-tree, having many varieties—Padus, or Bird Cherry—Apricot-tree, many varieties—and Laurel-tree:—obſerving, that although all of the ſame genus, ſeveral of the ſorts differ materially from one another, we therefore think it eligible to range or claſs them according to their nature or kinds, under the following heads—Plum kinds—Cherry kinds—Apricot kinds—Laurel kinds, &c. all however under the generical name *Prunus*.

*Plum Kinds.*

Under this head we may compriſe three ſpecies, viz.—1. Cultivated Plum-tree, and its numerous varieties.—2. Bullace-tree.—3. Sloe-tree.

1 PRUNUS *domeſtica*.

*Domeſtic Prunus, or common cultivated Plum-tree.*] Grows twenty or thirty feet high, garniſhed with oval ſpear-ſhaped leaves, and with the pedunculi for the moſt part ſingly, terminated by white flowers, ſucceeded by Plums, of many different ſhapes, ſizes, colours, and properties in the varieties.

*Varieties.*] The varieties of the above ſpecies are very numerous, eſpecially of the fruit; all the different ſorts being varieties of this ſpecies, though the trees of the different varieties often differ ſomewhat in their growth, ſome being ſtrong ſhooters, others moderate, and frequently vary in the ſize and colour of their ſhoots and leaves; thoſe bearing large fruit have generally larger leaves in proportion; and the ſhape, ſize, &c. of the fruit is alſo very conſiderable in different varieties, ſome being round, others oval, and ſome being not much larger than Cherries, others as large as eggs; and ſome are yellow, others red, and ſome green, &c. all of which varieties ripen perfectly in our gardens and orchards.

Principal varieties of the fruit are,

*White Primordium, or Jean Hative Plum.*—A ſmalliſh, oblong, yellow Plum, powdered with a white bloom, eſteemed chiefly for its early perfection; ripe the middle or end of July.

*Morocco, or early black Damaſk Plum.*—A middle-ſized, round, blackiſh fruit, powdered with blue, is well flavoured, and diſcharges the ſtone; ripe end of July.

*Little Damaſk Plum.*——A ſmall, round, black, well-flavoured Plum; ripe end of July or beginning of Auguſt.

*Great*

*Great Damaſk Violet Plum.*—A moderately large, roundiſh-oval, dark-blue Plum, covered with a violet bloom, is of a rich juicy flavour, and quits the ſtone; ripe in Auguſt.

*Queen Claude Plum, ſometimes called Green Gage.*—A middle-ſized, round, yellowiſh-green Plum, having a firm deep-green pulp, of a fine rich flavour, and quits the ſtone; ripe in September.

*Little Queen Claude Plum.*—A ſmall, round, whitiſh-yellow Plum, powdered with white, and parts from the ſtone; ripe end of Auguſt and beginning of September.

*Green Gage Plum.*—A middle-ſized, roundiſh, green Plum, ſometimes purpliſh on the ſunny ſide, having a yellowiſh-green firm pulp, of a moſt delicious rich flavour, but does not diſcharge the ſtone freely; is one of our moſt valuable Plums, and the tree a great bearer; ripe the end of Auguſt and beginning of September.

*Varieties.*] There are ſeveral varieties of greeniſh Plums, that go by the name of Green Gages, that are of inferior quality.

*Blue Gage Plum.*—A middle-ſize, roundiſh, blueiſh Plum, of a rich flavour; ripe beginning or middle of September.

*Orleans Plum.*—A middle-ſized, round, pale-red Plum, often of a whitiſh-green colour on the ſide away from the ſun; is of but a middling flavour, and quits the ſtone clean. The tree is of ſpreading growth, a remarkably great bearer, and very profitable for common uſe, and for thoſe who ſupply the markets; ripe end of Auguſt and beginning of September.

*Drap d'Or, or Cloth of Gold Plum.*—A middle-ſized, roundiſh, bright-yellow Plum, ſpotted with red, of an excellent vinous flavour, and adheres to the ſtone; ripe beginning or middle of September.

*Black Perdrigon Plum.*—A middle ſized, oval, dark-coloured Plum, powdered with a violet bloom; is of a fine rich flavour; ripe middle or end of Auguſt.

*Blue Perdrigon Plum.*—A large, roundiſh, blueiſh-coloured Plum, replete with a delicious juice; ripe end of Auguſt.

*White Perdrigon Plum.*—A middle-ſized, oblong, whitiſh-yellow fruit, covered with a white bloom; is firm, juicy, rich, and quits the ſtone; ripe end of Auguſt and beginning of September.

*Roche Courbon, or Red Diaper Plum.*—A middle-ſize, round, fine-red Plum, powdered with a violet bloom, is high flavoured, and adheres to the ſtone; ripe end of Auguſt.

*Red Imperial Plum.*—A large, oblong-oval, flattiſh, pale-red Plum, covered with a whitiſh bloom; is of but a middling reliſh, and parts from the ſtone; ripe middle of September.

*White Bonum Magnum, Mogul or Egg Plum.*—A remarkably large, oblong, egg-ſhaped, whitiſh yellow Plum, powdered with a white bloom, having a firm pulp that cleaves to the ſtone; more eſteemed for culinary uſe, than eating raw: the tree ſhoots ſtrong, with very large leaves; is a great bearer, and the fruit is the largeſt of the Plum kind; ripe beginning or middle of September.

*Red Bonum Magnum, ſometimes called the Great Imperial Plum.*—A very large, oblong, deep-red Plum; not of a rich flavour, but is excellent for preſerving and culinary purpoſes; ripe beginning or middle of September.

*Fotheringham Plum.*—A large, oblong, fine-red Plum, having a fine rich pulp that quits the ſtone; ripe end of Auguſt and beginning of September.

*Brignole Plum.*—A largiſh, oval, yellowiſh Plum, tinged with red next the ſun, having a firm, dry, rich pulp, is in much eſtimation for ſweetmeats; ripe in September.

*Le Royal Plum.*—A large, roundiſh, light-red, finely-powdered Plum, having a juicy ſugary pulp, that cleaves to the ſtone; ripe end of Auguſt and in September.

*Cheſton Plum.*—A middle-ſized, oval, blackiſh-blue Plum, powdered with a violet bloom; ripe towards the middle of September.

*Wentworth Plum.*—A large, oval, yellowiſh Plum, of an acid reliſh, and ſeparates from the ſtone; is a good culinary fruit; ripe in September.

*Mirabelle Plum.*—A ſmall, round, greeniſh-yellow Plum, having a rich pulp, that diſcharges the ſtone, and the tree a great bearer; ripe end of Auguſt.

*Apricot Plum.*—A large, round, yellowiſh Plum, having a firm, dry, ſweet pulp, that ſeparates from the ſtone; ripe beginning or middle of September.

*St. Catharine Plum.*—A large, oblong, oval, yellowiſh-amber-coloured Plum, powdered with a white bloom, having a rich juicy agreeable pulp, adhering cloſe to the ſtone: ripe end of September.

*Imperatrice Plum.*—A middle-ſized, roundiſh, dark-red, finely-powdered Plum, of an agreeable flavour, the pulp adhering to the ſtone; ripe beginning of October.

*Little Green Damaſk Plum.*—A ſmall, round, greeniſh Plum, powdered with a whitiſh bloom, having a green very agreeable pulp adhering to the ſtone; ripe middle or end of of September.

*Pear Plum.*—A moderate-ſize, oval, whitiſh-yellow Plum, of an inferior flavour, eſteemed principally for preſerving; ripe late in September.

*Muſcel Plum.*—A ſmalliſh, oblong, flat, dark-red Plum, of but an indifferent reliſh; ripe in September.

*Damaſcene Plum.*—A ſmall, roundiſh, dark-blue Plum, of a tolerably agreeable acid reliſh, both for eating and culinary purpoſes, and the tree a great bearer; ripe in September.

*St. Julian Plum.*—A ſmall, round, dark-violet-coloured fruit, covered with a mealy powder, has but little reliſh; ripe end of September.

*Cherry Plum.*—A very ſmall, round, cherry-ſhaped red Plum, valued chiefly as a curioſity; and the tree is often planted among flowering ſhrubs, for the ſake of its beautiful bloom in ſpring, and its cherry-like fruit exhibit a pretty variety in ſummer; though by its flowering very early, the bloom is often cut off, and ſeldom ſucceeded by much fruit.

Thus far is principally all the moſt noted varieties of this fruit cultivated in the Engliſh gardens, and in the nurſeries for ſale; though there are numerous other varieties, particularly of the common ſort, growing in the orchards and hedges of farmers, &c. in different parts of the country; all the ſorts being varieties of one ſpecies, firſt obtained from ſeed, and the approved ſorts of them have been multiplied and continued by budding and grafting. See their *Propagation.*

But beſides the above varieties of the fruit, there are alſo the following for ornamental plantations.

Double bloſſom Plum-tree—Gold ſtriped-leaved—Silver ſtriped-leaved—and the ſtoneleſs Plum.

The two following ſpecies, *Bullace-tree* and *Sloe-buſh*, grow wild in hedges, but are ſometimes cultivated both for variety and uſe.

[2]PRUNUS *Inſititia.*

*Wild Plum, or Bullace-tree.*] Grows twelve or fifteen feet high, the branches ſomewhat ſpinous; oval leaves, hairy underneath, and the pedunculi by pairs, terminated by white flowers, ſucceeded by ſmall, round, Plum-like fruit, of different colours in the varieties.

*Varieties are*] Common black-fruited—White-fruited—Red-fruited; all of which ripen late in autumn. They are very acid, though of a tolerably agreeable flavour, and by many eſteemed very wholeſome, if eaten when quite ripe. They grow wild in the hedges in many parts of England, &c. in great abundance, ſo are not often cultivated: a few plants however merit culture for variety, particularly in the ſhrubbery and wilderneſs compartments, where they will effect an agreeable diverſity in autumn when in fruit.

[3]PRUNUS *Spinoſa.*

*Thorny Prunus, Black-thorn, or Sloe-tree.*] Grows ten or twelve feet high, very branchy and buſhy quite from the bottom, armed with ſtrong ſharp ſpines, ſmall, ſpear-ſhaped, ſmooth leaves, pedunculi growing ſingly, terminated by flowers, ſucceeded by ſmall, round, black berries, in autumn. It grows wild every where in hedges and woods, and is very proper to plant for field hedges, being of very quick cloſe growth. See HEDGES.

The above three ſpecies are all that are proper to arrange under this head, conſidered as of the Plum kind in reſpect to the growth of the trees, and nature of the fruit; though the firſt ſpecies only, and its varieties, are proper for general culture.

The trees of all the ſorts are of the deciduous tribe, of hardy growth, and proſper in any common ſoil and expoſure; they all flower or bloſſom profuſely in the ſpring, April, and beginning of May, and make a fine appearance; all the flowers of every ſort conſiſt each of five ſmall petals, and twenty or more ſtamina, the flowers and fruit being produced on ſhort ſpurs ariſing from the ſides and ends of the branches; and the fruit ripens in autumn, gradually in different ſorts from the beginning of July until October; exhibiting a moſt delightful variety in the different colours, ſhapes, and ſizes, of the cultivated Plum kinds in particular, as well as afford a moſt uſeful ſupply for family uſe, both as excellent table fruit, and for various culinary purpoſes, and for preſerving, &c.

With reſpect to the merit of the different ſpecies, &c. the firſt ſort, *Cultivated Plum-tree* and varieties, every one knows their value as fruit-trees, and no good garden ſhould be without a collection of the beſt ſorts; and as to the ornamental varieties, double bloſſom kind and ſtriped-leaved ſorts, as alſo the Cherry Plum, they are proper for decorating the

ſhrub-

ſhrubbery; but the ſecond and third ſpecies, *Bullace-tree* and *Sloe-buſh*, they are only ſometimes admitted in ſhrubbery compartments, &c. for variety, particularly the former, the fruit of which cauſe an agreeable diverſity whilſt growing, and afford variety at table, when all the more richer ſtone-fruits are gone: as to the Sloe-tree however, its principal merit is to plant for forming field hedges, as before obſerved; it grows thick from the very bottom, and makes a ſtrong cloſe hedge.

The *common Plum-tree* and its varieties may be trained both as dwarfs for walls and eſpaliers, &c. and ſtandards and half ſtandards; thoſe however trained againſt walls and eſpaliers generally produce the largeſt and faireſt fruit, ſo ſhould always train ſome of the beſt ſorts in both theſe ways, and may have any of the varieties as ſtandards in the garden or orchard.

*Propagation of all the above Species and Varieties.*

Firſt, the common Plum-tree.—As to the method of raiſing Plum-trees, all the varieties were firſt obtained by ſeed, *i. e.* from the ſtones of the fruit; and the approved kinds, ſo acquired, were afterwards multiplied by grafting and budding, for they do not continue the ſame ſorts from ſeed, as from the ſeed of one tree there may riſe many different ſorts, and probably not one like the mother-tree, nor very few that produce a fruit worth eating; but being in poſſeſſion of any approved ſorts, they may be multiplied at pleaſure, by ingrafting ſhoots or buds of them into any kind of Plum-ſtocks.

The general propagation therefore of Plum-trees is, by grafting and budding, and may alſo be increaſed occaſionally by layers; but the two former are the moſt eligible methods of propagation.

By Grafting and Budding.—This is performed upon ſtocks of any ſorts of the Plum-kind raiſed from the ſtones, ſowed in autumn in beds of good earth, about two inches deep, and when the plants are a year old, they being planted out in nurſery-rows two feet and a half aſunder, and having from one to two or three years growth, they will be in a fit order to graft or bud with the deſired ſorts, which is performed in the uſual way, either low in the ſtock for dwarfs, and at ſeveral feet height for ſtandards. See GRAFTING and INOCULATION. Obſerving, that when the firſt ſhoots from the graft or bud are one year old, thoſe of the trees deſigned as dwarfs for walls, &c. ſhould be headed down within five or ſix inches of the bottom, more particularly of the budded trees, in order to force out laterals from the lower eyes, ſo as to furniſh a proper ſet of branches, proceeding regularly from the bottom of the tree, to cover every part of the wall and eſpalier. But as to ſtandards, their firſt ſhoots may either be ſuffered to run and branch in their own way, or headed to a few eyes, if it ſhall ſeem neceſſary, to force out lower laterals to give the head a more regular ſpreading formation; afterwards, let them all take their own growth.

When the trees thus raiſed by grafting or budding are from one to two or three years old, they are of a proper ſize for final tranſplanting into the garden, &c. though trees of ſix or eight years old may be ſafely tranſplanted; remarking however, the younger they are planted where they are to remain, the ſooner and more firmly they will eſtabliſh themſelves, and form for bearing.

By Layers.—This is performed on the young wood, any time from November till March, chuſing the laſt ſummer's ſhoots, and lay them by ſlit-laying; in one year they will be rooted, they muſt then be ſeparated, and planted in nurſery-rows, and trained either for dwarfs or ſtandards, as may be required.

The double-bloſſom Plum, the two ſtriped varieties, and ſtoneleſs kind, are all propagated by budding or grafting upon any kinds of Plum-ſtocks, either for dwarfs, or half or full ſtandards.

And the Bullace-tree and Sloe-buſh or Black-thorn, are propagated by ſowing the berries or ſtones an inch deep in a bed of common earth in autumn; and the Sloe-tree alſo abundantly by ſuckers from the root.

Obſerve however, that to continue the different varieties of the Bullace tree diſtinct, they muſt be propagated by budding, grafting, or laying.

*Planting them in the Garden, &c. and general Culture.*

The ſeaſon for planting all the ſorts of Plum-trees is any time in open weather, from the fall of the leaf in November until March.

The trees of all the varieties will ſucceed in any common ſoil of a garden or orchard, and in any open expoſure; allot however ſome of the beſt ſorts for walls and eſpaliers, obſerving thoſe for walls ſhould generally have an eaſt or weſt aſpect, or even a ſouth wall for ſome of the choiceſt ſorts; and ſome may alſo be planted againſt a north wall, to furniſh ſome late fruit: and thoſe for eſpaliers

liers may be planted around any of the open quarters, as may alſo the ſtandards.

Firſt of planting and managing the trees deſigned for walls and eſpaliers.

Plant the wall and eſpalier trees eighteen feet diſtance, though if the walls, &c. are rather low, twenty feet diſtance will be requiſite, in order that in default of a proper height, of walling, there may be more ſcope to train the branches horizontally.

Obſerve, if the trees thus planted are quite young, being only of one year's ſhoot from the grafting or budding, they ſhould in March be headed down, as before obſerved, to four or five eyes, to force out lower horizontals, in the enſuing ſummer, which according as they advance in length, train them in horizontally at full length all ſummer long, unleſs you would forward a farther ſupply of lower branches as faſt as poſſible, when you may pinch the young ſhoots in May down to a few eyes, each will throw out ſeveral laterals the ſame year, which train alſo horizontally at full length during the ſummer's growth; and in winter pruning, cut out only any fore-right and back-ſhoots, and train in all the regular ones at full length, for the branches of theſe trees muſt not be ſhortened only occaſionally to procure wood to fill vacancies, becauſe the branches always form fruit-ſpurs firſt towards their extreme parts, which would be deſtroyed by ſhortening, ſo that after having ſhortened the firſt and ſecond years ſhoots occaſionally, as above, and thereby procured a proper ſet of lower horizontals, to give the head its firſt form; let the whole then be trained in entire about four, five, or ſix inches aſunder, and, according as the trees ſhoot, every ſummer train in a neceſſary ſupply of the regular ſhoots to fill the wall, &c. at the ſame time retrench ſuperfluities and irregular growths, and train the ſupply of regular wood ſtill at full length at the above diſtances; and thus the trees will ſoon cover a large ſpace, and the ſame branches, not ſhortened, will continue bearing many years. See PRUNING.

For all the ſorts of Plums bear principally upon ſpurs, half an inch or an inch long, ariſing from the ſides of the branches, of from one or two to many years old, when trained always at full length; but if ſhortened, they would throw out a multiplicity of uſeleſs wood and hardly any fruit-ſpurs; therefore ſhorten none, except ſome occaſional ſhoots to fill any caſual vacancy, and always train the general branches at full length, both in the ſummer and winter pruning.

Obſerve all the ſorts of wall and eſpalie Plum-trees ſhould be pruned twice every year, a ſummer and a winter pruning, in order to retrench ſuperfluities of each year, and all foreright and other irregular ſhoots, and bad wood, and to train in a neceſſary portion of young wood where wanted to fill vacancies or to ſupply the place of decayed, worn-out, and other bad branches, that may caſually occur, obſerving the general directions for ſummer and winter pruning, under the article PRUNING.

Standard Plum-trees may be trained both as full ſtandards and half-ſtandards, budding or grafting the former ſix feet high, and the latter only three or four; or both kinds may be worked low in the ſtock, and the firſt ſhoot trained to thoſe heights for a ſtem, then let them branch away and form a head.

Theſe ſtandards may be planted both in the garden and orchard, at from about twenty to thirty feet diſtance; which having had their head previouſly ſhortened in the nurſery when one year old from budding, &c. If thought neceſſary, in order to force out lower branches to give the head a ſpreading form, they ſhould now be planted with their heads entire, all but retrenching any irregularity; and ſhould afterwards be permitted to take their natural mode of growth, except juſt reforming occaſionally any croſs placed or very crowded branches, and all dead wood.

*Cherry kinds.*

PRUNUS *Ceraſus*, or Cherry-tree.

The Cherry was formerly placed as a diſtinct genus (*Ceraſus*), but its *characters* proving the ſame as the Plum, and both ſorts readily take by budding or grafting upon one another, it is now retained as a ſpecies of *Prunus*. There is but one ſpecies of the cultivated Cherry, but which, like the Plum, ſports exceedingly in variety; there are however ſeveral ſpecies of the Cherry kind, as Common Cherry-tree—Wild Cherry-tree—Bird Cherry, &c. the firſt of which and its varieties is the principal ſpecies for general culture for the fruit; likewiſe ſome of the Wild Cherry; all the others are for the ſhrubbery and other ornamental plantations.

The ſpecies are,

1 PRUNUS *Ceraſus*.

*Ceraſus, or Common Cherry-tree.*] Grows twenty feet high, or more, garniſhed with oval cluſters of lanceolate, ſmooth leaves, umbellate flowers, ſucceeded by cluſters of roundiſh red fruit of different ſizes and properties in the varieties.

*Varieties.*

*Varieties.*] The above ſpecies comprehends many varieties, the moſt material of which are the following.

*Common Red Kentiſh Cherry.*—The tree forms a ſpreading head, with numerous ſlender branches, bearing round bright-red Cherries, of a ſharp acid reliſh, unleſs permitted to hang till dead ripe, when they become of a dark-red colour, and of a high flavour, is a remarkably great bearer, and proper to cultivate where large quantities are required for ſale, as alſo profitable for private uſe, and if full ripe, is an excellent Cherry; ripe in July.

This variety is ſuppoſed to be the original kind, and that moſt of the other ſorts were firſt raiſed from it.

*Little May Cherry.*—The tree a moderate ſhooter, having ſlender ſhoots and ſmall leaves, and ſmall, round, red fruit, valued chiefly for its early perfection; ripe end of May or beginning of June.

*Common May Duke Cherry.*—The tree large, ſpreading, and a great bearer, having large, round, dark-red, very fine eating Cherries; ripe ſometimes in the end of May, but moſtly in June.

*Arch Duke Cherry.*—The tree large, branching ſtrong and erectly, having larger, round, dark-red fruit; ripe end of June and in July.

*White Heart Cherry.*—The tree is of very large ſpreading growth, producing heart-ſhaped, whitiſh fruit, tinged with a red next the ſun; ripe in June and July.

*Red Heart Cherry.*—A larger, heart-ſhaped, red-coloured, excellent Cherry; ripe June and July.

*Black Heart Cherry.*—A large, heart-ſhaped, very dark-red, rich-flavoured Cherry; ripe end of June and in July.

*Amber Heart Cherry.*—A middling-ſize, heart ſhaped, amber-coloured fruit; ripe middle or end of July.

*Ox Heart Cherry.*—A very large, heart-ſhaped, red Cherry; ripe middle or end of July.

*Bleeding Heart Cherry.*—A large, longiſh, heart-ſhaped, deep-red beautiful Cherry, but the tree no great bearer; ripe middle or end of July.

*Hertfordſhire late Heart Cherry.*—A middle-ſize, heart-ſhaped, firm, good Cherry; ripe end of July and beginning of Auguſt.

*Carnation coloured Cherry.*—A very large, roundiſh, white and red, beautiful, firm Cherry; ripe end of July.

*Lukeward Cherry.* A middle-ſized, roundiſh, dark-coloured, very good Cherry; ripe end of July.

*Morello Cherry.*—The tree a moderate ſhooter, but ſpreading, with numerous ſlender branches, and a great bearer, producing large, round, dark-red fruit, having a tender juicy pulp, of a ſharp acid taſte; but if properly ripened in a ſunny expoſure, is of a rich agreeable reliſh. The trees being generally planted againſt a north wall never ripen the fruit perfectly till late in the ſeaſon, but ſome ſhould alſo be planted on a ſouth wall, to have the full ſun, where the fruit will ripen three weeks ſooner, and attain a much richer flavour, and prove an excellent Cherry for the table; ripe in Auguſt and September.

*Coroun, or Corone Cherry.*——A middle-ſize, round, black, very juicy, excellent Cherry, and the tree a great bearer; ripe end of July and in Auguſt.

*Double-bloſſomed Cherry.*—The tree is of a moderate growth, and produces large, very double, pure-white flowers, of great beauty placed on long ſlender foot ſtalks; each flower being as double as any roſe, riſing in great abundance all over the tree, and make a fine ornamental appearance in the ſhrubbery and other compartments of the pleaſure-ground; flowering in May, but rarely any fruit, except ſometimes from ſome ſemi-double flowers.

*Red-bloſſomed Cherry.*—Having pale-red flowers.

Theſe are all the principal varieties of Cherries proper for general culture, and trees of all the ſorts are ſold at the public nurſeries by the above names, annexed to each variety, all of which are deciduous, and of hardy growth, will ſucceed in any common ſoil and ſituation, and bear well both in dwarfs for walls and eſpaliers, and in ſtandards of all ſorts. See their culture.

²PRUNUS *Avium.*

*Great Wild Cherry-tree.*] Grows forty or fifty feet high, having oval ſpear-ſhaped leaves, downy underneath, and umbellate ſeſſile cluſters of white flowers, ſucceeded by ſmall round fruit of different properties in the varieties.

*Varieties are.*] Common, ſmall, black, wild Cherry—Red wild Cherry—Larger fruited wild Cherry; ripe end of July and in Auguſt.

The trees of all the varieties of this ſpecies grow very large, and grow wild in England, &c. in woods and hedges, but are pro-

per

per to cultivate both as fruit, foreſt, and ornamental trees, and are often planted in gardens, avenues, lawns, and parks, as they make a fine appearance in ſpring when in bloſſom, and bear great crops of fruit, which ſucceed the varieties of the cultivated Cherry, and though ſmall, is of an agreeable flavour; and conſidered as timber-trees they are greatly eſteemed by the cabinet-makers, turners, and ſome other trades, the timber being of a fine reddiſh colour.

The following are the Bird Cherry kinds, cultivated chiefly for ornament, the fruit being not good to eat; but being greatly coveted by the birds, have the appellation of Bird Cherry.

[3]PRUNUS *Padus.*

*Padus, or common Bird Cherry.*] Grows fifteen or twenty feet high, of a ſhrub-like growth, and with a ſpreading head, large, oblong, rough, ſerrated leaves, having two glands at the back of their baſe, and long looſe cluſters of white flowers, ſucceeded by ſmall, round, black fruit in Auguſt.

*Variety.*] *Corniſh cluſter Bird Cherry*, having generally a taller upright ſtem, a more compact regular head, broader leaves, diſtinguiſhed however with two glands at the back of the baſe like the other, and with ſhorter, more compact cluſters of flowers, ſucceeded by larger red fruit.

The common ſort grows wild in hedges in the northern parts of England.

[4]PRUNUS *Virginiana.*

*Virginian Bird Cherry.*] Grows thirty feet high, dividing into a very branchy head, having a dark-purple bark, oval, ſlightly ſerrated, ſhining, green leaves, having two glands at the fore part of the baſe, and long cluſters of white flowers, ſucceeded by ſmall, round, berry-like, black fruit.

[5]PRUNUS *Canadenſis.*

*Canada Dwarf Bird Cherry*] Grows but four or five feet high, branching horizontally near the ground, and have ſmooth branches, broad, ſpear-ſhaped, rough, downy leaves, without glands, and long cluſters of white flowers, ſucceeded by ſmall, round, berry-like, black fruit; ripe in autumn.

[6]PRUNUS *Mahaleb.*

*Mahaleb, or Perfumed Cherry.*] Grows ten or fifteen feet high, having ſmooth whitiſh branches, ſmall, oval, ſhining-green leaves, and corymbous cluſters of white flowers, ſucceeded by ſmall fruit.

All the above five ſpecies of the Cherry kind arranged under this head, flower commonly in April and May, ſo abundantly as in a manner to cover the branches, each flower having five ſmall petals, and twenty or more ſtamina, as obſerved of the Plums, ſucceeded by fruit all of the Cherry kind; ripening in different ſorts from May until September; remarking however, that the fruit of two ſpecies only are eſculent, *i. e. Common Cherry-tree* and its varieties, and the *Great Wild Cherry*; thoſe of the other ſpecies being of a diſagreeable reliſh.

All the varieties however of the common Cherry-tree and great Wild Cherry merit culture for their fruit; and as Cherries in general are valuable as a moſt refreſhing fruit in the heat of ſummer, and for their attaining the earlieſt perfection for eating raw of any of our tree fruits, every good garden ſhould be furniſhed with a collection of the trees of different ſorts, but principally of the common Cherry and varieties.

But the double-bloſſom kind, &c. and all the ſorts of Bird Cherry and the Perfumed Cherry are employed principally in ſhrubberies for ornament and variety.

The common Cherry, in all its varieties, is cultivated both in gardens for walls, eſpaliers, and ſtandards, and in orchards, both in aſſemblage with other ſtandard fruit-trees; and in many places whole orchards of them, in full ſtandards, are planted, in order to ſupply the markets with the fruit. In gardens, however, it is proper to have a portion both as dwarfs for walls and eſpaliers, and half and full ſtandards; and if ſome of the beſt kinds are planted againſt walls of different aſpects, they will furniſh a ſucceſſion of ripe Cherries from May until September, beſides the ſupply from the eſpaliers and ſtandards; for the trees will bear in all expoſures; but it is highly proper to have ſome of the earlieſt and other more valuable kinds againſt a ſouth or ſouth-eaſt wall; thoſe in the ſouth expoſures will ripen ſooneſt, and will be ſucceeded regularly by the others in the eaſt, weſt, and north aſpects; a north wall however is very commonly allotted for Morello Cherries in particular; but as this is a moſt excellent Cherry when well ripened, it is eligible to allow a ſhare of the trees a ſouth aſpect, where they will ripen ſooner and in greater perfection; and thoſe planted againſt a north wall will ſucceed them, and continue until September. However, where there is ſcope of ground and different

different ſituations, it is adviſable to plant ſeveral different ſorts accordingly, whereby a conſtant ſupply of ripe Cherries may be obtained for near three months.

Conſiderable orchards of theſe trees are planted in ſome parts, particularly in Kent, for the ſupply of the London markets, conſiſting principally of the Kentiſh and Duke Cherries, as being the moſt certain beſt bearers; but it is proper to plant ſome of all the varieties.

The Wild Cherry is always trained for ſtandards, and planted in any open ſituation. Great quantities of them are planted in hedge-rows, round fields, in ſome of the counties round London, for the ſake of the fruit to ſupply the markets.

The mode of bearing of all the varieties of theſe trees is, both on the year-old wood, and that of many years, principally upon ſhort ſpurs ariſing from the ſides of the branches, if not ſhortened, but if ſhortened they throw out wood-ſhoots and no fruit-ſpurs, therefore the branches of theſe trees muſt not be ſtopped, but ſuffered always to remain at full length.

All the ſorts of theſe trees will proſper in any common ſoil, capable of producing good crops of eſculent herbs and roots, graſs and corn, &c.

*Method of propagation and general culture.*

The method of propagation for all the varieties of the Common Cherry-tree is by grafting and budding them upon ſtocks of the Wild Black and Red Cherry, raiſed from the ſtones of the fruit: they will, however, grow upon any ſort of Cherry-ſtock; and they will likewiſe take upon Plums, though plum-ſtocks are not adviſed for general uſe; they will alſo grow upon laurel-ſtocks, which, however, is only ſometimes practiſed for curioſity, ſuffering a ſmall part of the ſtock to grow up to ſhew the ſingularity of the two ſorts growing upon the ſame root. All the varieties will likewiſe grow upon the Bird-cherry, but this ſhould only be practiſed when required to dwarf any trees as much as poſſible; which being grafted on the common or Canada Bird-cherry, are proper to plant in pots, for forcing in frames, or to plant in the borders of a forcing-frame. See FORCING FRAME, However, for general uſe, always uſe the Wild Cherry-ſtocks, as being the freeſt ſhooters and of longeſt duration, though in default of theſe, may uſe any ſort of common Cherry-ſtocks.—And as to the method of raiſing them, it is from the ſtones of the fruit, ſowed in autumn in beds of light earth, covering them near two inches deep, they will come up in the ſpring; and in autumn or ſpring following, if the plants are ſtrong, tranſplant them in nurſery-rows two feet and half aſunder, to remain for grafting, &c. which, when about the ſize of a large gooſe-quill or little more, they will be fit to work for dwarf trees; but for ſtandards they muſt have at leaſt four years growth, becauſe they muſt be grafted at ſix feet height.

The grafting and budding all the ſorts is performed in the uſual way, though grafting is moſt to be recommended for general practice, as they are not ſo liable to gum as budded trees; and whip-grafting is the moſt eligible method; obſerving to graft or bud the dwarfs near the ground, and the half and full ſtandards from three to ſix feet high: the grafted trees will ſhoot the ſame year, and the budded ones not till the ſpring following.

Obſerve, that when the firſt ſhoots from the graft or bud is a year old, thoſe of the dwarf trees for walls, &c. muſt be ſhortened down in March or beginning April, to five, ſix, or eight inches long, according to their ſtrength, to procure lateral ſhoots to form the head; but as to the ſtandards, they may be ſhortened or left entire as the caſe requires. If you would have them form a ſpreading head, the firſt ſhoots may alſo be ſhortened to force out lower branches; after this let the branches both of the dwarfs and ſtandards remain moſtly at their full length; and whilſt the trees continue in the nurſery, train thoſe deſigned for walls, &c. to ſtakes, in a proper poſition, and pinch young ſhoots in ſummer to procure more branches which ſtill continue entire.

When the trees are from one or two, to five or ſix years old, they are proper for final tranſplantation into the garden and orchard, though if planted when their heads are not more than two or three years old, they will ſucceed much better than larger trees.

The ſeaſon for planting them may be any time, in open weather, from the end of October, or beginning of November, till March.

Plant the wall and eſpalier trees eighteen or twenty feet diſtance; and if the walls are tolerably high, may plant a half or full ſtan-

dard in the ſpaces between the dwarfs, that whilſt theſe cover the bottom and middle, the ſtandards cover the upper part of the wall.

The management of theſe trees, thus planted againſt walls, and eſpaliers, is principally as follows.—Firſt, obſerve, that if they were planted when only one year old, from the grafting, &c. with the firſt ſhoot from the graft or bud entire, they ſhould be pruned ſhort in March or beginning of April, as obſerved in their nurſery culture, to furniſh lateral branches; but if they were headed in the nurſery, and horizontals thereby obtained, they muſt not be ſhortened now nor hereafter, except occaſionally pinching ſhoots to fill a vacancy, for as the fruit-ſpurs firſt riſe towards the upper ends of the branches, a general ſhortening would not only cut away the firſt fruitful parts, but force out a great deal of uſeleſs wood; let therefore the neceſſary branches ariſing every year after the firſt heading down, be trained horizontally at full length, five or ſix inches aſunder, and if wood is wanted pinch ſome adjacent young ſhoots in May or early in June, or ſhorten it in the ſpring following, and it will puſh forth two or three laterals; being careful to retrench all fore-right and other irregular-placed ſhoots, and continue training the regular branches ſtill at full length, at equal diſtances, till they have filled the allotted ſpace of walling or eſpalier; thus, by arranging the branches entire, they will ſoon ſpread conſiderably, and emit numerous fruit-ſpurs all along their ſides, and in two or three years bear abundance of fruit.

Obſerve the bearing wood does not want renewing annually; but the ſame branches continue bearing ſeveral years, and only wants renewing with young wood occaſionally, as any branch becomes barren or an ill bearer.

They muſt, however, be pruned twice every year; a ſummer pruning early in the ſeaſon, to retrench all evidently ſuperfluous ſhoots ſoon after they are produced, likewiſe all fore-right and other ill-placed ſhoots, and rank wood, as ſoon as poſſible; and to pinch ſhoots where wood is wanted, ſo as there may be as little pruning as poſſible upon the older wood, which is apt to gum by much cutting, retaining however a general moderate ſupply of the regular-placed ſhoots, to chuſe from in the winter pruning, training the whole at full length: and in winter pruning, retrench any caſual worn-out branch or decayed parts, retaining young in their ſtead; and cut out all ſuperfluous or unneceſſary ſhoots, reſerved this ſummer, not now wanted, leaving only ſome well-placed ones in any vacant ſpaces; then nail all the branches regularly to the wall, &c. ſtill at full length. See SUMMER and WINTER PRUNING.

Obſerve in both ſeaſons of Pruning, in cutting out the uſeleſs wood, always to cut every thing quite cloſe. See PRUNING.

Likewiſe be particularly careful to preſerve the fruit-ſpurs, only retrenching ſuch as become very old, unſightly, and barren.

Standard Cherries ſhould be planted twenty-one feet diſtance at leaſt, though, if for a whole orchard, twenty-four feet, or eight yards diſtant every way will be requiſite. Obſerve that the firſt ſhoots having been previouſly ſhortened in the nurſery, if thought neceſſary, to promote lower branches to form the head, plant them now with their heads entire, except juſt reducing any irregular growth, and ſuffer them to branch every way, and ſhoot in length as faſt as they are able, not ſhortening any, and all the branches will ſoon form numerous fruit-ſpurs.

Very little Pruning is required for Standard Cherries, and the leſs the better, as too much uſe of the knife cauſes them to gum and canker; therefore, all that is neceſſary is, occaſionally to retrench any very irregular-growing branch, and all decayed wood.

The Double-bloſſomed Cherry is alſo propagated by grafting or budding, like the other varieties, upon any kind of Cherry-ſtocks, and may be trained both as dwarfs and half and full ſtandards, to effect the greater variety in the plantations.

The Wild Cherry-tree is eaſily raiſed from ſeed, i. e. the ſtones of the fruit; though if any variety produces a larger and finer fruit than common, it may be continued by grafting, &c.—To raiſe them, however, from the ſtones, procure a quantity in autumn, when the fruit is dead ripe, and ſow them in beds of light earth an inch and half deep; they will come up in the ſpring, and after having one or two years growth, plant them out in nurſery-rows, with their tops entire; here train them up for ſtandards, with ſtems ſix feet high, then let them branch out every way to form heads.

They may be planted out as ſtandards in gardens, orchards, or any open grounds for

for the fruit, and in ornamental plantations of foreſt trees.

All the ſorts of *Bird Cherry* are alſo propagated plentifully by the ſeed or ſtones of the fruit; ſowed in the autumn in light earth, near an inch deep; the plants will riſe in the ſpring, and in a year after ſhould be planted out in nurſery-rows two feet aſunder, to remain a few years till fit for the ſhrubbery, &c.

Theſe ſorts may alſo be propagated by layers, which will readily ſtrike root and be fit for tranſplanting in one year. They will alſo grow by cuttings planted in autumn.

The *Perfumed Cherry* is alſo often propagated by grafting upon any ſort of Cherry-ſtocks, raiſed as before directed in the propagation of the common Cherry-tree, and may alſo be tried by layers.

*Apricot kinds.*

PRUNUS *Armeniaca.* Apricot-tree.

Under this head is ranged only one ſpecies, the *Armeniaca* or Apricot, a choice fruit tree, comprehending many valuable varieties of the fruit: it was formerly ranged as a diſtinct genus (*Armeniaca*), but is now a ſpecies of PRUNUS.

Claſs, order, and characters the ſame as the Plum-tree, (*Prunus domeſtica.*)

The ſpecies is,

PRUNUS *Armeniaca.*

*Armeniaca, or Apricot-tree.*] Grows twenty feet high, with a large ſpreading head, having reddiſh ſhoots, large nearly-heart-ſhaped leaves, and cloſe-ſitting pale-red flowers, riſing all along the ſides of the young branches; ſucceeded by large roundiſh fruit, of a yellow and reddiſh colour in different varieties.

The moſt noted varieties of this fruit in the Engliſh gardens are,

*Early White Maſculine Apricot.*—A ſmall round whitiſh yellow fruit, ripe towards the middle of July.

*Early Red Maſculine Apricot.*—A ſmall round fruit, reddiſh next the ſun, and of a juicy agreeable flavour; ripe middle or latter end of July.

*Orange Apricot.*—A large roundiſh fruit of a deep-yellow colour, tinged with red next the ſun, having a firm but rather dry pulp, is however a handſome fruit; ripe beginning or middle of Auguſt.

*Algiers Apricot.*—An oval ſomewhat compreſſed pale-yellow fruit, is tolerably juicy and well flavoured; ripe early part of Auguſt.

*Roman Apricot.*—A large, roundiſh, yellow fruit, firm, juicy, and well flavoured; ripe beginning or middle of Auguſt.

*Turkey Apricot.*—A very large, oval, compreſſed, deep-yellow fruit, having a firm well flavoured pulp; ripe beginning or middle of Auguſt.

*Temple Apricot.*—A middle-ſized, roundiſh, compreſſed, deep-yellow, firm, good fruit; ripe middle of Auguſt.

*Breda Apricot.*—A large, roundiſh, deep-yellow fruit, having an orange-coloured pulp, is an excellent Apricot, and the tree a good bearer both againſt walls and in eſpaliers and ſtandards; ripe middle or end of Auguſt.

*Bruſſels Apricot.*—A moderate-ſized roundiſh-oval fruit, ſpotted with red next the ſun, the other ſide yellow, having a deep orange-coloured, firm, high flavoured pulp; and the tree bears well againſt a wall and in ſtandards; ripe middle and end of Auguſt.

All the varieties of theſe trees bloſſom early in the ſpring, about the end of February and in March, ariſing principally from the ſides of the young ſhoots of the former year, immediately from the eyes or buds; alſo ſometimes upon ſpurs from the two years old wood, and the flowers are ſucceeded by young fruit in April, encreaſing gradually in magnitude till July and Auguſt, when they attain perfection; obſerving they ſhould be gathered before they become quite ripe, otherwiſe they will eat very mealy and with no flavour, but being gathered as ſoon as one ſide becomes a little ſoft, and while the fruit remains entire and firm, they will then eat briſk and agreeably flavoured.

As theſe trees bloſſom and ſet their fruit early in ſpring, often whilſt ſharp froſts and cutting blaſts prevail, frequently deſtroying moſt of the bloom and newly ſet fruit, ſo that they ſometimes have but very thin crops, for which reaſon they require a ſheltered warm ſunny ſituation in this country. In favourable ſeaſons, however, they ſometimes produce five times more fruit than they can nouriſh or bring to due perfection, in which caſe the fruit is always thinned when about the ſize of ordinary cherries, and thoſe thinned off are excellent for tarts.

But the trees of moſt of the ſorts require to be trained againſt a warm wall, in order both to protect their early bloſſom and young

fruit from the injuries of the weather, and to promote the more early and perfect ripening of the Apricots; they will ſucceed in an eaſt or weſt aſpect. It is, however, proper to allow the early, and ſome other kinds, a ſouth wall to effect a variation in the times of ripening.

Some ſorts will alſo bear tolerably in eſpaliers and ſtandards, particularly the Breda and Bruſſels Apricot.

Apricots are valuable ſummer fruit for ſeveral different purpoſes. Green and young for tarts; for which purpoſe, being gathered before the ſtone becomes hard, make the moſt excellent tarts or pies of any fruit ſo early in the ſeaſon. When ripe are very fine table fruit, provided they are gathered before they become ſoft and mealy. And being preſerved in ſugar is an excellent ſweetmeat.

*Method of propagation and general culture.*

Theſe trees are propagated by budding upon any kind of Plum-ſtocks.

The ſtocks for this purpoſe are raiſed from the ſtones of the fruit, ſowed in the autumn in beds of light earth two inches deep; they will come up next ſpring, and in autumn or ſpring following, the plants will be fit to plant out in nurſery-rows, and in a year or two they will be fit to bud for dwarfs for walls, &c. but for half ſtandards and ſtandards they muſt have three, four, or five years growth, and trained up with ſtems from three or four to ſix feet high—though ſometimes the budding for ſtandards is performed low in the ſtock, and the firſt ſhoot trained up for a ſtem.

The budding is performed in Auguſt, being careful to procure ſhoots for the buds from trees of the beſt ſorts, as proved by the fruit they bear; performing the work of budding them in the uſual way. See INOCULATION. The buds will not ſhoot till ſpring, at which time, before they begin to puſh, head down the ſtock a little above the bud, ſoon after which the buds will ſhoot and advance rapidly, and by autumn form a large ſhoot of a yard or more long, and the trees are then proper for planting out for good; obſerving, that whether they remain in the nurſery, or are tranſplanted into the garden, the above firſt ſhoot from the bud muſt, in March following, be headed down to four or five eyes, to procure lower horizontals, as obſerved of the Plums and Cherries.

When, however, the trees are of one year's growth, with their firſt ſhoots or head entire, they are of a very proper ſize for planting out finally where they are to remain. They may be planted any time in open weather from October until the beginning of March, chuſing a ſouth wall for the early, and ſome other kinds to come in forward; but as thoſe expoſed to the full ſouth ſun are apt to become ſoon mealy, it may be proper to plant the principal ſupply againſt eaſt and weſt walls.

They do not require any particular ſoil or compoſt, but will ſucceed in any common ſoil of a garden; previouſly trenching the borders two ſpades deep.

Plant them in a range cloſe along the wall, at eighteen feet diſtance, with their heads entire for the preſent, which faſten either to the wall or to ſtout ſtakes, one to each tree, to preſerve them ſteady until ſpring, when they muſt have their firſt pruning, &c.

Their management, after being planted in the garden, is as follows: in the firſt place obſerving, that if the trees are only one year old, with their firſt head from the bud entire, they muſt be headed down in the ſpring, as aforeſaid, to four or five eyes, to force out branches below; after this give the trees water in dry weather, and they will readily puſh out ſhoots from all the remaining eyes, which in ſummer nail up regularly to the wall at their full length, and if any fore-right or back ſhoots come out, rub them off, being careful to continue the regular ſhoots to the wall all ſummer and the following winter; and in ſpring ſhorten each ſhoot to about eight, ten, or twelve inches, according to their ſtrength, leaving the lowermoſt ones, on each ſide, rather the longeſt; this pruning ſhort being ſtill neceſſary in order to procure a farther ſupply of lower branches, that every part of the wall may be occupied quite from the bottom, having particular attention to preſerve nearly an equal number of branches arranging on each ſide of the tree, and nail them cloſe to the wall in a horizontal poſition, about five or ſix inches aſunder. The ſummer following each horizontal will puſh out three or four, or more, new ſhoots, of which, if any riſe fore-right and behind the branches, rub them off early in the ſeaſon, and nail in all the regular ſide ſhoots, at full length, all ſummer, except it is neceſſary to pinch any particular ſhoot early in the ſummer to fill a vacancy as

ſoon

ſoon as poſſible. In the winter pruning examine if there be any ſuperfluities or irregular growths left in ſummer, cut them out cloſe, and let all the regular-placed neceſſary ſhoots be ſhortened, though they ſhould not now be pruned ſo ſhort as in the two firſt years, only cutting each ſhoot according to its ſtrength, from about eight or ten, to fifteen or eighteen inches long; for we may now ſuppoſe the head of the tree to be tolerably well formed, ſhould therefore prune ſo as to obtain both a farther ſupply of wood, and a crop of fruit; and remarking, that as theſe trees bear principally upon the young wood of a year old, it is eligible to train in a general ſupply of young ſhoots, of each year, in every part; the ſame ſhoots producing, at the ſame time, both a crop of fruit and a ſupply of wood for next year's bearing, ſtill remembering that the annual ſupply of wood muſt always be ſhortened in the winter pruning, for if left entire, they would produce only ſome ſhoots near the top, and leave the bottom naked, ſo as, in a few years, the whole tree would become very thin of bearing wood below, and bear only a little towards the extreme parts of the branches; this therefore determines that, in winter pruning, the ſhoots ſhould always be more or leſs ſhortened according to the ſtrength of the tree, ſituation and ſtrength of the reſpective ſhoots, in order to obtain a neceſſary ſucceſſion of young wood annually in proper ſituations, ſo as to continue every part of the tree from the bottom to the extremity, every way regularly filled therewith for bearing: obſerve, likewiſe, that as theſe trees bear alſo upon ſhort ſpurs, ariſing upon the two years old branches, it is proper to preſerve them wherever they appear, only retrenching ſuch as project conſiderably fore-right; leaving all thoſe of one or two inches long, keeping in mind however that the young ſhoots, of one year's growth, are the principal bearers: thoſe produced one year bear fruit the next, and a general ſupply muſt be every year retained, and not ſhortened in ſummer, which would force out laterals from every eye, and ſpoil the ſhoots for next year's bearing; but in winter pruning a general ſhortening, more or leſs, is neceſſary, and the whole tree then regularly nailed to the wall.

Obſerve, they muſt be pruned twice every year, a ſummer and a winter pruning.

The ſummer pruning conſiſts in reforming the irregularity of the numerous ſhoots annually produced in this ſeaſon, beginning in May or early in June, and rub off cloſe all fore-right and back ſhoots, and all evident ſuperfluities and very rude growths; retaining, however, in every part, a full ſupply of the regular ſide-ſhoots, as ſucceſſion-wood for next year's bearing, training them in at full length, as before directed, to remain till the winter pruning, for it is of importance to leave more than a ſufficiency of the well-placed ſhoots at this ſeaſon, to have plenty in every part to chuſe from in the general winter pruning, See PRUNING.

And the winter pruning comprehends a general reform among all the branches and ſhoots, ſuch as the retrenching all worn-out and old naked branches ill furniſhed with bearing wood, as they from time to time occur, to make room for thoſe furniſhed with proper young ſhoots of the preceding ſummer; at the ſame time ſelecting and retaining, in every part, the beſt of the ſaid ſhoots for next ſummer's bearing, cutting out cloſe all the ſuperfluous or unneceſſary and ill-placed ſhoots, as well as part of the former year's horizontals in every part of the tree, to make due room to train the neceſſary ſupply of young wood at proper diſtances; being careful in retrenching the old wood, occaſionally to prune it down either to a young ſhoot, or to ſome convenient branch it ſupports, and is furniſhed with one or more ſuch ſhoots, ſo as every branch may alſo terminate in a young ſhoot for its leader, cutting off all ſmall ſhoots ariſing from the ſides of the main ones, and let the general ſupply of young wood in every part be now ſhortened, according to their ſtrength, for the reaſons before given. The ſmaller ſhoots cut to about eight or ten inches, the middling ones to twelve or fifteen, and the ſtrong ſhoots to eighteen inches or two feet long, pruning them generally to a wood-bud, in order to obtain a ſhoot at the end for a leader, which will draw nouriſhment to the fruit. Cut out alſo all dead wood and cankered parts, and decayed ſpurs and ſtumps; then, as ſoon as one tree is pruned, let it be directly nailed, which ſhould now be performed with great regularity, training all the branches, &c. horizontally, as ſtrait and cloſe to the wall as poſſible at equal diſtances. See PRUNING.

Obſerve, when any of theſe trees are of a ſtrong vigorous growth, they ſhould be treated according to their nature; in ſuch caſe,

caſe, therefore, it is adviſable to leave the ſhoots thicker, and ſhorten them leſs in proportion, that by dividing the ſap among many, and a greater extent of branches, it checks the luxuriancy which would take place in a ſmaller number.

For the more wood we cut out of a vigorous tree, and the more the ſhoots are ſhortened, the more vigorous will the tree ſhoot, and produce but very little fruit.

But the natural inclination of very vigorous trees ſhould in ſome meaſure be indulged, by training as many branches as can be conveniently laid in, and ſhortening them but moderately, ſome very luxuriant ones hardly at all, which being practiſed two or three years, it will reduce them to a moderate growth and good ſtate of bearing, when they may be treated in the common way.

But as the management of this tree, and the Peach and Nectarine, are nearly the ſame, in reſpect to pruning, &c. as they all bear on the young wood, we refer to that article, where full particulars of pruning and training theſe kind of trees are exhibited, which, for the general part may be applied to the Apricot-tree. See AMYGDALUS *Perſica.*

Standard Apricots are ſometimes planted, and in ſome favourable ſeaſons bear tolerably, particularly the *Breda* and *Bruſſels Apricot*, either in half or full ſtandards; the half ſtandards will be more out of the power of the winds and cold air.

They ſhould be planted in a ſheltered warm ſituation, and their culture is the ſame as other ſtandard fruit trees; they require hardly any pruning, except retrenching decayed wood, or any croſs-placed or worn-out branch, and let all the others take their own natural growth.

*Protecting the bloſſom and young fruit.*—As Apricot-trees againſt walls bloſſom very early, both bloſſom and young fruit are very liable to injury from froſt and cutting blaſts; it is therefore adviſable to afford occaſional protection, in unfavourable ſeaſons, to ſome of the forwardeſt and moſt valuable kinds, either with mats, or twigs of evergreens ſtuck between the branches, beginning the covering as ſoon as the bloſſom begins to expand, and continue it till the fruit are fairly ſet; the mats to be uſed on nights and bad weather, but the evergreens to remain conſtantly till all danger is paſt, obſerving the ſame methods as directed for the peach and nectarines. See AMYGDALUS *Perſica.*

*Thinning the fruit.*—In ſome favourable ſeaſons theſe trees ſet many more fruit than can attain perfection; it is therefore proper to thin them when about the ſize of large cherries or a little bigger, which ſhould be done with great regularity, leaving the largeſt, faireſt, and beſt ſituated, to grow to maturity, as directed in thinning peaches.

Thoſe thinned off make moſt excellent tarts, and ſhould always be ſaved for that purpoſe.

### *Laurel Kinds.*

PRUNUS, *Lauro-ceraſus*, or Laurel-tree.

Under this head are ranged two beautiful evergreen trees for ornamental plantations, viz. Common Laurel, and Portugal Laurel.

The ſpecies are,

[1]PRUNUS *Lauro-ceraſus.*

*Lauro-ceraſus*, or *Cherry-bay*, or the *Common Laurel-tree.*] Grows twenty feet high or more; very branchy almoſt from the bottom, making ſtrong green ſhoots; large oblong, ſtiff, ſhining evergreen leaves, having two glands at the back, and cluſters of ſmall white flowers, ſucceeded by large oblong black berries, flowering in April, and the fruit ripens in September, or beginning of October, but is not good to eat.

*Varieties.*] Gold-ſtriped leaved—Silver-ſtriped leaved.

This ſpecies and varieties are ſome of the moſt beautiful evergreens in nature; are of a fine free growth; the leaves ſingularly large and elegant, remaining all the year.

It is a native of the Eaſt, about the Black Sea; but is very hardy, and thrives here in any ſituation.

[2]PRUNUS *Luſitanica.*

*Portugal Laurel.*] Grows twelve or fifteen feet high, forming a very branchy full head, having the young branches of a reddiſh colour; oblong-oval, thick, dark-green, glandulous evergreen leaves, and looſe bunches of ſmall white flowers, ſucceeded by roundiſh black berries; flowering in June, and the fruit ripens in autumn.

Both theſe ſpecies are noble evergreens; are commonly conſidered as ſhrubs, but are of the tree kind; the Common Laurel in particular, becomes a large tree in its native ſoil, and the ſouthern parts of Europe, where there are whole woods of it; both the ſpecies, however, thrive here, which, in many places are arrived to ſome conſiderable ſize, and are great ornaments to our ſhrub-

beries

berries and other plantations, appearing elegantly green and beautiful the year round.

They are hardy, and rarely injured by inclement weather, except in very ſevere winters, which ſometimes kills the young ſhoots and outer leaves.

They proſper in any common ſoil, and in any expoſure; the Common Laurel in in particular will grow almoſt any where, even under ſhady trees, or againſt fences.

Both the ſpecies are moſt excellent furniture for all ornamental plantations, in aſſemblage with the evergreen tribe in particular; and ſome diſpoſed towards the fronts of deciduous plantations have alſo a moſt beautiful effect. Clumps and plantations of the Common Laurel in lawns, parks, or any out grounds, are alſo very beautiful; and as it proſpers in almoſt any ſituation, and being a faſt grower, may be employed to conceal any diſagreeable fence or other unſightly object; in all of which ways they will appear moſt beautiful, at all ſeaſons, with their noble large evergreen foliage.

Hedges are alſo ſometimes formed of this tree for ornament; but where this is practiſed the hedge ſhould not be trimmed with garden-ſhears, which would mangle and ſpoil the beauty of their large leaves; therefore all neceſſary cutting ſhould be performed with a knife, in order to preſerve the leaves entire, and thus the hedge will make a very fine appearance.

It has been hinted by ſome that the leaves and fruit of theſe trees are of a noxious quality, but ſo far from being poiſonous, the the leaves of the Common Laurel are often uſed in the kitchen to put into cuſtards, &c. which gives them a moſt agreeable bitteriſh flavour; and the berries are often put into brandy.

The ſeaſon for planting theſe trees, may be any time in open weather, from October till March or beginning of April, though October and November is the moſt ſucceſsful ſeaſon.

### *Method of Propagation.*

The propagation of theſe beautiful trees is very eaſy, by ſeed and cuttings; but as cuttings is the moſt expeditious mode of propagation, they are moſt commonly raiſed by that method.

By Seed.—In autumn, when the ſeeds or berries are ripe, ſow them in beds of light earth, near an inch deep, and allow them ſome protection in ſevere froſts in winter, either by hooping and matting the bed, or covering it with any dry long litter, but let them remain uncovered all mild weather; with this care the plants will come up in the ſpring, giving occaſional waterings in dry weather, and in the autumn or ſpring following, when the ſeaſon is ſettled, plant them out in nurſery-rows to remain two or three years, or till wanted for any plantation.

By Cuttings.—This is a ſure and very expeditious method of raiſing theſe evergreens; the young ſhoots ſtrike freely, and ſoon commence proper plants. In Auguſt or September, in moiſt weather, procure a quantity of cuttings of the ſame year's ſhoots, cutting them off from about ten or twelve to eighteen inches long, with about an inch of the old wood to the bottom of each cutting if poſſible, though this is not abſolutely neceſſary: having procured the cuttings, ſtrip off the leaves from the lower part, and then plant them in a ſhady border in rows ſix inches aſunder, planting each cutting two thirds into the ground: give water in dry weather, and probably thoſe planted in Auguſt will be rooted the ſame year; they, however, will be all well rooted next ſummer and ſhoot at top, perhaps a foot long by the following autumn, at which time, or in the ſpring after, they may be tranſplanted in wide nurſery-rows, to acquire ſtrength for final tranſplantation.

In both the above methods of propagating theſe trees, they may be trained either buſhy, of a ſhrub-like growth, or trimmed up to a ſingle ſtem for ſtandards.

PSIDIUM, Guava-tree.

Two exotic trees of the Indies compoſe this genus, retained here in ſtoves for variety, garniſhed with oval and oblong leaves, and pentapetalous flowers.

Claſs and order, *Icoſandria Monogynia.*

*Characters.*] CALIX, is monophyllous, campanulate, and five-parted at top.—COROLLA, five oval, concave, patent petals.—STAMINA, twenty or more ſhort filaments, and ſmall antheræ.—PISTILLUM, a roundiſh germen under the calix, long ſtyle and ſimple ſtigma.—PERICARPIUM, a large oval baccaceous fruit, having numerous ſmall ſeeds.

The ſpecies are,

'PSIDIUM *Pyreferum.*

*Pear-fruited Pſidium*] Riſes with a woody thick trunk, branching twenty feet high, having

having quadrangular branches and a ſmooth bark, narrow, oval, obtuſe, oppoſite leaves, and the pedunculi having one flower, ſucceeded by an oblong pear-ſhaped fruit.

[2]PSIDIUM *Pomeferum.*

*Apple-fruited Pſidium.*] Grows twenty feet high; narrow, oblong, pointed leaves, and the pedunculi terminated by three flowers, ſucceeded by apple-ſhaped fruit.

Theſe plants muſt be kept in pots, and always placed in the ſtove.

They are propagated by ſeed obtained from the Weſt Indies; ſowed in pots and plunged in a bark-bed, and when the plants are come up three or four inches high, plant them in ſeparate pots, and treated as other exotics of the ſtove.

PSORALEA.

This genus furniſhes ſome ſhrubby exotics for the green-houſe collection, garniſhed with pinnated and trifoliate leaves, and papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous and five-parted, having the lower ſegments twice the length of the others.—COROLLA, is papilionaceous and pentapetalous.—STAMINA, ten diadelphous filaments and roundiſh antheræ.—PISTILLUM, a linear germen, ſubulate, long, aſcending ſtyle, and obtuſe ſtigma.—PERICARPIUM, a compreſſed pod, having one kiney-ſhaped ſeed.

The moſt noted ſpecies are.

[1]PSORALEA *Pinnata.*

*Pinnated Pſoralea.*] Riſes with a woody ſoft ſtem, branching five or ſix feet high, pinnated leaves of three or four pair of narrow lobes, terminated by an odd one, and at the axillas cloſe-ſitting blue flowers with white keels. It is a native of Ethiopia.

[2]PSORALEA *Bituminoſa.*

*Bituminous trifoliate Pſoralea.*] Riſes with a ſhrubby ſtalk, branching ſparingly, about two or three feet high, ternate or three-lobed leaves of a bituminous ſcent; and blue flowers in cloſe heads.—Grows in Italy and in France.

[3]PSORALEA *Aculeata.*

*Aculeated or Prickly Pſoralea.*] Riſes with a ſhrubby branching ſtem three or four feet high, ternate leaves, having wedge-ſhaped lobes, terminating in a recurved ſharp point, and the branches terminated by roundiſh heads of blue flowers. Grows in Ethiopia.

Theſe plants flower here every ſummer; the firſt ſort greateſt part of that ſeaſon, and the others in July and Auguſt; all of which are ſucceeded by ſeeds in autumn.

Keep them in pots in order for removing into the green-houſe in winter.

They are propagated by ſeeds, ſowed in a hot-bed in the ſpring, and when the plants are two or three inches high, prick them in ſeparate ſmall pots, and gradually hardened to the open air, ſo as to bear it fully by the end of May or beginning of June.

They may alſo be propagated by cuttings any time in ſummer, planted in pots and plunged in a little heat, or covered cloſe with hand-glaſſes, ſhaded from the ſun and watered.

PTELEA, Shrub Trefoil.

The plants are of the ſhrub kind, conſiſting of two ſpecies only, one for the ſhrubbery the other for the ſtove, garniſhed with trifoliate and ſimple leaves, and tetrapetalous flowers in bunches.

Claſs and order, *Tetrandia Monogynia.*

*Characters.*] CALIX, is ſmall and cut into four parts.—COROLLA, four oval-lanceolate ſpreading petals.—STAMINA, four awl-ſhaped filaments, having roundiſh antheræ.—PISTILLUM, a roundiſh compreſſed germen, ſhort ſtyle, crowned by two obtuſe ſtigmas.—PERICARPIUM, a roundiſh bilocular membrane, having two ſeeds.

The ſpecies are,

[1]PTELEA *Trifoliata.*

*Trifoliate Ptelea,* or *Carolina Shrub Trefoil.*] Hath a ſhrubby upright ſtem, dividing into a branchy head eight or ten feet high, covered with a ſmooth purpliſh bark, trifoliate leaves formed of oval ſpear-ſhaped folioles, and the branches terminated by large bunches of greeniſh-white flowers, ſucceeded by roundiſh, bordered capſules.

[2]PTELEA *Viſcoſa.*

*Viſcous Indian Ptelea.*] Riſes with ſeveral ſtrong ſhrubby ſtems, branching erectly twelve or fifteen feet high, having a light brown bark; ſpear-ſhaped, ſtiff, ſimple leaves; and the branches terminated by cluſters of greeniſh flowers

The firſt ſpecies is a hardy deciduous ſhrub, and a proper plant for the ſhrubbery and other ornamental plantations to encreaſe the variety.

The ſecond ſort being of the temperature of ſtove exotics, muſt be kept moſtly in the hot-houſe, except about two or three months in the heat of ſummer, when they may be ſet in the open air.

The

The firſt ſort is propagated by ſeed, layers, and cuttings.

By Seed.—In March, or beginning of April, ſow the ſeed in a bed of light mould, half an inch deep; or to bring them as forward as poſſible, may ſow them in pots, and plunge them in a moderate hot-bed, juſt to bring up the plants an inch or two high: give occaſional waterings all ſummer, and protection from ſevere froſt in winter; and in ſpring following plant them out in nurſery-rows to acquire ſtrength for final tranſplantation.

By Layers.—Perform this in autumn; chuſe the young ſhoots, give them a ſmall ſlit underneath, then lay them in the earth, and they will be rooted in a year's time.

By Cuttings.—In the ſpring cut off a quantity of young ſhoots, plant them thick in pots, which plunge in any hot-bed, or in a bark-bed, juſt to ſtrike them; they will readily root, and be fit to tranſplant the following autumn.

The ſecond ſpecies is propagated commonly by ſeeds: ſow them in pots, and plunge them in a hot bed; when the plants are two or three inches high prick them in ſeparate pots, plunging them alſo in the hot-bed, or in the bark-bed of the ſtove.

PULMONARIA, Lung-wort.

The plants are hardy, herbaceous, fibrous-rooted perennials, medical and flowery plants, riſing with annual ſtalks, from about ten or twelve inches to a foot and half long, having oval and heart and ſpear-ſhaped leaves, and terminated by bunches of pentapetalous flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is monophyllous, five-corned, quinquedented, and permanent.—COROLLA, is monopetalous funnel-ſhaped, with a cylindric tube, and the limb half cut into five obtuſe, erect, patent ſegments.—STAMINA, five ſhort filaments, having erect connivent antheræ.—PISTILLUM, four germens, one filiforme ſtyle, and obtuſe ſtigma.—PERICARPIUM, none; four roundiſh ſeeds lodged in the perſiſtent calix.

There are about ſix ſpecies, ſome are cultivated for medicine, others to encreaſe the variety of the herbaceous collection.

The moſt material ſpecies, are,

[1]PULMONARIA *Officinalis.*

*Common Officinal Spotted Lung-wort.*] Hath the root crowned with oval, heart-ſhaped, rough, white-ſpotted leaves, and upright ſtalks near a foot high, terminated by bunches of red, purple, and blue, flowers.

It is cultivated both for medicine and for variety in the garden:—is good for diſorders of the lungs, coughs, and conſumptions.

[2]PULMONARIA *Anguſtifolia.*

*Narrow-leaved Lung-wort.*] Hath narrow, ſpear-ſhaped, hairy, radical leaves; upright ſtalks about a foot high, terminated by bunches of flowers, becoming of a fine blue colour.

[3]PULMONARIA *Virginica.*

*Virginian Lung-wort.*] Riſes with upright ſtalks about a foot and half high; ſpear-ſhaped, obtuſe, ſmooth leaves; and the ſtalks terminated by cluſters of blue flowers.

*Varieties.*] With red flowers,—purple-flowered—white-flowered.

All theſe ſpecies flower in April and May, and the ſeeds ripen in June and July.

They are all perennial in root, which is of the fibrous kind; but they are annual in ſtalk, riſing in the ſpring, and after having flowered and perfected ſeed they decay: they are very hardy plants and will grow almoſt any where, but delight moſt in ſomewhat ſhady ſituations.

They are propagated by ſeeds and by parting the roots.

By ſeeds.—Sow them in the ſpring in any bed or border of common earth, and rake them in, they will ſoon come up, and in July or Auguſt put out the plants either where they are to remain or in nurſery beds till October, then tranſplanted finally.

By parting the roots.—Autumn, about Auguſt or September, is the proper time; but the ſooner after they have done flowering the better; do not divide them too ſmall, and plant the ſlips directly, and they will flower ſtrong the following ſpring.

PUNICA, Pomegranate tree.

Two ſpecies, of the tree and ſhrub kind, form this genus, one a hardy fruit tree, the other a ſomewhat tender ſhrub, both of them cultivated chiefly for variety; are adorned with ſpear-ſhaped and linear leaves, and pentapetalous fine red flowers.

Claſs and order, *Icoſandria Monogynia.*

*Characters.*] CALIX, is monophyllous, bell-ſhaped, quenquedented at top, coloured, and permanent.—COROLLA, five roundiſh erect ſpreading petals, inſerted into the calix.—STAMINA, twenty or more ſhort filaments having oblong antheræ.—PISTILLUM, a germen under the receptacle, ſingle ſtyle,

and a capitated ſtigma.—PERICARPIUM, a large, roundiſh, apple-ſhaped fruit, having nine cells filled with roundiſh ſucculent ſeeds.

One of the ſpecies *Common Pomegranate-tree*, produces a very large eatable fruit called a Pomegranate, though they ſeldom attain true perfection in this country.

The ſpecies are,

¹PUNICA *Granatum.*

*Granatum, or Common Pomegranate-tree.*] Riſes with a tree ſtem, branching numerouſly all the way from the bottom, growing eighteen or twenty feet high; ſpear-ſhaped, narrow oppoſite leaves; and the branches terminated by large moſt beautiful red flowers, ſucceeded by large roundiſh fruit, as big as an orange, having a hard rind filled with ſoft pulp and numerous ſeeds.

*Varieties.*] Large double-flowered, remarkably beautiful,—ſtriped-flowered.

Theſe trees are deciduous, grow naturally in Italy, Spain, and Portugal, where they ripen fruit abundantly; in this country, however, they require a warm ſituation, and if trained againſt a ſouth wall they will ſometimes produce full-ſized fruit, though it rarely ripens with any tolerable flavour; but as both the flowers and fruit make a fine appearance, a few of the trees merit culture in every good garden.

They all flower abundantly, in July, Auguſt, and September, and the fruit ripens in autumn.

²PUNICA *Nana.*

*Dwarf American Pomegranate* ] Riſes with a ſhrubby ſtem, branching four or five feet high, narrow ſhort leaves, and ſmall red flowers, ſucceeded by ſmall fruit; begins flowering in July and continues till October.

The firſt of theſe ſpecies is a hardy tree, and may be planted for ornament in ſhrubberies and other plantations for the beauty of their flowers; but it is adviſable to plant ſome alſo againſt a warm wall and train them like other wall-trees, they will generally flower more abundantly, and have a chance to ripen fruit; it ſhould be obſerved as they produce their flowers always on the young ſhoots of the year, ariſing principally from thoſe of the year before, that it is therefore proper to train in plenty of the ſtrongeſt beſt placed ſhoots of each year, which in winter ſhould be ſhortened to promote their furniſhing a greater ſupply of young wood in ſummer for flowering; and let them be trained to the wall at equal diſtances, and managed nearly as directed for peaches and nectarines, &c.

The double-flowered variety produces much larger and more beautiful flowers than the others, it is therefore in greateſt eſtimation to cultivate for ornament.

The ſecond ſort being rather tender it is proper to plant it moſtly in pots, in order to have ſhelter of a green-houſe in winter.

Both the ſpecies and varieties are propagated abundantly by layers; autumn is the proper ſeaſon, chuſing the young branches: give a little ſlit at a bud or eye and lay them in the uſual way, giving occaſional waterings in ſummer, and by next autumn they will be well rooted and fit to tranſplant in nurſery rows for two or three years, to get ſtrength, and then planted where they are to remain.

Thoſe of the common ſort and varieties may be trained as ſtandards, either as half or full ſtandards, or as dwarfs.

But thoſe deſigned for walls muſt be managed accordingly, as directed for peaches, &c. as aforeſaid.

PYRUS Pear-tree, comprehending alſo the Apple-tree and Quince-tree.

The Pear, Apple, and Quince, were long conſidered as ſo many diſtinct *genera*, but the botaniſts having diſcovered their *characters* to be alike, have ranged them all as ſpecies of the ſame *genus*; and as ſuch we will alſo conſider them and arrange them accordingly: they are all of the tree kind, adorned with oblong and oval leaves and pentapetalous icoſandrous flowers.

Claſs and order, *Icoſandria Pentagynia.*

*Characters.*] CALIX, is monophyllous, concave, divided into five ſpreading ſegments and permanent.—COROLLA, five large concave petals, inſerted into the calix.—STAMINA, twenty, or more, ſhort awl ſhaped filaments, having ſimple antheræ —PISTILLUM, a germen ſituated under the calix, ſupporting five ſtyles, having ſimple ſtigmas. ——PERICARPIUM, a roundiſh umbilicated fruit with five membranaceous cells, each having one oblong ſmooth ſeed or kernel.

Agreeable to the above *characters* the *Malus*, Apple-tree, and *Cydonia*, the Quince-tree, formerly conſidered as diſtinct *genera*, are by Linnæus retained as ſpecies only of *Pyrus*: they are certainly all of the ſame family, for beſides their agreement in *characters*, all the three ſorts will readily take by graſting and budding upon one another; however, as the

the Pear, Apple, and Quince, have always been conſidered as different ſorts of fruit, each ſort being of a peculiar ſhape and property, and each comprehending many varieties, we will arrange each ſpecies and its varieties under a ſeparate head, viz. Pear Kinds, ——Apple Kinds,——and Quince Kinds, all under the generic name *Pyrus*.

### *Pear Kinds.*

1 *Pyrus Communis.*

*Common Pear tree.*] Riſes with an upright large trunk branching thirty or forty feet high, in ſome widely around, others more erectly, often forming a conical head; oval, lanceolate, ſerrated leaves, and corymbous cluſters of white flowers from the ſides of the branches, ſucceeded by large fruit extended at the baſe; of different properties in the numerous varieties.

The botanic deſcription is——Pyrus with ſerrated leaves and flowers in a corymbus.

*Varieties.*] There is only one ſpecies of this tree, but it comprehends almoſt endleſs varieties, all of which bearing the above deſcription, and all bear their flowers and fruit upon ſpurs, ariſing from the ſides of the branches, of from two or three to many years old, the ſame branches and ſpurs continuing fruitful a great number of years; the different varieties furniſhing fruit for uſe from the beginning of July until May or June next year, which, according to their times of ripening may be divided into three claſſes; Summer Pears, Autumn Pears, and Winter Pears; the Summer Pears ripening in different ſorts from the beginning of July until the middle or end of September, and are generally fit to eat from the tree, or at leaſt, do not keep above a week or two before they rot. And the Autumn Pears attain perfection in October, November, and December; ſome of which ripen nearly on the tree in October and beginning of November, others require to lie ſome time in the fruitery, and ſome will keep two months: but all the Winter Pears, although they attain to their full growth on the tree by the end of October and in November, yet they do not acquire perfection for eating till from the end of November till April and May; thoſe of each claſs having different properties, ſome being melting, others breaking, ſome mealy, and ſome are hard and auſtere and can be uſed only for kitchen uſes; but our liſt conſiſts moſtly of eating Pears, with a few of the choiceſt hard Pears for baking; though any of the large eating Peers may alſo be uſed occaſionally for culinary purpoſes, before they are quite ripe.

As many of the fine ſorts were firſt obtained from France they are ſtill continued in moſt catalogues by the French names; obſerving that the varieties of the fruit are very numerous, we ſhall only give a liſt of the moſt valuable, arranged in three claſſes.—— Summer Pears.—Autumn Pears,—Winter Pears.

### *Summer Pears.*

Summer Pears are ſuch as ripen from the beginning or middle of July until the middle or latter end of September, and continue but a ſhort time in perfection: ſome of the earlieſt ſorts keep good only a few days before they become mealy and rotten; and very few of the ſorts will laſt much above a fortnight; but by having different varieties the ſucceſſion may be continued two months or ten weeks till ſucceeded by the autumnal ſorts, which will continue in eating from the end of September till Chriſtmas.

*Little Muſk Pear.*] A ſmall roundiſh yellow Pear of a muſky flavour, valuable for its early perfection: ripe beginning or middle of July.

*Green Chiſſel Pear.*] A ſmalliſh nearly oblong, light-green, Pear, melting very juicy and agreeably flavoured: ripe middle or end of July.

*Red Muſcadelle, or Faireſt Supreme.*] A middle-ſized, beautiful, red-ſtriped and yellow Pear, ſomewhat firm, breaking juicy and rich flavoured; ripe the end of July and beginning of Auguſt.

*Jargonelle Pear, commonly ſo called, but is properly Cuiſſe Madam, or Lady's thigh.*] A largiſh, long, pyramidal, ruſſety green Pear, tinged with brown next the ſun, having a fine, breaking, juicy pulp, of a moſt delicious rich flavour; is the beſt ſummer Pear in the world, and the tree a good bearer, both in ſtandards, eſpaliers, and againſt walls: ripe beginning or middle of Auguſt.

*Cuiſſe Madam Pear, commonly ſo called, but is properly the Jargonelle.*] A fine large oblong, ſmooth, yellowiſh green Pear, ſometimes reddened next the ſun, having a firm pulp tolerably juicy and agreeably reliſhed, though not high flavoured, and is apt to become mealy when full ripe; but being a large handſome fruit, and the tree a remarkable

good bearer; it highly merits culture, particularly for the ſupply of markets; and for which purpoſe it is greatly cultivated about London: ripe towards the middle of Auguſt.

*Windſor Pear.*] A large oblongiſh Pear, ſwelling conſiderably towards the crown, of a greeniſh-yellow colour, having a ſoftiſh pulp, but ſoon becomes mealy: ripe middle or end of Auguſt.

This ſort and the former bear a great reſemblance to each other, but this is rather ſhorter and more ſwelling towards the crown.

*Great Blanquette Pear.*] A large roundiſh, yellowiſh-green, ſmooth Pear, having a ſoft juicy fleſh of a rich flavour: ripe beginning or middle of Auguſt.

*Little Blanquette Pear.*] A ſmall, roundiſh, ſmooth, yellowiſh-green Pear: ripe middle or end of Auguſt.

*Early Ruſſelet Pear.*] A middle-ſized, oblong, reddiſh Pear, melting and replete with ſugary juice: ripe about the middle of Auguſt.

*Muſk Robine, or Queen's Pear.*] A ſmall, roundiſh, top-ſhaped, yellowiſh-coloured Pear, tender, ſweet, and muſky: ripe middle or end of Auguſt.

*Red Orange Pear.*] A middle-ſized globular Pear, reddened on the ſunny ſide, the other green, melting and richly flavoured: ripe end of Auguſt.

*Perfumed Pear.*] A middling, roundiſh, deep-red Pear, ſpotted with brown, having a melting perfumed fleſh: ripe end of Auguſt.

*Orange Muſk Pear.*] A large, round, yellow Pear, very good if eaten from the tree, as ſoon as a little ripe: it ripens in the end of Auguſt.

*Auguſt Muſcat, or Royal Pear.*] A largiſh, globular, whitiſh-yellow Pear, breaking ſugary and perfumed, and one of the fineſt Pears of the ſeaſon: ripe end of Auguſt.

*Onion Pear.*] A middle-ſized, globular, brown-ſkinned, Pear: ripe end of Auguſt.

*Salviati Pear.*] A largiſh, globular, flatted Pear, reddiſh and yellow to the ſun, and whitiſh on the other ſide, tender and agreeably flavoured: ripe beginning of September.

*Red Admirable Pear.*] A large globular Pear, crimſon-coloured on the ſunny-ſide: ripe in September.

*Summer Bon Chretien, or Good Chriſtian.*] A fine, large, oblong Pear, beautifully reddened next the ſun, and whitiſh on the other ſide, breaking and highly flavoured: ripe beginning of September.

*Roſe Water Pear.*] A middle-ſized, globular, browniſh-red, rough Pear, breaking and finely flavoured: ripe middle of September.

*Summer Bergamot Pear.*] A largiſh, round-flatted, greeniſh-yellow Pear, melting and ſugary: ripe middle of September.

*Varieties.*] There are two or three varieties of this ſort that differ in ſize, but are all of the Bergamot ſhape.

*Orange Bergamot Pear.*] A largiſh, round-flatted, yellow Pear, reddiſh next the ſun, breaking and replete with perfumed juice: ripe towards the end of September.

Other Summer Pears of leſs note are known by the following names;—Catharine Pear,—St. James's Pear,—Crawford Pear,—Citron Pear,—Pear Piper,—Brute Pear,—Muſk-drone Pear—Lemon Pear,—Green Muſk Pear,——Long-ſtalked Blanquette Pear.

All the kinds of Summer Pears ripen on the trees fit for eating, but ſhould be gathered before they are too ripe.

### *Autumnal Pears.*

Autumn Pears are ſuch that attain their full growth on the trees from about the middle or end of September till the end of October; and which after being gathered gradually mellow and improve in flavour, and will keep ſome a month, others ſix weeks, and ſome two months or longer; being in eating principally in October, November, and December.

*Autumn Bergamot Pear.*] A middle-ſized, roundiſh, flatted, yellowiſh green Pear, faintly reddening next the ſun, melting and of a richly perfumed flavour: ripe end of September or beginning of October, continuing good until the end of November.

*Swiſs Bergamot Pear.*] A middle-ſized, roundiſh, greeniſh Pear, finely ſtriped with red, melting and tolerably well flavoured: ripe end of September continuing in eating till November.

*Great Ruſſelet Pear.*] A large oblong brown and reddiſh Pear, ſometimes ſpotted, having a tender rich pulp: ripe middle or end of September.

*Brown Beurre, or Beurre de Roy Pear.*] A fine, large, oblong, ruſſetty, brown and greeniſh Pear, very melting, juicy and ſugary, and is one of the fineſt Pears of the autumn: ripe beginning of October and keeps good till December.

*White*

*White Beurre Pear.*] A large, roundiſh, top-ſhaped, whitiſh-yellow Pear, melting, very juicy and good: ripe beginning of October and keeps till November.

*Red Beurre Pear.*] A large, oblong, reddiſh Pear, melting and very fine: ripe beginning of October.

*Green Sugar Pear.*] A middle-ſized, top-ſhaped, ſmooth, green Pear, full of a rich ſugary juice: ripe end of October, and keeps good all November.

*Monſieur John Pear.*] A largiſh, nearly round, ſwelling, brown Pear, with a rough ſkin, having a breaking delicious pulp: ripe end of October, continuing in perfection all November and part of December.

*Creſane Pear.*] A large, ſomewhat globular, flatted, greeniſh-yellow, ruſſety Pear, hollowed at the top, is remarkably tender and ſweet, and may be ranked as the fineſt Pear of the ſeaſon: ripe end of October, keeping good till December.

*Swann's-egg Pear.*] A moderately large, egg-ſhaped, duſky-green Pear, browniſh next the ſun, is very juicy and agreeably flavoured: ripe end of October, continuing in tolerable perfection till near Chriſtmas.

*Verte Longue, Long Green Pear, or Autumn Mouth-water.*] A large, long, very green Pear, is melting and juicy: ripe in October, and continues till December.

*Marquis's Pear.*] A fine large, ſwelling, flat-topped, greeniſh-yellow Pear, faintly ſpotted with red, having a tender good pulp; is in eating in November and December.

*Grey Good-wife Pear.*] A middle-ſized, roundiſh, browniſh-red Pear, moderately tender and well flavoured; is in eating from the end of October till December.

*Rouſſeline Pear, or Long-ſtalked, late Autumnal Muſcat.*] A large, oblong, long-ſtalked Pear, reddiſh on the ſunny ſide, is tender and of a muſky flavour: in eating in the end of October and part of November.

*Muſcat Fleury Pear.*] A ſmalliſh globular, browniſh-red, long-ſtalked Pear, tender and high flavoured: in eating from October till December.

*Twice flowering Pear-tree.*] It often produces bloſſom twice a year, the firſt in the ſpring, and the ſecond in autumn, ſo is preſerved in many gardens as a curioſity.

Other leſs material autumnal Pears are—Beſideri Pear.—Dean's Pear.—Vicar's Pear.—Vine Pear.—Autumn Roſe Pear.—French Bergamot.—Beurre Bergamot.—Knave's Pear.—Burnt Cat Pear.—Pound Pear, very large.

All the autumn Pears ſhould have their full growth on the tree, but not hang till quite ripe, which is the end of September and in October, being their ſeaſon of full growth.

### *Winter Pears.*

Winter Pears arrive to full growth about the end of October and in November, but do not attain maturity for eating until they have lain ſome conſiderable time in the houſe, ſome a month or ſix weeks, others two or three months or more, before they ripen, as obſerved below in their deſcriptions, ſo that they ſucceed one another in perfection generally from about December until May.

By the Winter Pears being ſo long acquiring perfection after gathered from the tree, many perſons have thought them fit only for culinary uſes; but moſt of the following liſt are very fine eating Pears, after having lain the proper time to mellow.

*St. Germain Pear.*] A large long yellowiſh-green, extraordinary fine Pear, of the melting ſugary kind: in eating from December until February.

*Chaumontelle Pear.*] A large oblong Pear, having one ſide purpliſh the other of a whitiſh-green colour, is melting, of a very rich delicious flavour: in eating from December until March or April.

*Martin Sec, or Dry Martin Pear.*] A large, oblong, ruſſety-reddiſh Pear, is breaking, ſomewhat dry, but of a fine perfumed flavour: in eating end of November, December and January.

*Colmar Pear.*] A large ſwelling, flat-topped, greeniſh-yellow Pear, ſpotted with yellow; is tender and exceedingly fine flavoured: in eating from December till January or February.

*Spaniſh Bon Chretien.*] A large pyramidal purple and yellow Pear, having many dark ſpots on the purple ſide; is a fine Winter Pear, ready for eating the end of December, continues good near two months.

*Virgoleuſe Pear.*] A large, oblong, greeniſh-yellow Pear, ſometimes browniſh next the ſun, is an excellent fruit: in eating from the beginning or middle of December until the end of January.

*Dauphine Pear.*] A middle-ſized, roundiſh, top-ſhaped, ſmooth, yellowiſh-green Pear, having a melting, ſugary, muſky pulp: in eating the end of November, continuing in perfection all December and moſt part of January.

*Winter*

*Winter Verte Longue Pear.*] A longiſh, green-coloured, ſmooth, ſpotted, exceeding good Pear; in eating the end of December and January, &c.

*Winter Beurre Pear.*] A ſmalliſh, oblong, yellowiſh, red-ſpotted, very fine Pear; ready for eating in December and January.

*Winter Thorn Pear.*] A large, long, pyramidal whitiſh-green Pear; is melting, and in fine eating from December till February.

*Martin Sire, or Lord Martin Pear.*] A large, roundiſh, irregularly-ſwelling, ſmooth Pear, red on one ſide, the other yellow; is breaking and of a perfumed flavour: in eating in December and January.

*Winter Bergamot Pear.*] A middle-ſized, roundiſh, greeniſh-yellow Pear: in eating from the end of November until the ſpring.

*Holland's Bergamot.*] A large, round, greeniſh Pear, having a tender rich pulp: in eating from January till April.

*Winter Bon Chretien.*] A very large, long pyramidal, yellowiſh-green Pear, having often an uneven ſurface; is breaking, very juicy, remarkably ſweet and rich flavoured, and often proves the beſt Winter Pear in the collection: in eating from February till April or May.

*German Muſcat Pear.*] A middle-ſized, oblong, ruſſety-red Pear, having a melting rich pulp: in eating from February till May or longer.

*Eaſter Bergamot Pear.*] A large, roundiſh, flat-topped, greeniſh Pear, having many rough ſpots is of the breaking kind; and is in eating from February till April or May.

*Winter Ruſſelet Pear.*] A middle-ſized, longiſh Pear, red on one ſide, the other of a greeniſh-yellow, is melting and agreeably reliſhed: in eating in January, March, &c.

*St. Martial Pear.*] A longiſh, oblong, ſmooth Pear, one ſide purple the other yellow; having a buttery rich fleſh: in eating from February till May or June.

*Cadillac Pear.*] A very large, roundiſh, red and yellow Pear, having a hard, ſour pulp, but is excellent for baking and other culinary purpoſes: in uſe from November or December till May.

*Union Pear, or Uvedale's St. Germain.*] A large, long, deep-green Pear, reddiſh on one ſide, having a hard, ſour, pulp, but is excellent for baking, &c. in perfection from November or December till May or longer.

*Black Pear of Worceſter, or Parkinſon's Warden.*] A remarkably large, oblong, duſky brown, rough Pear, having a hard auſtere pulp, but is very fine for culinary uſes, from November till March or April.

*Double Flowered Pear.*] The tree produces double flowers ſucceeded by a large, ſhort, yellowiſh and red Pear, rather hard and auſtere; but is remarkably fine for baking, &c.

Other leſs material varieties of Winter Pears are known by the following names.—*Good Lewis*, a large longiſh Pear.—*Ambrette*, a large roundiſh Pear.—*Thick-ſtalked Pear*, a very large roundiſh fruit.—*Amadot*, a middle-ſized oblong Pear.—*St. Auſtin*, a middling oblong Pear.——*Ruſſet of Anjou*, a large roundiſh Pear.—*Chaſſery*, a large oblong Pear.—*Iron-coloured Pear*, a middle-ſized oblong fruit.—*Golden Winter Pear*, a large globular fruit.—*Villain of Anjou*, a large roundiſh Pear.——*Winter Ruſſelet*, a middle-ſized longiſh Pear—*Carmelite*, a middling roundiſh Pear for kitchen uſes.——*Winter Citron-ſhaped Pear*, for baking—*Blood Pear*, for baking, &c.—*Engliſh Warden*, a large Pear for baking and other culinary uſes.

There are many other varieties of Pears of leſs account, both of Summer, Autumn, and Winter kinds, that are unneceſſary to inſert here; and indeed it would be almoſt impoſſible to diſcriminate the various ſorts of hard Pears, and others of little note, found in the orchards and gardens in country villages, and about farm-houſes, in different parts of England, &c.

But as the varieties deſcribed in the above three liſts having known merit, and are cultivated in moſt of the nurſeries for ſale, by the names here prefixed to each kind, conſiſting of near ſixty different ſorts, are more than ſufficient to furniſh the moſt extenſive garden with a copious variety of Pears almoſt the year round.

All the varieties of this tree are hardy and will ſucceed in any common ſoil of a garden or orchard, both as dwarfs for walls and eſpaliers, &c. and in ſtandards of all ſorts; and in all of which modes of training they will bear plentifully: it is however of importance to allot a good wall and eſpalier for ſome of the choicer kinds, both Summer, Autumnal, and Winter Pears, in order both to forward the growth of the fruit and to improve its ſize, beauty and flavour: a ſouth, eaſt, and weſterly wall are the proper expoſures, and it is eligible to plant ſome in each of thoſe aſpects, to vary the times of ripening, though moſt of the Summer Pears will ſucceed very well in almoſt any aſpect, and

if ſome are planted alſo againſt a north-wall they will ripen later and continue the ſucceſſion of any approved ſorts longer in eating; but it is particularly neceſſary to allow all the fine ſorts of Winter Pears an eaſt or weſt wall, or a well expoſed eſpalier, otherwiſe they will not perfect their fruit kindly in unfavourable ſeaſons; in eſpaliers however that are well trained, all the ſorts of Pears attain great perfection, and the eſpaliers may be arranged round the quarters of the kitchen-garden, or in any other free ſituation where the ſoil is of ſimilar quality. See ESPALIERS.

Remarking, that theſe trees, both againſt walls and eſpaliers, ſhould generally be allowed a great deal of room to ſpread, for by having full ſcope they will extend their branches more than twenty feet on each ſide of the ſtem, and the whole will ſometimes form a ſpread of forty or fifty feet, with height in proportion.

Standards of ſome ſorts of Pears are alſo naturally of a very ſpreading growth, others grow more upright.

However in all the methods of training theſe trees it is highly requiſite to allow them ſufficient room to ſpread to their full extent, and their branches ſuffered to extend themſelves always at full length; for Pear-trees ſhould never be ſhortened, except in the firſt or ſecond year, &c. to obtain a ſupply of lateral branches to form a more regular ſpreading head, as hereafter elucidated, becauſe as they always bear their bloſſom and fruit upon ſhort ſpurs ariſing from the ſides of the branches; firſt, however, towards the extreme parts, then by degrees all along the ſides almoſt from every eye, that ſhortening would cut away the firſt fruitful parts, and thus by ſtopping their progreſs of ſhooting in length it would force out ſtrong ſhoots from all the eyes, and prevent their forming ſpurs or fruit-buds; but being trained at full length they ſhoot moderately, and in two or three years naturally form ſhort ſpurs of from about half an inch to an inch or two long, the ſame branch and ſpurs continuing fruitful a great number of years.

But it muſt be obſerved, that Pear-trees are generally ſeveral years, before they attain any tolerable bearing ſtate, for the branches ſeldom begin to form fruit-ſpurs till they are from about two or three, to four or five years old; at that age, however, they ſometimes begin to bear, but never any general crop till they are eight or ten years old.

*Method of Propagation, and general Culture in the Nurſery.*

Pear-trees are propagated by grafting and budding upon any kinds of Pear-ſtocks; alſo occaſionally upon Quince-ſtocks, and ſometimes upon white-thorn ſtocks, but Pear-ſtocks are greatly preferable to all others for general uſe.

The numerous varieties of Pears having been firſt accidently obtained from ſeed, and as ſeedlings of theſe varieties rarely produce the ſame ſorts again; the approved kinds are continued and encreaſed only by grafting or budding upon ſtocks raiſed from the kernels of any kind of Pears, as above ſaid, or occaſionally upon Quince-ſtocks, eſpecially for dwarfs of any ſort, as the Quince being a moderate ſhooter, they moderate the growth of the trees grafted or budded thereon, ſo as to be more eaſily kept within a ſmaller compaſs; and for the ſame reaſon, white thorn ſtocks have been uſed; but theſe being apt to render the fruit drier and ſtony at the core, are almoſt totally diſuſed in the nurſeries; and trees upon Quince ſtocks being of ſhorter duration than upon Pears, they are not now in much repute, ſo that Pear-ſtocks are the beſt of all for general uſe, both for dwarfs and ſtandards: obſerve therefore the method of raiſing Pear-ſtocks is from the kernels of any ſorts of Summer or Autumnal Pears; ſowing them the end of autumn or early part of winter in beds of light earth covering them near an inch deep; they will come up in the ſpring, and in autumn, winter, or ſpring, following, plant out a parcel of the ſtrongeſt in nurſery-rows to remain for grafting and budding, which after having from one to two or three years growth here, or when about half an inch thick, or a little more or leſs, they will be of proper ſize to receive the grafts and buds.

The grafting and budding them is to be performed in the uſual method, performing the grafting in the ſpring and the budding in ſummer: See GRAFTING and INOCULATION: being particularly careful to procure the grafts and buds from ſuch trees as produce the fineſt fruit of the reſpective ſorts you intend propagating.

Being however provided with the grafts and buds, proceed to graft them, &c accordingly for dwarfs and ſtandards; obſerving, that thoſe deſigned as dwarfs for walls, eſpaliers, or ſtandard-dwarfs, be grafted or budded

budded near the bottom; and for half and full ſtandards, the ſtocks may either be previouſly trained up from three or four to ſeven or eight feet high to form a ſtem, then grafted near the top, or may be grafted low in the ſtock, like the dwarfs, and train the firſt main ſhoot for a ſtem the above height; all the grafted trees both dwarfs and ſtandards will ſhoot the ſame year, but the budded ones not till the ſpring after; and when their heads are a year old from the grafting and budding they may if thought proper be planted out for good, or remain longer in the nurſery as may be convenient.

Obſerve however, that the dwarfs deſigned for walls, eſpaliers, &c. whether they remain longer in the nurſery or are tranſplanted at a year old into the garden, ſhould have the firſt ſhoots from the graft or bud when a year old, headed down in March to five or ſix eyes to force out a proper ſupply of four, ſix, or more lateral branches, near the ground to furniſh the wall and eſpalier with bearers quite from the bottom, and theſe will readily produce others to cover the upper part.

But ſtandards, ſuppoſing them to be grafted on high ſtocks, may either be headed near the top of the ſtock, or permitted to run up, as the caſe may require, that if ſhortened it will force out laterals near the head of the ſtem, and form a more ſpreading full head; and if ſuffered to run up with the firſt ſhoots entire, they will form higher, and generally handſomer heads in the end; ſuch ſtandards however that are grafted or budded as low in the ſtock as for dwarfs, muſt have the firſt ſhoot trained upright at full length ſix or ſeven feet high for a ſtem, if for full ſtandards, then may either top it at ſix feet height, to force out laterals near that part to form a ſpreading head as aforeſaid, or ſuffer it to run and branch in its own way to form a more erect and higher head.

All the headed trees however, both dwarfs and ſtandards, that being cut down in the ſpring, will ſoon branch out from all the eyes immediately below; being careful during the ſummer to trim off all ſhoots from the ſtem, and ſuffer all the top ſhoots to remain entire, and they will form handſome heads by the end of ſummer: and in autumn, winter, or ſpring, following, they may have their final tranſplantation into the garden, &c. provided it was not done before heading down.

But if obliged to retain them longer in the nurſery, let the whole be trained agreeable to the form they are deſigned to aſſume, whether dwarfs for walls and eſpaliers, dwarf-ſtandards, or half or full ſtandards, ſuffering the whole to branch away at full length, not ſhortening any after the above general heading down when a year old, except it ſhall ſeem abſolutely neceſſary to procure a more ſufficient ſupply of lower branches, after which however, no further general ſhortening ſhould be practiſed to theſe ſort of trees, for after having obtained a proper ſet of regular branches near the head of the ſtem, they will readily furniſh more in their turn to encreaſe the head upwards.

*Their Tranſplantation into the Garden, &c*

When the trees however are from one or two to four or five years old, from the graft or bud they are of a proper growth for planting out finally; but if larger trees are required, thoſe of ſix or eight years old may be ſafely tranſplanted; younger trees, however, always ſucceed the beſt, even if only two or three years old.

The ſeaſon for planting them may be any time in open weather from the end of October till March; but if in autumn, or early in winter it will be an advantage.

They will ſucceed in any common ſoil of a garden, or any good fertile orchard-ground, or field, that is not copiouſly wet, or very ſtiff or ſtubborn, but moderately light and pliable, one good ſpade, at leaſt, if more the better; preparing the ground by proper trenching one or two ſpades deep, as the depth of good ſoil admits; and to dig capacious holes for each tree at eligible diſtances.

*Firſt of Planting the Dwarfs and their general Culture.*

The diſtance to plant Dwarf-Pears for walls and eſpaliers is not leſs than twenty feet, but if twenty-five or thirty, or more the better, eſpecially if lowiſh walls, &c. that in default of height, there may be full ſcope to extend their branches conſiderably in a horizontal direction, as they will effectually fill that ſpace, or even much more if allowed it them; but the above diſtance of thirty or forty feet appearing very conſiderable at firſt, and the trees ſtanding ſo wide having a ſtraggling appearance for ſeveral years before they approach one another to effect any uniformity, they are rarely planted at that diſtance, ſome ſcarcely half ſo much, but ſeldom more

than

than twenty or twenty-five feet; however, it is of importance to grant theſe trees ſufficient room; and the higher the walls the better, which is of particular advantage to Pears, evident by thoſe growing againſt the ends of high buildings, as they extend themſelves very conſiderably every way, as before obſerved, and their branches requiring to be trained conſtantly at full length, in which they will emit fruit-ſpurs all the way along their ſides; therefore they may be planted at leaſt from twenty-five to thirty feet diſtance, and in each interval may plant a cherry, or any other moderate-ſhooting fruit-tree, to fill the vacancy, and bear a few years, till the Pears advance in growth; and according as theſe approach one another, cut the others away by degrees, ſo as at laſt the Pears may occupy the whole ſpace. Having however fixed on the diſtance, and the holes dug, and the trees ready, let them be planted in the uſual way, and all with their heads entire, at leaſt for the preſent. See PLANTING.

The trees being thus planted, their general management, with regard to training and pruning, is nearly as follows.

Obſerve, in the firſt place, that if the young trees thus planted are only one year old from the graft or bud, having their firſt ſhoots of a year-old entire, theſe ſhould in the ſpring be headed down to five or ſix inches, as directed in their nurſery culture, to force out lower horizontals; but if they were previouſly headed in the nurſery, as we adviſed, and having thereby thrown out laterals to form a regular ſet of horizontals, conſiſting of ſix or more regular branches near the bottom, they ſhould not now be ſhortened, but trained to the wall or eſpalier at full length horizontally, preſerving an equal number on each ſide five or ſix inches aſunder, they will readily emit a further ſupply of horizontals to cover the wall, &c. regularly upward, and at the ſame time as being not ſhortened, they will gradually form themſelves for bearing, as every ſhortening of the branches of theſe trees retards their bearing a year at leaſt; if however there is a want of branches, ſome of the middlemoſt may be pruned ſhort, and trained upright. According as the trees ſhoot in ſummer, train in a farther ſupply of all the regular ſhoots in every part where they occur, at full length, unleſs it ſhall ſeem neceſſary to pinch ſome ſtrong ſhoots to obtain a greater ſupply of horizontals the ſame year, in order to furniſh the head as ſoon as poſſible: at this time however, diſplace all fore-right and other irregular growths of the year, continuing the ſupply of regular ſhoots cloſe to the wall, as they advance in length during their ſummer's growth. And in the winter pruning, examine the ſupply of ſhoots retained in ſummer, ſelecting all thoſe that are well-placed and properly ſituated for training in, to increaſe the number of horizontals regularly on each ſide, which leave wholly entire, and at the ſame time retrench any ſuperfluities and ill-placed ſhoots omitted in ſummer; then let the whole ſupply of regular horizontals in every part be trained in ſtraight and cloſe to the wall and eſpalier, horizontally and equally on both ſides of the tree, every branch at full length, five or ſix inches aſunder, as aforeſaid. See WALL and ESPALIER TREES, PRUNING, &c.

Another method ſometimes practiſed in training theſe trees for walls and eſpaliers is, that after their firſt heading down, and having thrown out ſeveral laterals, ſelect three of the ſtrongeſt and moſt regular-placed of them, one on each ſide and one in the middle, nail the two ſide ones horizontally at full length, and the middle one upright; next year the tree having produced a further ſupply of ſhoots, add two or four of them as ſide-horizontals, arranging them on each ſide of the ſtem as the two former, training the middle ſhoot ſtill in an upright direction; obſerving, however, if it ſhould not furniſh horizontals low enough, it may be ſhortened ſo as to make it throw out ſhoots at any requiſite height, continuing the middle one always upward for a ſtem, and the ſide ones horizontally for bearers.

By either of the above methods of training theſe trees, continue every year increaſing the number of horizantals, till the allotted ſpace of walling and eſpalier is regularly covered with bearers at equal diſtances, ſtill continuing them all at full length in all future training, as far as the ſcope of walling, &c. will permit; and they will all naturally form fruit-ſpurs at every eye, almoſt their whole length, and the ſame branches continue in a fruitful ſtate a great number of years.

In the general training of theſe trees, let it always be remembered, that all branches trained in for bearers muſt never be ſhortened, becauſe, as we before obſerved, their fruit-ſpurs being generally produced firſt towards the end, then gradually along the

ſides of the branches, of from two or three to twenty years growth or more, ſo that there is no need of ſhortening to procure a new ſupply of bearing wood annually, as in peaches, nectarines, and ſuch other trees as bear fruit upon the young wood only; but in Pears the ſame branches not only continue for years in a bearing ſtate, but become every year more and more fruitful even to a great age, if not retarded and ſpoiled whilſt in training by ſhortening, as is very often the caſe; for ſhortening theſe ſort of trees, both ſtops their progreſs of growth and bearing, by reducing the length of the branches conſiderably, and cutting away the firſt fruitful parts, as they generally bear fruit at or near the extremity; and by reducing their length it forces out numerous, ſtrong, uſeleſs ſhoots from the eyes below, at the places where fruit-buds would have been otherwiſe formed, and inſtead thereof crowd the tree with a great redundancy of unneceſſary wood, and but little fruit; but by training the bearers from the firſt at full length, and continued ſo as far as the allotted ſpace will poſſibly allow, they not only ſooner fill the ſpace of walling, &c. but emit fruit-buds from almoſt every eye, and bear abundantly.

When the trees have once thus filled the wall or eſpalier with branches, they need but very little farther ſupply for many years, and that only occaſionally, according as any worn-out or decayed branch occurs, and wants renewing with young wood. See PRUNING.

But two prunings every year are requiſite to preſerve their regularity and bearing ſtate, a ſummer and a winter pruning

The ſummer pruning ſhould be begun in May, or early in June, and rub off all the ſuperfluous and unneceſſary ſhoots of the year, and all fore-right and other ill-placed ſhoots, retrenching them quite cloſe, being careful to leave the terminating ſhoot of every horizontal or bearer entire; and reſerve here and there a well-placed ſhoot towards the lower parts in particular, where there are any apparent vacancies, or if none, it is proper to retain ſome ſhoots as above, till winter pruning, and if then not wanted, can be eaſily retrenched, training them in for the preſent at full length.

The winter pruning may be performed any time from the fall of the leaf until March; in this pruning examine the branches in general, and ſee if they are any where too much crowded, or are trained irregularly; and if they are, let them be regulated as they may require; at the ſame time examine if there are any vacancies; and in which caſe train ſome contiguous ſhoots reſerved in the ſummer dreſſing, to ſupply the deficiencies; all other ſhoots trained in laſt ſummer, not now wanted to ſupply any vacant ſpace, muſt be cut clean out cloſe to the branches, being careful ſtill to preſerve the terminating ſhoot of every branch entire, likewiſe all the fruit-ſpurs in every part, and faſten in all the branches regularly at full length.

But in winter-pruning old trees however, decayed and worn-out branches will ſometimes occur; be careful therefore to cut out all decayed wood whereſoever it appears, training young, if poſſible, in its ſtead; likewiſe where any branch, either through exceſſive age or bad management, is become barren or worn out, let it either be retrenched to ſome eligible lower young branch or ſhoot, or may previouſly have young bearers in training a year or two or more from the bottom between the main horizontals, which is eligible enough in old trees, when there is any apparent vacancy happening either by decayed wood or worn-out branches, and according as the young ones aſſume a bearing ſtate, retrench the bad wood, and train the young ſupply in its place; in this caſe look always well to the bottom of your trees, and if any good ſhoots offer where there is an appearance of a vacancy like to happen, train them up between the main branches to be advancing to a bearing ſtate, to be ready when wanted.

Where any of the choicer ſorts of theſe trees have, through great age or bad culture, become infirm, their branches in general worn out, and not furniſhed with bearing wood, we ſhould endeavour to renew them with young bearers, by heading the branches wholly down near the bottom; in winter or ſpring, they will break out in the old wood, and in the following ſummer furniſh a large ſupply of ſtrong young ſhoots, which train agreeable to the rules before laid down, and they will ſoon form a new tree, as it were, and bear plenty of good fruit.

After each winter-pruning of all theſe trees againſt walls and eſpaliers, they will require a general nailing, &c. let this always be done with great regularity, training all the branches horizontally as ſtraight as poſſible their whole length, at equal diſtances. See WALL TREES, ESPALIERS, &c.

As

As to dwarf ſtandards of theſe trees, ſee their mode of training, &c. under the article DWARF TREES.

The culture of the borders wherein theſe wall and eſpalier Pears are growing is, common digging once every year at leaſt, and with the addition of manure occaſionally in common with the other parts of the garden; though if ſome good rotten dung is applied every other year, and the ground well dug or trenched every winter, it will greatly promote the ſize and perfection of the fruit.

*Planting them for Standards and general Culture.*

Standards of any ſorts of Pears bear plentifully in any open ſituation, though the fruit may not always be ſo large and fine as thoſe of wall and eſpalier trees: ſummer and autumn Pears however ripen in great perfection on ſtandards. Obſerve in planting them, that trees of from two or three to four or five years old, having tolerable heads, are of a proper age and ſize for planting, and are preferable to older trees for any general plantation. See PLANTING. And that having been trained as directed in their nurſery culture, and formed heads, conſiſting of ſeveral branches, let them be planted with all their heads entire, except retrenching any very irregular-placed branch, but retain all the others, and ſuffer them to remain at full length, and plant them in the uſual manner of tree-planting. See PLANTING.

In their future growth, ſuffer them to branch away as faſt as they are able, according to nature, and they will ſoon form large branchy heads, ſuffering all their branches to remain entire, and extend themſelves in length, and they will all emit numerous fruit-ſpurs, and bear plenty of fruit.

The general culture of ſtandard Pears, in reſpect to pruning, is very trifling, and that only required occaſionally, probably once only in ſeveral years; ſuch as the retrenching any very irregular growing branch, ſuch in particular as grow croſs-ways, and greatly incommode the neighbouring branches, alſo to thin ſuch branches that are very much crowded, and confuſe the head conſiderably; all decayed wood and ſuckers from the root and ſtem. See PRUNING, article *Pruning Standards.*

Where theſe ſtandard trees are ſituated in a garden, having the ground well trenched every year, and occaſionally enriched with dung, they generally produce finer fruit than in orchards.

*Gathering and preſerving the Fruit.*

The maturity of Pears, after arriving to full growth, is generally known by their changing from a green to a yellow or reddiſh colour, &c. and by their frequent falling from the tree, and when with a gentle twiſt or turn up, eaſily quit their hold; but thoſe tokens are more particularly obſervable in ſummer and autumn Pears; for winter Pears being not near ripe when gathered, often require a good pull before they quit the branches.

Summer Pears ripen in ſucceſſion in different ſorts, from about the beginning or middle of July till the middle of September; many of the earlieſt ripen all at once, as it were, and continue good but a few days, either on the tree or when gathered, nor will any of the ſorts keep good long; and none of the ſorts ſhould hang on the tree till full ripe, otherwiſe moſt of them will be mealy and inſipid; let theſe ſorts therefore be gathered as ſoon as they are arrived to full growth, and juſt begin to colour and diſcover maturity, but before they become ſoft and mellow; obſerving that for family uſe, they may be gathered from the tree according as they attain perfection; but let the general crop of each ſort be always taken down before they ripen fully, and lay them in any dry room; none of the kinds will keep long, ſome only a few days, and ſcarcely any of them a fortnight, though from different varieties ripening at different times, the ſucceſſion is continued for eight or ten weeks.

Autumn Pears ripen in different varieties, from about the middle of September till the end of October; ſome of the forwardeſt ripen eatable on the tree, others requiring to lie ſome time after being gathered before they acquire perfection. Let the different ſorts of this claſs of Pears be gathered according as they arrive to maturity; thoſe deſigned to keep ſome time ſhould be gathered juſt when they have attained full growth; their maturity or full growth on the trees is known by their frequent dropping, and by their readily quitting the tree on being handled: gather them in dry weather, and lay them in a dry cloſe room, or in baſkets, each ſort ſeparate; they will thus gradually mellow, collect rich juices, and delicious flavour.

Winter Pears attain their full growth on the trees about the end of October or beginning of November, but the eatable kinds do not acquire maturity for eating on the tree, nor for ſome conſiderable time after they are gathered, ſome probably in a month, others two or three, and ſome more, and ſome ſorts not till ſpring following, and often continue in perfection till ſummer, as is noticed in the deſcription of the different ſorts of winter Pears; but the baking kinds may be uſed any time from November during their continuance.

All the Winter Pears however ſhould be indulged with as full growth on the tree as the weather will permit, even until the end of October or firſt or ſecond week in November, for the later kinds, if the ſeaſon continues mild; be cautious however to get them gathered before attacked by much froſt.

In gathering all ſorts of Pears for keeping, always chuſe dry weather, and when the fruit is alſo quite dry.

The method of gathering theſe fruit is to pull one and one by hand, by a gentle twiſt, or turn upward, and if they readily ſeparate, it is a ſign of full growth, more particularly the ſummer and autumn Pears; being particularly careful in gathering not to bruiſe them, and let each ſort be kept ſeparate.

According as they are gathered, carry them directly into the fruitery rooms, where thoſe intended for long keeping, ſuch as the late autumnal and all the winter Pears, ſhould be previouſly laid up in heaps, and covered with cloths, in order to promote a perſpiration, and diſcharge the watery moiſture, which prepares them for keeping, as well as improves their flavour: this fermentation or ſweating will be effected in a week or fortnight, when they ſhould all be wiped dry with a woollen cloth; then let a quantity be depoſited upon the ſhelves of the fruitery, to remain for firſt eating; others, for longer keeping, pack up in baſkets, thickly lined within with ſtraw, then ſome thick paper; and having filled the baſket with the Pears, cover them down alſo with paper, then a good thickneſs of ſtraw over all, faſtening the whole as cloſe down as may be, tying a label, with the name of the fruit and time of ripening, to each baſket, and then place them in a cloſe warm room; they will thus ſucceed thoſe on the ſhelves for uſe, and keep good a long time; and if ſome are alſo put into large earthen jars, plugged and roſined down perfectly cloſe to exclude the external air, they will keep a long time ſound, eſpecially the lateſt ſorts, which will keep till May or June.

They ſhould be occaſionally looked over, to remove all ſuch as aſſume any tendency to decay, before they ſpread the putrefaction to the adjacent fruit; this ſhould be properly attended to at intervals, to thoſe on the ſhelves or any where in the open fruitery in particular, as they are more liable to putrefaction, and can be eaſily examined; but thoſe packed up in cloſe baſkets, &c. are not ſo eaſily obſerved, nor will they require it ſo often; it is however proper, after ſome conſiderable time, to look them over.

*Apple Kinds.*

PYRUS *Malus.*

The Apple-tree (*Malus*) being now conſidered as a ſpecies of *Pyrus*, as formerly obſerved, we have arranged it accordingly under that head, together with all its varieties, which are exceedingly numerous in the difference of the fruit: ſome for eating, others for baking, boiling, cyder, &c. and may be ſaid to be the moſt valuable fruit in the world for its various œconomical uſes, and long continuance in perfection, which, in different ſorts, is the year round.

Claſs, order, and characters, are the ſame as the *Pyrus Communis.*

Of the Apple kind there may be reckoned two ſpecies, viz. Common Apple-tree, compriſing many varieties—Sweet-ſcented Virginian Crab, two varieties.

The ſpecies are,

1. PYRUS *Malus.*

*Malus, or Common Apple-tree.*] Grows twenty or thirty feet high, having oval, ſerrated leaves, and ſeſſile umbels of whitiſh-red flowers, ſucceeded by large, roundiſh, and oblong fruit, concave at the baſe.

*Varieties.*] The varieties of this ſpecies are amazingly great, in reſpect to the differences of the fruit; and the botaniſts contend that the Wilding, or Crab-Apple of the woods and hedges, is the original kind, and from the ſeed of which the cultivated Apple was firſt obtained; whoſe varieties, no doubt, are multiplied to ſome hundreds, in different places, having been all firſt accidentally obtained from the ſeed or kernels of the fruit, and the approved ſorts continued and increaſed by grafting upon Crabs or any kinds of Apple-ſtocks; but although the number of different varieties is very conſiderable, there are not

not above forty or fifty ſorts retained in the nurſerymen's catalogues as principal fruit, which however is fully ſufficient to furniſh a ſupply of Apples all the year. The different varieties arrive to full growth in ſucceſſive order, from July till the end of October; the ſummer kinds, that ripen before the middle of September, are many of them in eating immediately from the tree, and do not keep long: but moſt of the autumn and winter kinds, that ripen from the middle or end of September till the end of October, improve in perfection after being gathered, as they lie in the fruitery; and many of the winter kinds in particular keep good many months, even until the arrival of Apples next ſummer.

The moſt noted varieties are generally known by the following names, &c.

*Genniting, or June-eating Apple.*] A ſmall Apple, oblong and roundiſh in different varieties, of a moſt agreeable flavour, and valuable for its early perfection, being in eating ſometimes in June, againſt a wall, but ripens principally in July.

*Margaret Apple.*] A middle-ſized, oblong Apple, one ſide tinged with red, the other pale green, and is highly flavoured; ripe for eating in July and Auguſt.

*Common Codlin.*] A largiſh, irregular, greeniſh-yellow Apple, tinged with red, valuable for its early growth, being fit for many culinary purpoſes, from June till Auguſt and September, and is alſo a tolerable good eating Apple when arrived to maturity: ripens fully in Auguſt, becoming of a bright yellow and red colour.

*Kentiſh Codlin.*] A large, longiſh, irregular Apple, excellent for culinary uſes, in Auguſt and September.

*Summer Pearmain.*] A middle-ſized, oblong, fine, red-ſtriped Apple, good for eating and culinary uſes: ripe in Auguſt and September.

*Scarlet Summer Apple.*] An oblong, deep-red, beautiful Apple, for eating and kitchen purpoſes, in Auguſt and September.

*Summer Calville.*] A large, fine, ſummer Apple: ripe end of Auguſt and September.

*Quince Apple.*] A ſmall, roundiſh, quince-ſhaped, ruſſet and yellow Apple; ripe for eating in Semptember.

*Summer Rembourge.*] A large, handſome, variegated red and yellow Apple: ripe in Auguſt and September.

*Loan's Pearmain.*] A middle-ſized beautiful Apple, having one ſide finely reddened, the other variegated alſo with red: ripe in September and October.

*Royal Pearmain.*] A large, oblong, beautifully reddened Apple, for eating and culinary uſes: ripe in September and October.

*Red Autumn Calville.*] A moderately-large, oblong, fine-red Apple, of a vinous aromatic flavour: ripe in autumn.

*White Autumn Calville.*] A large, oblong, fine-eating Apple: ripe in autumn.

*Golden Ruſſet.*] A roundiſh, middle-ſized, ruſſet-yellow, good eating Apple: ripe about autumn.

*Golden Rennette.*] A middle ſized, roundiſh, beautiful, red and yellow Apple, having a firm fine-flavoured pulp, excellent both for eating and baking, &c. ripe in October, and continues till ſpring, if packed up cloſe.

*Golden Pippin.*] A ſmall, roundiſh, and oblong, beautiful-yellow Apple, firm, and admirably fine flavoured: ripe in October, and may be kept till the ſpring.

*Courpendu, or Hanging Body.*] A large, oblong, handſome Apple, red next the ſun, the other ſide pale, and generally hangs downward: in eating in autumn and part of winter.

*Grey Leadington Apple.*] A longiſh, moderately large, greyiſh-green, very fine Apple, being a moſt excellent table fruit: ripe in autumn and part of winter.

*Aromatic Pippin.*] A middle-ſized, roundiſh Apple, one ſide ruſſet-coloured, the other yellowiſh, is of an agreeable aromatic flavour: ripe for eating in October, keeping good a long time.

*Violet Apple.*] A largiſh, oblong Apple, one ſide reddened, the other variegated, having a firm ſweet pulp, flavoured like violets: ripe in October, &c.

*White Rennette.*] A large, roundiſh, whitiſh-green Apple, having a firm ſugary pulp, good both for eating, and for baking and boiling: ripe end of October, continuing good till January.

*Rennette Griſe.*] A roundiſh, middle ſized Apple, grey-coloured on one ſide, the other tinged with yellow; in fine eating from October till Chriſtmas or longer.

*Winter Pearmain.*] A moderate-ſized oblongiſh Apple, red on one ſide, the other variegated red and yellow; is tolerable for eating, but very good for boiling: ripe end of October, continuing good all winter.

*Kentiſh*

*Kentiſh Pippin.*] A large, oblongiſh, whitiſh-green Apple, good for eating, but particularly adapted for the kitchen uſes, from October till ſpring.

*Nonpareil Apple.*] A middle-ſized, roundiſh, ſomewhat-flatted, duſky-ruſſet-green Apple, having a firm pulp, replete with a ſharp agreeable juice; a moſt excellent winter fruit for the deſert; in eating from November or December until May.

*Large Nonpareil.*] A large, round, light-ruſſet and yellowiſh Apple; is a fine handſome fruit, but does not continue in perfection ſo long as the common Nonpareil; in eating from November or December till March.

*Holland Pippin.*] A large, oblong, greeniſh Apple, having the eye pretty much ſunk; is tolerable for eating, but is in great eſtimation for culinary purpoſes, from October until March or April.

*Monſtrous Rennette.*] A remarkably-large oblong Apple, one ſide red, the other green, valued chiefly for baking or boiling; in November and December, &c.

*None Such Apple.*] A roundiſh beautiful Apple, being finely tinged with red on one ſide; is highly flavoured, and excellent both for eating and culinary uſes: ripe about autumn, and continues till the end of December.

*Royal Ruſſet.*] A fine, large, roundiſh-oblong, deep-ruſſet-coloured, rough Apple, having a ſoft, yellowiſh pulp, of a mild flavour, and is admirable for all culinary uſes in particular; is in perfection from October or November until April.

*Embroidered Apple.*] A moderately-large, beautiful Apple, adorned with broad red ſtripes; is a middling fruit, both for eating and kitchen purpoſes, and is in perfection in winter.

*Wheeler's Ruſſet.*] A middle ſized, roundiſh flatted, ruſſet-coloured, and yellowiſh Apple, having a firm, briſk, agreeably reliſhed pulp, both for eating and culinary uſes, and is in perfection all winter and ſpring.

*Pile's Ruſſet.*] A ſmaller, middle-ſized, oblong-oval Apple, ruſſet-coloured on one ſide, green on the other, having a very firm fleſh, of a ſharp acid reliſh; is by ſome eſteemed for eating, but is in high repute for baking, continuing in perfection all winter until April or May.

*Stone Pippin.*] A pretty large, whitiſh, very hard Apple, having a ſour unpleaſant pulp eaten raw, but is in good eſtimation for baking; is in perfection all winter, ſpring, and great part of ſummer.

*Barnard's Baking Apple.*] A very large, fine, baking Apple, in perfection in winter, and keeps good all ſummer.

*Kitchen Rennette.*] A large handſome Apple, in high repute for all culinary uſes: in perfection all winter.

The above varieties being the moſt approved ſorts, they are cultivated in moſt of the nurſery-gardens for ſale.

The following are leſs material varieties of eating and culinary Apples mentioned in ſome fruit catalogues,—Summer Ruſſet, a roundiſh, ruſſet-coloured Apple—Summer Pippin, a roundiſh yellow Apple—L'Api, a ſmall bright-red Apple—Tranſparent Apple, having a pellucid pulp——Virgin Apple, long and beautifully red—Aniſe Apple, longiſh, and flavoured like aniſeed—Gilliflower Apple, middle-ſized, and delicately reddened—Salmon Apple, longiſh, red, and yellow fruit—Margil Apple, middle-ſized, ridged, and red-ſtriped—Kirton Pippin, roundiſh, and often cracked—Lemon Pippin, ſmall, roundiſh, yellow fruit—Aclemy Ruſſet, a roundiſh, ruſſet-coloured Apple——Gray's Pippin, large, roundiſh, grey, and green Apple—Winter Greening, a very large green Apple—Black Pippin, a large dark-green Apple—Partridge Apple, a large kitchen Apple—Lord Iſlay's Pippin, a middling roundiſh Apple—Spencer's Pippin, a middling, round, browniſh and yellowiſh-green Apple—Winter Pippin, a roundiſh firm Apple—Coſtard Apple, large, irregular, and red ſtriped—Winter Rambour, a large, round, red Apple—Cat's-head Apple, very large, for culinary uſes. Of the above, the firſt five or ſix ſorts are forward Apples, and all the others are autumn and winter fruit, and moſt of which may be uſed occaſionally for eating and kitchen uſes.

And of Cyder Apples, the following are the principal ſorts—Redſtreak Apple—Royal Wilding—Everlaſting Hanger——Gennet Moyle—Whitſour Apple—John Apple—Woodcock Apple—Herefordſhire Underleaf—which, with many others, are well known in the cyder counties, as Devonſhire, Herefordſhire, &c.

To the above liſts may alſo be added the following varieties, being all off-ſpring of *Pyrus Malus.*

*Fig Apple.*] Having been formerly ſuppoſed that the trees produced fruit without any previous

vious visible flower, like the Fig-tree, it obtained the name *Fig Apple*; but the fact is, the tree certainly produces flowers, that are visible, which however are almost apetalous, or without petals, so are not conspicuous like those of the other varieties, but are nevertheless furnished with the generative organs, succeeded by proper fruit.

*Paradise Apple.*] A low weak-shooting tree, of a shrub-like growth, produces small fruit of no value, so is retained in some gardens for variety, and is sometimes used as stocks on which to graft other Apples, to render them of a very dwarfish growth for small gardens, and for planting in pots for curiosity.

*Dutch Paradise Apple.*] Grows a little stronger than the former, and is often used for stocks to graft upon to form dwarf trees for small gardens.

*Wilding, or Crab Apple.*] The tree grows more than twenty feet high, producing small, roundish, and oblong yellow fruit, intolerably sour, harsh, and disagreeable to the taste, so are used only for making verjuice. The trees of this variety grow wild in England, &c. in woods and hedge-rows, and are rarely cultivated in gardens, except for stocks on which to graft the cultivated Apples, for which purpose they have great merit, as trees grafted on Crab-stocks are generally very hardy and durable; sometimes, however, a few plants are introduced in the shrubbery plantations for variety, and are employed by the farmers for making field hedges, as being of quick growth, soon run up, and form a hedge expeditiously. See HEDGES.

Thus far terminates our list of the varieties of this great species *Pyrus Malus*.

There are however, besides the above, many other varieties of less value, but those of the above list are the generally known approved sorts; all the varieties, good and bad, are the off-spring of this one species (*Pyrus Malus*), the trees of all the sorts having oval sawed leaves, and sessile umbels of flowers, appearing in April and May, upon short spurs on the sides and ends of the branches, succeeded by fruit soon after, growing to perfection in different sorts, from July until the end of October, as before observed; those however that ripen before the middle of September keep but a short time, some of the forwardest probably not above a fortnight, others a month, or but little more; but the winter kinds continue in succession several months, and if a quantity of the latest are packed up close in baskets, lined with straw, to exclude the air, they will continue sound and good till next summer.

The following species and variety are American shrubs, retained here in shrubberies for diversity.

²PYRUS *Coronaria.*

*Sweet-scented Crab of Virginia.*] Grows twelve or fifteen high, having angular, serrated leaves, pedunculated umbels of whitish-red sweet-scented flowers, succeeded by small round Crabs, remarkably sour and austere.

*Variety.*] Evergreen Virginian Crab-tree.

Both the varieties are continued distinct by grafting, or by layers or cuttings.

*General Observations on the common Apple-tree.*

The trees of all the varieties of the Common Apple bear well in any mode of training, such as in espaliers, against walls, and all kind of standards; they however are rarely indulged with walls, as all the sorts of Apples attain full perfection without that aid, the walls being commonly reserved for such tender fruits as stand more in need of their assistance; in espaliers, however, it is eligible to have a collection of the choicer sorts, as in this mode of training the fruit generally attain greater perfection as to size, beauty, and flavour, than in standards; but all the varieties likewise acquire good perfection on standards of all sorts, though in a less degree; and it is from common high standards that the general supply of Apples is obtained for common use, and for the supply of markets, making cyder, &c.

In espaliers the trees may either be arranged by themselves, or in assemblage with Pears, &c. alternately, to effect the greater variety, being generally arranged around the outer boundaries of the quarters of the kitchen-garden, in the borders verging the main walks; but some may also be arranged in any other department, either for the sake of variety or convenience. See ESPALIERS.

And in common standards they may be both disposed in ranges thinly in the garden, and formed into orchards, according to the supply required; and in the cyder counties they plant them out in large fields, in wide ranges, to admit of having crops of corn, &c. between; but in common orchards they are planted about thirty or forty feet distance, and the ground is generally laid down in grass. See ORCHARDS.

Dwarf standard Apples are sometimes raised, a few for variety or curiosity, and if

if properly trained, will bear in very great perfection. See DWARF TREES.

The mode of bearing of all the varieties of Apples is principally upon ſhort ſpurs, iſſuing from the ſides of the branches of from two or three to many years old, as obſerved of Pears and plums, &c. formed firſt towards the extremity of the branches, then by degrees along the ſides, provided the branches are always trained at full length, as adviſed for other trees that bear chiefly upon ſpurs, as ſhortening promotes luxuriancy, and forces out numerous ſtrong wood ſhoots in the places where fruit ſpurs would have been formed; but being trained always entire, they aſſume a moderate growth, and gradually emit natural ſpurs in every part; and as the ſame branches and ſpurs remain fruitful many years, determines, that in the general courſe of training and pruning theſe trees, we ſhould not ſhorten their branches, except occaſionally in the firſt and ſecond year after grafting, if thought neceſſary, to force out lower laterals to give the head its firſt proper form; afterwards, permit the branches to extend generally at full length, both in eſpaliers, &c. and all manner of ſtandards, and thus they will all ſoon form a bearing ſtate.

Apple-trees often begin bearing at two or three years old, and at ſix or eight will bear in tolerable plenty according to their ſize.

*Method of Propagation, &c.*

All the varieties were firſt accidentally obtained by raiſing them from the kernels of the fruit, but we cannot depend upon ſeedlings to continue the ſame ſort of fruit.

Grafting therefore is the mode of propagation to increaſe and continue the different varieties the ſame; performing it upon Crab, or any kind of Apple ſtocks, raiſed from kernels, both for dwarfs and ſtandards; alſo upon Codlin and Paradiſe Apple-ſtocks, raiſed from cuttings and layers, when deſigned to have eſpaliers and other dwarf trees, as low as poſſible, to be confined within a moderate ſpace, or for ſmall gardens: ſome ſorts of Apples may alſo be raiſed by layers and cuttings, particularly the common Codlin, which may likewiſe be raiſed from ſuckers, from the root and ſtem of ſuch trees that are wholly of the Codlin kind quite from the root; however, the beſt general method of propagating all the kinds of Apples is by grafting upon the proper ſtocks, as aforeſaid.

The method of raiſing the different ſorts of ſtocks for the above purpoſe is, the Crab and Apple-ſtocks are raiſed from the kernels of the fruit; but the Codlin and Paradiſe-ſtocks muſt be raiſed by cuttings and layers, to continue them with certainty of the ſame kinds and moderate growth: however, as to the Crab and Apple-ſtocks, they may be raiſed from the kernels of any of the ſorts, procuring the kernels in autumn or winter, either from rotted fruits, &c. or from ſuch as have been preſſed for verjuice and cyder, clearing them from the groſſeſt of the pulp; then ſow them in beds of light earth, moderately thick, either all over the bed, or in drills, covering them full half an inch deep; they will come up in the ſpring, when, if the ſeaſon proves dry, water them occaſionally, which will greatly forward the ſeedlings and ſtrengthen their growth, and in autumn, winter, or ſpring following, they may be planted out in nurſery rows, previouſly ſhortening their tap-roots, and planting them in lines two feet and a half aſunder, to remain for grafting; and after having from one to two or three years growth here, they will be fit for grafting, particularly for dwarfs, or even for full and half ſtandards, if intended to form the ſtem from the graft, which is an eligible method for theſe trees; but if the ſtock is to form the ſtem, they will require three or four years growth, to riſe to a proper height, ſeven feet for full, and four or five for half ſtandards.

The work of grafting all the ſorts is the ſame as for other fruit trees, and ſhould be performed in March, either by whip-grafting, cleft-grafting, &c. according to the ſize of the ſtock. See GRAFTING.

Having however provided proper grafts of the different ſorts of Apples you intend to propagate, then let thoſe ſtocks deſigned for dwarfs of all ſorts be grafted within ſix inches of the ground; and ſtandards may alſo be grafted low, and one ſhoot from the graft trained up for a ſtem, or may be grafted on tall ſtocks, inſerting the grafts at ſix feet high: the grafts of all the ſorts will ſhoot the ſame year, and by the autumn following the trees having formed little heads, conſiſting of two, three, or four ſhoots, may then be tranſplanted finally into the garden and orchard, or may be retained a year or two, or longer, in the nurſery, as occaſion may require, obſerving however to train them for the purpoſes intended, ſuch as dwarfs for eſpa-

eſpaliers, &c. and uprights for ſtandards, heading the dwarfs down in March following, within ſix inches of the graft, to force out more laterals below to form a fuller head, proceeding immediately near the bottom, ſo as to fill the eſpalier, &c. equally with branches, quite from within ſix or eight inches of the ground, regularly upward. But as to ſtandards, thoſe grafted low muſt conſequently be trained with one ſhoot upright, at full length, for a ſtem, ſix feet high at leaſt before it is topped; though if grafted on tall ſtocks of height ſufficient for a ſtem, the ſhoots from the graft may either be headed to five or ſix eyes, if you would have them form a more ſpreading head, or may remain entire, and aſpire more in height, and aſſume a more upright pyramidal growth: in all the modes of training, be careful to keep the ſtems clear from all lateral ſhoots, diſplacing all ſuch as ſoon as they appear, and encourage only a proper ſet of branches at top to form the head.

When theſe trees, however, have heads from one to two or three years old from the graft, they are of a proper age for final tranſplantation; though trees of four or five years old will alſo ſucceed very well, and even trees of ſix or eight years growth may alſo be ſafely tranſplanted if required; but younger trees generally grow better and make more progreſs in the end.

The public nurſery-gardens are generally well furniſhed with all the varieties of theſe trees for ſale, either quite young from the graft, or trained trees of ſeveral years growth, at very moderate prices.

The ſeaſon for planting them is, any time in mild weather, from the end of October till March; but if planted in autumn, or early in winter, they will fix themſelves more firmly before attacked by the drought of the following ſummer.

They will ſucceed in any common ſoil of a garden and orchard, and in any free ſituation, except in low very moiſt land, in which they are apt to canker and ſoon go off: in a pliable loam they are generally very ſucceſsful: be, however, in no great anxiety about the ſoil, any middling ſoil of a garden, orchard, or field, not too wet, will do very well, being properly prepared, by good trenching, where the ranges of trees are to ſtand.

*Firſt, of planting them in Eſpaliers.*

Eſpalier Apple-trees ſhould be ranged at not leſs than twenty feet diſtance; but if twenty-five or thirty feet, it will be more eligible, eſpecially for trees grafted on crab or apple-ſtocks, which being free ſhooters, their branches will readily fill that ſpace. However, as to trees grafted on codlin and paradiſe-ſtocks, eighteen or twenty feet may be a ſufficient diſtance; though the latter in particular, is ſometimes planted only twelve or fifteen feet aſunder, as being a very moderate ſhooter: it is, however, adviſable to allow every ſort full room enough, according to their growth, to have room to extend their branches always at full length; obſerving, as the trees having been headed down in the nurſery, and thereby produced laterals forming tolerable heads of ſeveral regular branches, they ſhould now be planted with all their ſaid heads entire, only retrenching any very irregular growth, that do not range conſiſtent with the intended form, and prune any broken roots, then having opened a capacious hole for each tree at the above diſtances, proceed to plant them in the uſual manner as explained in the article *Planting*, being careful to place them with their branches ranging the way of the eſpalier, then let all the branches be trained in horizontally to the right and left, an equal number on each ſide, all at full length, five or ſix inches aſunder, and according as they ſhoot in ſummer ſtill continue them along entire; at the ſame time train in a farther ſupply of new ſhoots, to encreaſe the number of horizontals or bearers; and thus continue encreaſing their number, every year, till the eſpalier is regularly filled from the bottom to top; preſerving all the branches at full length, as far as the allotted ſpace will admit, for the reaſons before explained, both here and under the article Pear, for theſe and the Pear-tree require almoſt exactly the ſame management.

With reſpect to their general culture, they muſt conſtantly have a ſummer and a winter-pruning annually: in the ſummer-pruning to cut out all the ſuperfluous and ill-placed ſhoots of the year, and train regular ones towards the lower parts in vacant ſpaces, if any, at leaſt to remain till winter, ſome of which may be then wanted to fill ſome unforeſeen vacancy, clearing out all others at this time as cloſe as poſſible. And in winter-pruning examine the branches in general, if any worn-out or decayed parts appear, now is the time to retrench them, retaining

young in their place; and if any vacancy occur, retain ſome contiguous young ſhoot to fill it: all others, not now wanted, cut clean out, cloſe to the branches, ſtill continuing all the branches, and any occaſional ſupply of ſhoots, at full length, as far as their limited bounds will allow; then train the whole regularly, tying them in as ſtraight and cloſe to the railing as poſſible, about ſix inches aſunder.

As the Apple and Pear-tree are nearly of the ſame temperature, manner of growth, and mode of bearing, they require nearly the ſame culture; and having treated more fully on the Pears in reſpect to pruning in walls and eſpaliers, which for the general part may be applied to Apples, we refer to that article for more particulars. See PYRUS *Communis*, PRUNING, and ESPALIERS.

In the article Pear-tree, we give ſome hints of another method of training in eſpaliers or for walls, which may alſo be applied to Apples if any one incline to put it in practice for variety.

*Planting them in Standards.*

Standard Apples may be planted both in the garden and orchard: in the garden however they ſhould be arranged but thinly, to admit of undercrops growing freely without interruption of their ſpreading branches.

Obſerve to plant principally full ſtandards for the general ſupply; and half and dwarf ſtandards chiefly for variety, or for ſmall gardens.

The ſtandards having been trained in the nurſery with tolerable good heads, they ſhould now be planted with all their heads entire: if any are intended for the kitchen-garden, plant them at leaſt forty feet diſtance; and for a full plantation to form an orchard, allow thirty feet diſtance every way. Open for each tree a wide hole, trim any broken roots, but leave all the others entire, and plant them with the uſual care, as directed in the article *Planting*; and as ſoon as planted let every one be well ſtaked to ſupport them firmly upright, and prevent their being diſturbed in rooting by tempeſtuous winds. See ORCHARD and PLANTING, &c.

Smaller growing ſtandards ſuch as codlins and dwarfs upon paradiſe ſtocks, may, if required, be planted only at twenty feet diſtance, though if there is room to allow a greater diſtance it will be the greater advantage.

The ſtandards being thus planted with their heads entire. Let them alſo in future advance with all their branches at full length, and for the general part take their own natural growth, and they will ſoon form numerous natural ſpurs in every part for bearing.

With reſpect to pruning theſe ſtandards, very little is required, and that probably not once in ſeveral years, which is only the retrenching any very irregular croſs-placed bough, or reduce to order any very long rambler; or when the head is become greatly crowded and confuſed, to thin out ſome of the moſt irregular growth, likewiſe all ſtrong ſhoots growing upright in the middle of the head, all dead wood, ſuckers from the ſtem and root.

As to half and dwarf ſtandards of theſe trees, they may be diſperſed in different parts of a garden to cauſe variety, managing them as the full ſtandards they will bear plentifully.

Dwarf ſtandards on the dwarf paradiſe ſtock, being very moderate ſhooters, may be planted in a little compaſs; and they are ſometimes planted in pots for curioſity, to place on a table, amidſt a deſert, with the fruit growing. See DWARF TREES.

*Gathering the fruit.*

Apples arrive to full growth in different ſorts ſucceſſively, one after another, from July until the end of October; the ſummer kinds continue but a ſhort time, but the autumn and winter-apples will keep from two or three to ſix or eight months, in different varieties.

The ſummer Apples ripen ſome in July, but principally in Auguſt and September, and are generally fit for uſe immediately from the tree, both for eating and culinary uſes, though ſome of the ſorts are fit for kitchen purpoſes by that time they are half grown, or before, particularly the common Codlin, which boils and bakes in good perfection when quite young, and until full maturity: however, the tokens of perfection, or full growth, of the different ſorts of ſummer Apples, is by their aſſuming a lively colour, emitting a fragrant odour, frequently falling from the tree, and by quitting their hold eaſily on being handled. They ſhould then be gathered and laid in ſome dry apartment for uſe; they will not keep long, nor indeed is it required, for they will

will be ſucceeded by much better in the autumn and winter kinds.

Autumn Apples arrive to maturity in different ſorts, from about the middle of September till the beginning of October: ſome being fit for uſe immediately from the tree, others require to lie a few weeks to mellow, eſpecially for eating: their full growth on the tree is known in ſome by their changing of a more lively colour, ſometimes imparting an agreeable ſmell, frequent dropping, and on being handled, by a gentle twiſt or turn upward, they readily quit the tree; at which which tokens of matureneſs, as they occur in the different ſorts, they ſhould be gathered in dry weather, and carried into the fruitery, where, with proper preſervation, hereafter noticed, they will keep a long time, ſucceeding one another for uſe two or three months, or longer, in the later kinds.

Winter Apples attain full growth about the middle or latter end of October; it is, however, proper to let them hang on the trees till towards the end of that month, or ſome of the lateſt kinds even till November, if the ſeaſon continues mild, but be careful to take them down before attacked by much froſt; gathering them in dry weather, and carry them directly into the fruitery or any dry apartment, and there prepared for keeping as hereafter directed, whereby ſome may be kept ſound and good for uſe till next June or July.

In gathering all the ſorts of Apples for keeping, always chuſe dry weather, and when the trees and fruit are alſo perfectly dry; obſerve likewiſe in gathering Apples for the table, and all kind of Apples, deſigned for keeping any conſiderable time, they ſhould be pulled one and one by hand. Where, indeed, large quantities are deſigned for cyder, or any other immediate uſe, they may be ſhaken down. However, all the fine eating and culinary Apples for keeping ſhould be carefully gathered by hand, by a gentle twiſt or turn upward, ſo as to detach them readily without breaking the fruit-buds; and as they are gathered carry them into the fruitery, &c. where, previous to putting them up for good, it will be proper to lay the choicer varieties of autumn and winter kinds in large heaps, to ſweat and diſcharge the watery juices by perſpiration, which both prepares them for keeping and improves their flavour, then, after having ſweated a week or fortnight, wipe them all perfectly dry, and lay them up where they are to remain. A quantity may be depoſited on the ſhelves and floor of the fruitery, and cloſely covered down a foot thick with ſtraw to exclude the air. And it is proper to pack a quantity of the fineſt winter kinds in large baſkets or hampers, thickly lined round within ſide with ſtraw, covering the fruit down alſo cloſely with the ſame material, to exclude the external air as much as poſſible, whereby they will keep much longer in perfection; and if ſome are packed up in large earthen jars, and cloſely plugged down, they will keep longer ſtill, for it is by theſe methods that the fruit is kept ſo fine and fair even until the return of Apples next year; obſerving, the drier and cloſer the room, in which the fruit is depoſited in all the above methods, the better they will keep; being careful to examine the fruit occaſionally, in order to pick out all that diſcover any tendency to corruption; thoſe in the open fuitery are eaſily looked over, but thoſe in the baſkets and jars not ſo readily, nor indeed will they need it ſo much; however, it is proper, after ſome conſiderable time, to examine them, eſpecially towards ſpring, &c.

In London, great quantities of the fineſt winter Apples are depoſited in the proper ſeaſon in the cloſe warehouſes in Thames-ſtreet, and other parts contiguous to the river, for ſale in winter and ſpring, being packed cloſely in baſkets, &c as aforeſaid, and placed in very cloſe apartments where but little air can come; where they are kept perfectly ſound and beautiful all winter, even until May, June, and July, ſelling them out to the retailers, and we may ſee them in the fruiterers ſhops, and in ſtalls in the ſtreets, exceeding fine in May and June; but after being expoſed to the open air a day or two, they ſhrink, loſe colour, and ſoon decay.

It ſhould therefore be remarked, that cloſe packing theſe fruit, and keeping them in as cloſe apartments as poſſible, keeping the doors and windows, always cloſely ſhut to exclude the external air, is a certain, method of preſerving them long in full perfection, for the more they are expoſed to the air the ſooner they will decay; keep them therefore always as cloſe as poſſible.

*Quince kinds.*

PYRUS *Cydonia*, Quince-tree.

The Quince-tree *(Cydonia)* was long ranged as a diſtinct genus, but is now a ſpecies

of *Pyrus*. It is of the tree kind, of moderate growth, and deciduous; producing large, round, golden-yellow fruit, generally too auſtere and harſh to eat raw, being employed principally for culinary purpoſes.

Claſs, order, and characters the ſame as the Pear, &c. *(Pyrus Communis.)*

There is but one ſpecies, viz.

PYRUS *Cydonia.*

*Cydonia, or Quince-tree.*] Grows ten or twelve feet high, having ſlender branches and ſhoots, forming a low moderately ſpreading head, garniſhed with large, oval, entire leaves, very hoary underneath, and large, ſolitary, whitiſh-red flowers all along the ſides of the branches, ſucceeded by large, round, and pyramidal golden-yellow fruit.

The botanic deſcription is,—*Pyrus* with entire leaves and ſolitary flowers.

*Varieties.*] There are ſeveral varieties of this fruit, but the following are the moſt valuable ſorts.

*Apple-Quince.*—A large, ſhort, roundiſh, apple-ſhaped, golden-yellow Quince.

*Pear-Quince.* — A large, pyramidal, or pear-ſhaped, deep-yellow Quince.

*Portugal Broad-leaved Quince.*—The tree is of larger growth and with broader leaves: pear-ſhaped fruit, having a tenderiſh pulp, which bakes and boils to a fine purple colour.

*Eatable Quince.* — A middle-ſize downy Quince, having a tender pulp, and is ſometimes eaten raw, though for the moſt part rather diſagreeable to moſt palates.

Moſt of theſe fruit though remarkably beautiful to the eye, are too harſh and unpalatable to eat raw; their chief uſes being for baking and ſtewing, to make marmalade, and to mix in apple pies, tarts, &c. to improve the flavour.

The trees, however, merit culture in every curious collection, ſome for the fruit, and others for ornament; but conſidered as fruit-trees, a few is ſufficient to produce fruit enough to ſupply a large family, and may be trained both in ſtandards and eſpaliers to effect the greater diverſity; and as ornamental trees, they are eligible furniture for the ſhrubbery, &c. their numerous large flowers and golden fruit will effect a delightful variety; the flowers in ſpring and the fruit in autumn. Young Quince-trees are alſo in repute for ſtocks, on which to graft and bud Pears, to dwarf them for walls and eſpaliers. See PYRUS *Communis* and STOCKS.

They are very hardy, and will grow any where, but delight moſt in ſomewhat moiſt ſituations, and are therefore often planted by the ſides of ponds or ditches of water.

*Method of Propagation, and general Culture.*

The trees may be raiſed from the kernels of the fruit ſowed in autumn, but there is no depending on having the ſame or any good fruit from ſeedlings.

But the ſeveral varieties may be continued always the ſame by the propagation, by cuttings and layers; alſo by ſuckers from ſuch trees as grow upon their own roots, and may likewiſe be propagated by grafting and budding upon their own or Pear-ſtocks raiſed from the kernels.

The propagation by cuttings, layers, and ſuckers, may be performed in autumn, winter, or ſpring. Chuſe young wood for the cuttings and layers, which plant and lay in the common method, and they will be rooted by next autumn, then tranſplanted into nurſery rows two feet aſunder; plant the ſuckers alſo at the ſame diſtance, and here train the whole for the purpoſes intended: if for ſtandards, run them up with a ſtem, to any deſired height, from three to ſix feet, then encourage them to branch out at top, to form a head; and thoſe deſigned as dwarfs muſt be headed near the ground, and trained accordingly for eſpaliers, or dwarf ſtandards, as may be required, as directed under thoſe articles.

When they have formed tolerable heads plant them out finally.

Standard Quinces, deſigned as fruit-trees, may be ſtationed in the garden or orchard, and ſome by the ſides of any water in bye places, ſuffering the whole to take their own natural growth.

And as eſpaliers, they may be arranged in aſſemblage with other moderate-growing trees, ſuch as Apples and Pears on Paradiſe and Quince ſtocks, Cherries, &c. and train them as directed for Apples and Pears in eſpaliers.

In ſhrubberies they may be planted either as full or low ſtandards, and permit them to take their own way of growth.

# Q.

QUERCUS, Oak-tree.

This famous genus compriſes a noble collection of moſt eminent foreſt and ornamental trees, both deciduous and evergreen kinds obtaining in ſtature from twenty to near a hundred feet, in different ſpecies, garniſhed with oblong and moſtly ſinuated leaves, and monoecious apetalous flowers, of but little appearance, ſuceeded by oval nuts, called acorns.

Claſs and order. *Monoecia Polyandria.*

*Characters.*] CALIX, male and female, flowers ſeparate on the ſame plant; the males diſpoſed in loſe amentums, each floret having a monophyllous four or five-parted calix; and the females ſitting cloſe to the buds, have monophyllous, hemiſpherical, coriaceous, rough, entire cups.—COROLLA, no petals.—STAMINA, many ſhort filaments in the males, having didymous antheræ.—PISTILLUM, a ſmall oval germen in the females, quinquefid ſtiles, and ſimple permanent ſtigmas.—PERICARPIUM, none; the ſeed, an oval nut or acrorn, with a leathery univalvular ſhell, is fixed by its baſe into the calix.

There are about fourteen ſpecies, nine deciduous, and five evergreen kinds; but the *Common Engliſh Oak* is the glory of the collection, for its ſuperior growth, and great worth and value, as a timber-tree, for bulk, ſtrength, and duration. Several of other ſpecies have alſo their ſhare of merit, ſome as foreſt-trees, others to adorn ornamental plantations.

*Deciduous kinds.*

Under this head, Deciduous Oaks is compriſed, the common Oak of our woods and foreſts, and ſeveral ſpecies of North America, and ſome foreign parts of Europe, as France, Spain, Portugal, and Italy, as expreſſed in their titles; all of which are of the tree kind, deciduous and of hardy growth.

[1]QUERCUS *Robur.*

*Robur, or Common Engliſh Oak.*] Grows from about 60 or 70 to 100 feet high, with a prodigious large trunk, and monſtrous ſpreading head, oblong leaves, broadeſt towards the top, the edges acutely ſinuated, having the angles obtuſe.

*Varieties.*] Striped-leaved Oak, having the leaves finely ſtriped with white.

This ſpecies grows in great abundance all over England in woods, foreſts, and hedge-rows; is naturally of an amazing large growth, there being accounts of ſome above an hundred feet ſtature, with wonderful large trunks and ſpreading heads, and is ſuppoſed will continue its growth many centuries.

[2]QUERCUS *Prinus.*

*Prinus, or Cheſnut-leaved American Oak.*] Grows fifty or ſixty feet high; having large, oblong-oval, ſmooth leaves, pointed both ways, the edges ſinuated-ſerrated with the ſinuſes uniformly round.

[3]QUERCUS *Phellos,*

*Phellos, or Willow-leaved American Oak.*] Grows forty or fifty feet high, having long, narrow, ſmooth, entire leaves like thoſe of willow.

*Variety.*] Dwarf Willow-leaved Oak.

[4]QUERCUS *Alba.*

*White Virginian Oak.*] Grows thirty or forty feet high, having a whitiſh bark, long, obliquely-pinnatifid, light-green leaves, the ſinuſes and angles obtuſe.

[5]QUERCUS *Nigra.*

*Black Virginian Oak.*] Grows thirty or forty feet high, having a dark-coloured bark, large, wedge-ſhaped, ſlightly-trilobated leaves.

[6]QUERCUS *Rubra.*

*Red Virginian Oak.*] Grows about ſixty feet high, having a dark-greyiſh bark, long obtuſely-ſinuated leaves, with the ſinuſes terminated by briſtly points, and have ſometimes red-ſpotted veins, but generally dying in autumn to a reddiſh colour, remaining on the trees late in the ſeaſon.

[7]QUERCUS *Eſculus.*

*Eſculus of Pliny, or Cut-leaved Italian Oak.*] Grows about thirty feet high, having a purpliſh bark, oblong, deeply-ſinuated, ſmooth leaves, and

and long, ſlender, cloſe-ſitting acorns in very large cups.

[8]QUERCUS *Ægilops.*

*Ægilops, or Large Prickly-cupped Spaniſh Oak.*] Grows ſeventy or eighty feet high, or more, with a very large trunk, and widely-ſpreading head, having a whitiſh bark, large, oblong-oval, deeply-ſerrated, ſmooth leaves, the ſerratures repand or bowed backward, and large acorns placed in ſingularly large prickly cups.

This is a noble ſpecies, almoſt equal in growth to our common Engliſh Oak.

[9]QUERCUS *Cerris.*

*Cerris, or Smaller Prickly-cupped Spaniſh Oak.*] Grows thirty or forty feet high, oblong, lyre-ſhaped, pinnatifid, tranſverſly-jagged leaves, downy underneath, and ſmaller acorns, placed in prickly cups.

All the above ſpecies of deciduous Oak, may be cultivated both as foreſt-trees and in diverſifying large ornamental plantations; as timber or foreſt-trees, however, is their principal merit, but the Engliſh Oak claims the preference for general uſe, as the moſt valuable for timber, and ſhould raiſe a greater quantity of it accordingly.

They are all eaſily raiſed from ſeed, i. e. the acorns, ſowed in the autumn an inch deep. See their *Propagation.*

*Evergreen kinds.*

Of evergreen Oaks there are five ſpecies.—Common evergreen Oak. — Holly-leaved Oak.—Cork-tree.—Scarlet Oak,—and Moluccan or Live Oak; ſome as timber-trees, others for ornament, all of which retain their leaves the year round; are originally of foreign growth, moſtly from the ſouthern parts of Europe, and one from America, but have been long in the Engliſh gardens as ornamental trees, and ſome are arrived to a conſiderable growth, they being all very hardy, and proſper in any open ground.

[10]QUERCUS *Ilex.*

*Ilex, or Common Evergreen Oak.*] Grows forty or fifty feet high, having a ſmooth bark, oval and oblong, undivided, ſerrated, petiolated leaves, downy and whitiſh underneath.

*Varieties.*] Broad-leaved.—Narrow-leaved, and with ſometimes both ſorts, and other different ſhaped leaves on the ſame tree; alſo ſometimes with ſawed and prickly leaves.

[11]QUERCUS *Gramuntia.*

*Montpelier Holly-leaved evergreen Oak.*] Grows forty or fifty feet high; oblong-oval, cloſe-ſitting, ſinuated, ſpinous leaves, downy underneath, bearing a reſemblance to the leaves of holly.

[12]QUERCUS *Suber.*

*Suber, or Cork-tree.*] Grows thirty or forty feet high, having a thick, rough, ſungous, cleft bark, oblong-oval, undivided, ſerrated leaves, downy underneath.

This ſpecies furniſhes that uſeful material Cork; it being the bark of the tree, which becoming of a thick ſungous nature, under which, at the ſame time, is formed a new bark, and the old being detached for uſe, the tree ſtill lives, and the ſucceeding young bark becomes alſo of the ſame thick ſpongy nature in ſix or ſeven years, fit for barking, having likewiſe another freſh bark forming under it, becoming Cork, like the others, in the like period of time; and in this manner theſe trees wonderfully furniſh the Cork for our uſe, and of which is made the corks for bottles, bungs for barrels, and numerous other uſeful articles.

The tree grows in great plenty in Spain and Portugal, and from which countries we receive the Cork.

[13]QUERCUS *Coccifera.*

*Scarlet, or Kermes Oak.*] Grows but fourteen or fifteen feet high, branching all the way, and of buſhy growth; large, oval, undivided, indented-ſpinous leaves; and producing ſmall glandular excreſcencies, called kermes or ſcarlet grain, uſed by the dyers.

The ſmall ſcarlet glands, found on this tree, is the effect of certain inſects depoſiting their eggs betwixt the bark of the branches and leaves, cauſes an extravaſation of the ſap, and forms the excreſcence or ſubſtance in queſtion, which being dried, is the kermes or ſcarlet paſtel.

[14]QUERCUS *Molucca.*

*Moluccan Oak, commonly called American Live Oak.*] Grows about forty feet high, having oval, ſpear-ſhaped, ſmooth, entire leaves, and ſmall, oblong, eatable acorns.

All the above fourteen ſpecies of *Quercus* produce flowers annually in the ſpring, about April and May, of a yellowiſh colour, but make no ornamental appearance, and are males and females ſeparated in the ſame tree; the males being in looſe amentums, and the females ſitting cloſe to the buds in thick leathery hemiſpherical calixes, ſucceeded by the fruit or acorns, which are oval nuts fixed by their baſe into rough permanent cups, and moſtly ſit quite cloſe, and ſome on ſhort

foot-

ſoot-ſtalks, ripening in autumn, which in the common Engliſh Oak is in great abundance, and often in tolerable plenty on ſome of the other ſorts; thoſe of all the kinds ſerve for propagating their reſpective ſpecies; they are alſo excellent food for ſwine and deer, the common Oak in particular.

Oak-trees, of all the above ſorts, may be employed in gardening to diverſify large ornamental plantations in out-grounds, and in forming clumps in ſpacious lawns, parks, and other extenſive opens; the evergreen kinds in particular have great merit for all ornamental purpoſes in gardens.

But all the larger growing kinds, both deciduous and evergreens, demand eſteem alſo as firſt-rate foreſt-trees for their timber: the *Engliſh Oak*, however, claims precedence as a timber-tree, for its prodigious height and bulk, and ſuperior worth of its wood, and is ſuppoſed will ſtand one thouſand years before it totally decays, ſo is ſingularly valuable for all ſtrong and durable purpoſes, ſuch as ſhip-building, ſome parts of houſe-building, park-paling, poſts, railing, and innumerable other uſes. But all the other large-growing Oaks may likewiſe be introduced in foreſt-tree plantations, for Oaks in general prove valuable timber, and of all others the moſt durable; and beſides their value as timber-trees, their annual crops of acorns prove moſt excellent food for fattening hogs and deer; and when the trees are felled for uſe, their bark, being ſtripped off, proves a moſt valuable material to the tanners for tanning leather; and after having ſerved that purpoſe, is of great uſe in gardening for making bark hot-beds, commonly called bark-beds, being the moſt eligible kind of hot-beds for the culture of the pine-apple, and all other tender exotics of the hot-houſe temperature. Oaks, therefore, being of ſuch ſuperior value, every poſſeſſor of conſiderable eſtates ought to be particularly aſſiduous in raiſing woods of them, which is effected by ſowing the acorns either in a nurſery, and the plants tranſplanted where they are to remain, or ſowed at once in the places where they are always to ſtand. See their *Propagation*, PLANTATIONS, and FOREST TREES.

All the ſorts will proſper in any middling ſoil and open ſituation, though in a loamy ſoil they are generally more remarkably proſperous; however, there are but few ſoils in which Oaks will not grow; they will even thrive tolerably in gravelly, ſandy, and clayey land, as may be obſerved in many parts of this country of the common Oak.

*Their Propagation and general Culture.*

Oaks in general are raiſed from the acorns, which, of the common Oak, are produced abundantly all over England, and ſhould be gathered in autumn when quite ripe, juſt as they drop from the trees; but the acorns of moſt of the foreign oaks are generally procured from abroad; and thoſe of all the ſpecies are ſold by the ſeedſmen.

Obſerve to ſow all the ſorts as ſoon after they are obtained as poſſible, becauſe they are apt to ſprout if they remain long out of the ground. Prepare for their reception a ſpot of light ground in the nurſery, dividing it into four-feet wide beds, and in which ſow the acorns, either in drills two inches deep, in five or ſix rows, lengthwiſe the bed, or rake the mold off the bed, the depth of two inches, into the alleys, then ſow the acorns all over the ſurface, about two or three inches apart, preſs them down with the ſpade, and ſpread the earth evenly over them two inches thick.

They will come up in the ſpring; give them occaſional waterings and weedings, and when the plants are one or two years old, it is proper to plant them out in nurſery-rows: this may be done in autumn, winter, and early in the ſpring, taking them carefully up out of the ſeed-bed: ſhorten their tap-root, and trim off any lateral ſhoots from the ſtem, leaving their top perfectly entire, then plant them in lines two feet and half aſunder, and fifteen or eighteen inches in the rows, where let them ſtand, with the uſual nurſery care, till of a proper ſize for final tranſplantation, either as foreſt trees, or ſome for ornament, training them up as full ſtandards, with clean ſtraight ſtems and with their tops ſtill entire.

Remark, the propagation of the ſtriped-leaved varieties of the common Oak, and any particular variety of the other ſpecies, muſt be effected by grafting, as they will not continue the ſame from ſeed, ſo the grafting may be performed upon any kind of Oakling-ſtocks raiſed from the acorns, and train them for ſtandards like the others.

*Tranſplanting them finally.*

When the trees of all the ſorts are from about three or four to ſix feet ſtature, they ſhould be planted out for good, though, conſidered

ſidered as foreſt or timber-trees in particular, it is more eligible to plant them out finally whilſt they are quite young, not advanced above from two to three or four feet in height; or if planted immediately from the ſeed-bed, where they are finally to remain, it may prove a greater advantage, as the quite young Oaks root more freely than older trees, and take a freer growth.

However, in this final tranſplantation, obſerve to plant thoſe deſigned as foreſt or timber-trees, in large open tracts of grounds to form woods, placing them in rows only four feet aſunder, and one or two feet in the rows, to allow for a gradual thinning. See PLANTATIONS and PLANTING.

Sometimes, however, large plantations of theſe trees, for woods, are raiſed by ſowing the acorns at once in the places where they are to remain, as formerly noticed, it being the opinion of many, that the trees, raiſed at once from the acorn, receiving no check by removal, much outſtrip the tranſplanted trees in growth. The method is this; the ground being prepared by good ploughing and harrowing, then, in autumn, having procured a proper quantity of acorns, draw drills acroſs the ground four feet aſunder, and two inches deep, drop the acorns therein ſix or eight inches aſunder, allowing for ſome failing and for thinning hereafter, covering them in evenly with the earth the depth of the drills, or inſtead of drilling them in they may be planted with a dibble the ſame depth and diſtance.

As to the general management of theſe trees in woods or timber plantations, it is the ſame as directed for foreſt trees in general, under the article PLANTATION, which ſee.

In planting any or all the ſpecies of Oak, for ornament or variety in large pleaſure-grounds, ſome may be diſpoſed in aſſemblage in any continued plantation, ſome in clumps, and others as ſingle objects.

QUINCUNX Planting.

The Quincunx order of planting ſignifies trees planted by fives, four of them forming a ſquare, and the fifth placed in the middle, thus ⁘ and may be repeated over and over in one continued plantation, with as many trees in ſeveral ranges as thought proper, and was formerly a faſhionable mode of planting groves and other regular plantations in the following arrangement.

. . . . . .
. . . . . .
. . . . . .

Somewhat of this mode of arrangement ſhould generally be obſerved in the diſpoſition of ſhrubbery plants, &c. though not in a regular Quincunx, but ſomething nearly in this order, which both gives the ſhrubs a greater ſcope of growth, and they ſhew themſelves to greater advantage.

This mode of planting is alſo proper in the kitchen-garden, in tranſplanting many kind of eſculent plants, ſuch as lettuce, endive, ſtrawberries, and even all the cabbage kinds, and many other plants which gives them a greater ſcope to grow than if planted exactly ſquare at the ſame diſtance.

---

# R.

RACEMUS, a Cluſter, or mode of cluſter-flowering, being a long cloſe Cluſter of flowers or fruit, conſiſting of one common peduncle or foot-ſtalk, branching and ſupporting many ſhort lateral ones all along its ſides, theſe immediately ſuſtaining the flowers and fruit: examples of a *Racemus* are bunches of grapes and currants, See VITIS and RIBES.

RACER, or Rutter. A cutting implement uſed in racing or marking out the proper width, length, and thickneſs of graſs turfs for gardens, previous to fleaing or cutting them up for laying.

It

It is a ſimple but uſeful tool for the above purpoſe; conſiſting of a ſtrong wooden handle about four feet long, having the point-end of an old ſcythe for a cutter, fixed at the lower end, with the point and edge downward, to cut into the ſward; the handle ſhould be about an inch and half thick, growing gradually thicker towards the lower end, and ſomewhat bending or ſloping at the bottom to reſt on the ground, having at the bottom part a ſlit longitudinally, to receive the cutter, which ſhould be five or ſix inches long, placing it with the point and edge downward, as aforeſaid, projecting an inch and half out at the back of the bottom of the handle in a ſlanting manner with the point inwards, fixing it firmly in that poſition, ſo as when puſhed before you it may expeditiouſly cut the ſward as you race it along.

Having this inſtrument, then mark out on the ſward the width of the turf intended to be cut, which ſhould be generally a foot wide and a yard long, and ſtraining a line tight, ſtrike the racer into the ſward cloſe to the line, run it along, it will expeditiouſly cut its way and divide the ſward to a proper depth; directly place the line a foot farther, and race it out as before, and ſo on to as many widths as may be wanted; then race it croſs ways in yard lengths: being thus raced out, the turf cutter with his turfing-iron proceeds to cut them up, and he will flay them off at a great pace in exact widths and lengths as above.

RADIATUS *flos*, a radiated flower.—Such compound flowers as are furniſhed with a radius or ſpreading circumference. See RADIUS.

RADIUS, the Radius, or circumference, or outer ſpreading part of compound flowers, conſiſting of many flat florets ſet round the diſc or middle, and ſpread out all around, reſembling the figure of a radiant ſtar, exemplified in *aſter* or ſtar-wort, marigold, ſunflower, and many others of the compound tribe, and of which there are both ſingle and double flowers; the ſingles having only one ſeries of florets in the radius, but the doubles have from two or three to many ſeries, continued ſometimes to the very center. See COMPOSITUS *flos*.

RADICULA (from *Radix*) Radicle or Little Root, or ſmall fibrous part iſſuing firſt either immediately from the ſeed, or that which terminates the ſtock or main root, penetrates into the ſoil and draws nouriſhment for the production and ſupport of the plant, and is the principal and eſſential part of every root of all vegetables.

RADIX, the Root, or lowermoſt part of a vegetable ſituated, within the ground, deſtined to draw nouriſhment from the ſoil for the production and ſupport of all the other parts of the plant.

A Root conſiſts of two parts, viz. 1. The ſtock or main Root (*Caudex*) that ſtrikes downward into the earth, and puts forth radicles or fibres. 2. The radicle (*Radicula*) ſmall thread-like roots or fibrous parts, terminating the ſtock or main Root, or proceeding from any part thereof, and is the principal or eſſential part of every Root, as it penetrates far into the ſoil and attracts nouriſhment to the main ſtock, thence communicated to the ſtem, branches, and other parts of the vegetable.

From the various ſtructures and directions of the ſtock or main Root the botaniſts diſtinguiſh them by the following terms.

*Perpendicular Root.*] Deſcends in a ſtrait line downwards. *Radix perpendicularis.*

*Horizontal Root.*] Runs in a horizontal or tranſverſe direction along under the ſurface of the earth. *Radix horizontalis.*

*Simple Root.*] Such that is ſingle and not ſubdivided.

*Branched Root.*] Divided into lateral branches, which alſo ſubdivide into ramifications. *Radix ramoſa.*

*Spindle-ſhaped, or tapering Root.*] Is oblong, thick upwards, and tapers gradually to the lower extremity, ſuch as common radiſh, carrot, parſnep, &c. *Radix fuſiformis.*

*Bulbous Root.*] Roundiſh and oval ſwelling bulb, compoſed ſome of many ſucculent imbricated ſcales, others of many involving coats, and conſiſt of two ſorts: 1. Scaly bulbs, (*Bulbus Squamoſa*) formed of many ſcales lying over one another, as in the lily. 2. Tunicated or coated bulbs (*Bulbus tunicatus*) formed of ſeveral tunics or coats cloſely involving one another, as in the tulip and onion, &c. *Radix Bulboſa.*

*Tuberous Root.*] A thick fleſhy knob, formed of a ſolid lump, ſome roundiſh, others irregularly knobbed, and ſome oblong, compoſed either of one ſingle knob, or ſeveral collected into bundles; examples of the tuberous rooted tribe are the potatoe, Jeruſalem artichoke, anemone, pœony, orchis, filipendula, and hemerocallis; the turnep,

carrot, and parſnep, may alſo be conſidered of the ſame kind, and all other Roots that are formed of a thick, fleſhy, ſolid ſubſtance. *Radix tuberoſa.*

*Fibrous Root.*] Compoſed wholly of a number of radicles, or ſlender fibrous parts, and may be ſaid to be the moſt common ſort of Root, to numerous herbaceous plants in particular, and conſiſts of perpendicular Roots, horizontal Roots, ſimple Roots, branched Roots; ſome being very thin and fine like threads, others ſomewhat fleſhy, &c. *Radix fibroſa.*

*Creeping Root.*] Runs along juſt under the ſurface of the earth to a conſiderable length, emitting at certain diſtances ſmall fibres below and ſhoots at top. *Radix repens.*

*Globular Root.*] Roundiſh, fleſhy, ſolid Root of the tuberous kind, ſuch as earth-nut, bulbous fumatory, &c. *Radix globoſa.*

*A grumous or bundled Root* ] Compoſed of many ſmall, oblong, fleſhy, kernelly parts, or knobs, all connected at top, and terminated below in radicles or fibres, ſuch as *Ranunculus*, &c. *Radix faſciculata.*

*Granulous aggregate Root.*] Conſiſts of many ſmall roundiſh knobs like grains of corn all, cluſtered together, as in white ſaxafrage. *Radix granuloſa.*

*Pendulous cluſtered Root.*] Compoſed of ſeveral fleſhy, roundiſh, knobs, or tubers, ſuſpended, as it were, at the ends of fibres, as in filipendula, pœony. potatoe, Jeruſalem artichoke, aſphodelus, hemerocallis, &c. all of which being of the tuberous-rooted kind. *Radix pendula.*

*Handed tuberous Root.*] An oblong tuberous Root, dividing and ſpreading like an open hand, as in handed-orchis. *Radax tuberoſa palmata.*

*Teſticulated Root.*] Compoſed of two roundiſh tuberous knobs joined in a teſticulated manner, as in ſome ſorts of orchis. *Radix teſticulata.*

*Jointed Root.*] Long, thickiſh, and jointed at certain diſtances. *Radix articulatus.*

*Woody Root.*] Becoming of a hard, tough, woody texture, ſuch as the Roots of all trees, ſhrubs, and under-ſhrubby plants. *Radix lignoſus.*

*Tap Root.*] Any main Root that runs ſtrait downward in a perpendicular direction, like a carrot, parſnep, &c. and is often applicable to the tree and ſhrub kind, when the main Root runs directly downright; and in tranſplanting ſeedling-trees in the nurſery, &c. it is occaſionally recommended to ſhorten the Tap-Root, with a deſign both to prevent their penetrating too deep into the bad ſoil, and ſo force out horizontal or lateral roots, to extend horizontally nearer the ſurface into the good earth, where they may draw better nouriſhment. See PLANTING.

As to the duration of Roots, they are either annual, biennial, or perennial, viz.

*Annual* ROOTS.——Such that endure but one year at moſt, then totally periſh; as of all thoſe vegetables denominated annual plants. *Radix annuus.*

*Biennial* ROOTS.—— Continue but two years, then wholly decay. *Radix biennis.*

*Perennial* ROOTS ——Being of many years duration, and in ſome plants both Root and ſtem ſubſiſt for many years, particularly all the tree and ſhrub kind: many herbaceous vegetables likewiſe enjoy the ſame privilege, though the greater part are only perennial in Root, renewing the ſtalks, &c. annually: however, all herbaceous plants having durable or perennial Roots, are from this circumſtance denominated perennials. *Radix perennis.*

Roots, we obſerved for the general part, penetrate within the ground to ſeek nouriſhment from the ſoil; there are however ſome exceptions; the miſletoe plant attaching itſelf to the branches of trees, with its Root uppermoſt, which penetrates into the bark and wood, drawing moiſture for its ſuſtenance. Moſſes and ſome of the fungi likewiſe attach their Roots to the bark of trees; lichens to ſtones and rocks, and ſome aquatics ſwim both Root and top on the ſurface of the water.

RAKE, a Garden-Rake for raking ground and raking in ſeeds, &c.

To ſuit every department of gardening completely with Rakes, there ſhould be three or four different ſizes from about ſix to eighteen inches long in the head, having handles from ſix to eight or nine feet in length, and the head teethed with iron teeth two or three inches long, and placed from one to two inches aſunder, according to the reſpective ſizes of the Rakes for particular uſes, as below.

*A large* RAKE.—Having the head about twenty inches long, the teeth three inches and half, and placed two inches aſunder; being proper for raking ſtubborn or rough dug ground, and for raking in large kinds of ſeeds, raking off large weeds after hoeing, and

and for many other purpoſes in large gardens.

*A middle-ſized* RAKE—Having the head ſixteen inches long, the teeth three inches, and placed one inch and half aſunder; being proper for all common raking in ordinary light ground, and for raking in moſt kinds of ſmall ſeeds, and many other purpoſes.

*A ſmall* RAKE.—Having the head twelve inches long, the teeth two and a half, and placed one inch aſunder; proper for fine-raking beds, borders, &c. and raking between certain plants occaſionally, where larger rakes cannot be introduced.

*A little* RAKE. —Having the head eight inches long, the teeth two and a half, and placed one aſunder; being very uſeful for raking between ſmall plants in beds and borders and other ſmall compartments where the plants ſtand cloſe.

Garden Rakes are made commonly with wooden heads and iron teeth, and have a ſtrait pole for a handle an inch and half thick, and from about ſix to eight or nine feet long, as aforeſaid, having each end of the head hooped with an iron ring to ſecure it from ſplitting; and the teeth being generally made flat, the back-edge rounded off to a point, the other ſtraight, and are placed edgeways with the points all inclining moderately inward. But ſome Garden Rakes have both head and teeth wholly of iron, which, if made neat and light, the teeth well ſet and firmly faſtened, they prove tolerable handy and durable; but as the teeth are rarely ſet with a proper come, as in the wooden-headed rakes, and being very liable to get looſe, I ſhould therefore rather prefer the wooden-headed ones for general ſervice.

Entire wooden Rakes, having the head, teeth, and handle, wholly of wood, are ſometimes uſed for particular purpoſes, ſuch as raking in ſome light kinds of kitchen-garden ſeeds in very light ground, and for raking off large hoed-up weeds in vacant or wide clear ſpaces, raking up ſwarths of mowed ſhort graſs before the ſweepers, alſo fallen leaves of trees in autumn, and clippings of hedges, &c. and for ſeveral other uſes.

RAKING. Raking ground is a neceſſary culture in many caſes, to break the ſurface of the ſoil ſmall, and render it fine for the reception of particular ſorts of ſmall ſeeds and plants previous to ſowing and planting.

Likewiſe after ſowing ſeeds in the broad-caſt way on rough ground, we rake them in to bury them a proper depth for germinating: Raking in ſeeds is the moſt expeditious mode of covering them in garden-ſowing all kinds of ſmall ſeeds of hardy plants; the ground being dug, &c. and the ſurface remaining rough after the ſpade, the ſeed is then ſowed, and then raked in with an even hand, raking only once or twice in a place, a back and a fore ſtroke, which being generally ſufficient to cover moſt ſorts of ſeeds effectually; and is the moſt elegible and expeditious method in the ſowing moſt kinds of eſculent or kitchen-garden ſeeds, and of moſt kinds of hardy flower ſeeds, and ſome ſorts of ſmall tree and ſhrub ſeeds. See SOWING SEEDS.

Raking the ground alſo among growing plants that ſtand diſtant enough to admit the rake, is in many caſes of ſervice, particularly where the ſurface is inclinable to bind, or where numerous ſmall ſeed-weeds appear, it will looſen the ſoil and retard the growth of the weeds.

And Raking ground is in many caſes neceſſary for ornament, ſuch as raking ſmooth the beds, borders, and other compartments of pleaſure-grounds, which being now and then repeated gives an air of culture and neatneſs to the premiſes.

Likewiſe after hoeing up weeds Raking them off is eligible in all conſpicuous parts of the pleaſure ground, in particular where neatneſs is required, alſo in other diſtricts where the weeds are like to grow up again or ſhed their ſeeds as they lie on the ground.

All Raking ſhould generally be performed in dry weather and when the ground is alſo moderately dry, for if raked in rainy weather, or when the ground is very moiſt and cloggy, the ſurface is apt to cake and bind hard; this ſhould be particularly attended to in ſowing ſeeds, nor will rough digged ground rake well when it is become very dry at top, eſpecially if it was digged wet and ſuffered to lie till the clods have become dry and hard, in which caſe it will not rake well until mellowed or pulveriſed by a ſhower of rain.

But moſt of our common light garden-ground generally rakes beſt when freſh digged, perhaps the ſame day, or day after at fartheſt, before dried too much by the ſun and wind, or rendered wet by rain, &c.

However Raking ſhould be performed when the ground is in ſuch order as the clods will readily break and fall to bits under the rake without clogging much thereto.

With reſpect however to Raking ground ſowed with ſeed, particularly in ſpring and ſummer it is of importance to ſow the ſeed generally when the ground is freſh turned up, provided it will readily rake without clogging as aboveſaid.

RANUNCULUS, Ranunculus and Crowfoot.

This genus compriſes a large collection of hardy herbaceous perennials of the grumous and fibrous rooted tribe; ſome of them moſt beautiful flowery plants of the gardens, others common weeds of the fields and meadows; the garden kinds having great merit as flower-plants for adorning the flower-garden and pleaſure-ground, garniſhed with divided and entire leaves in different ſpecies, and moſtly upright branchy flower-ſtalks, from half a foot to two feet high, terminated by pentapetalous and polyandrous flowers, having double varieties of exceeding beauty.

Claſs and order, *Polyandria, Polygynia.*

*Characters.*] CALIX, five oval concave coloured leaves.——COROLLA, five obtuſe petals, having ſmall ungues, and a nectarium formed of a ſmall open cavity near the baſe of each petal.——STAMINA, numerous filaments half the length of the petals, having oblong erect didymous antheræ.—PISTILLUM, numerous germina collected into a head, no ſtyles, but very ſmall reflexed ſtigmas.—PERICARPIUM, none, numerous irregular ſeeds attached to the common receptacle by very ſhort pedicles.

There are near forty different ſpecies of this genus, ſix or eight of which claim general eſteem as flowery plants for ornamenting the gardens, and a great number are common weeds in the fields, waters, and paſture ground, not having merit for garden culture: of the garden kinds, the principal ſort is the *Aſiatic or Turkey and Perſian Ranunculus*, which compriſe many hundred varieties of large, double, moſt beautiful flowers of various colours; but ſeveral other ſpecies having varieties with fine double flowers, make a good appearance in a collection, though as thoſe of each ſpecies conſiſt only of one colour, ſome white others yellow, they are inferior to the *Aſiatic Ranunculus*, which being large and diverſified a thouſand ways in rich colours, in different varieties; however, all the garden-kinds in general, deſcribed below, effect a very agreeable diverſity in aſſemblage in the flower compartments, &c. and they being all very hardy ſucceed in any open beds and borders, &c.

The moſt noted kinds for garden culture are the following eight ſpecies.

RANUNCULUS *Aſiaticus.*

*Aſiatic, or Turkey and Perſian Ranunculus.*] Hath a ſmall grumous or bundled root, compoſed of many ſmall knobbed parts connected at top; crowned with ternate and double-ternate leaves, having trifid-cut lobes; upright flower-ſtalks branching below, and riſing from ſix to ten or twelve inches high, terminated each by one large flower of many different colours and properties in the varieties; flowering in April, May, and June.

Is a native of Aſia, and introduced here long ſince from Turkey and Perſia, and by way of diſtinction is moſt commonly called ſimply *Ranunculus.*

*Varieties.*] The varieties of this ſpecies are amazingly numerous and are divided into two claſſes, the Old Turkey kind and the Perſian kinds, the varieties of the latter amounting to many hundreds and are conſiderably more various, rich, and beautiful in colour than the others.

*Old Turkey kinds.*] Riſe with a ſtrong generally unbranching ſtalk a foot high, terminated by one large double flower, ſometimes emitting one or two ſmaller ones from its ſides, and of which there are Red flowered,—Scarlet flowered,—yellow flowered—and Scarlet turban flowered, &c.—they being ſeldom tinged with different colours like the Perſian kinds.

*Perſian varieties.*] Riſe eight or nine inches high, generally branching from the bottom, producing from five or ten to twenty or thirty flowers on each root, and of which there are Single flowered——Semi-double flowered,——Full-double flowered, being large and full like a double roſe, generally filled with petals to the very centre, forming a regular, globular body of admirable elegance, of all ſorts of the moſt beautiful colours in different varieties, and of numerous degrees of deeper and lighter ſhades, ſtripes, and tinges in the ſeveral colours, ſo as to cauſe an aſtoniſhing diverſity of Reds,—Scarlets,—Crimſons,—Fleſh-colours—Purples—Blues,—Violet colours,—Whites,—Cream-colours,—Aſh-colours,—Yellows,—Orange-colours,—Lemon-colours,—Golden-yellow,

yellow,—Olive-yellows,—Browns,—Copper-colours,—Blacks,—Black-purples,——Black-violets,—Tawney-colour,—Coffee-colour, &c.—and with flowers of all the above colours variouſly tinged and ſtriped with two, three, or more different colours, in a very curious manner, forming the numerous varieties, amounting to above a thouſand, deſcribed in ſome of the eminent flower-dealers catalogues, varying from one another in ſome particular in different colours, tints, ſtripes, and variegations; and a farther encreaſe of new varieties are annually obtained from ſeeds, the ſeedlings generally flower the ſecond or third year, and the ſelect kinds are continued and encreaſed plentifully by offſets from the root, every ſummer after they have done flowering.

All the varieties flower commonly in April and May, but by late planting the roots the blow may be continued till June; and the ſingle and half double flowers are ſucceeded by abundance of ſeed, but rarely any from the full doubles: the ſemi-doubles, however, are greatly preferable to the ſingles, from which to ſave the ſeed for ſowing, as there will be a greater chance of having double flowers and ſeedlings in return.

The roots of all the varieties of this ſpecies are of the keeping kind, and being lifted in ſummer ſoon after flowering, the off-ſets ſeparated and properly dried, they may be kept out of the ground ſeveral months; but it is proper to plant a quantity in autumn, and the reſt in ſpring, in order to procure a longer ſucceſſion of the flowers.

Theſe roots are ſold by all the nurſerymen and ſeedſmen in great variety, at from two or three ſhillings to four or five pounds per hundred and ſometimes conſiderably more, for ſome very curious varieties.

They are all hardy enough to ſucceed in any common light garden-earth in open beds or borders, planted ſome in autumn about September, October, or November, but principally the two latter months, and the reſt in February; the fine ſorts being commonly depoſited in beds by themſelves in rows ſix or eight inches aſunder and two or three deep; both to exhibit a grand ſhew of the numerous varieties all together, and for the convenience of giving occaſional ſhelter from cutting froſts; the early autumnal plantings in particular, that appear above ground in winter or early in ſpring: though the latter autumnal plantings put in about November, as they will not come up ſo early, do not require ſo much care, and the ſpring plantings need no protection at all. As to the common or more ordinary kinds they may either be bedded like the others, or diſtributed about the open borders in little patches of three or four roots in each, in aſſemblage with other border flowers. See their *General Culture*.

[2]RANUNCULUS *aconitifolius*.

*Aconite-leaved White-mountain Crow-foot, or Fair-maid of France.*] Hath a ſtrong fibrous perennial root joined in a head, crowned with large quinate, or five-lobed leaves, all the lobes ſpear-ſhaped, cut, and ſerrated; upright, ſtrong, flower-ſtalks, a foot and half or two feet high, divided into many branches, garniſhed with ſmall leaves like the lower ones, and all the branches terminated by pure white flowers, appearing the end of May and beginning of June.

*Varieties*] Common ſingle-flowered,—Larger double-flowered, very beautiful, and worthy of a place in every garden.

[3]RANUNCULUS *Acris*.

*Upright Meadow Ranunculus, or Yellow, Crow foot.*] Hath a fibrous cluſtered root, joining in a head, crowned by tripartite-multifid, or much divided leaves; upright flower-ſtalks a foot high, branching at top, having the upper-leaves cut into many narrow ſegments, and all the branches terminated by a bright yellow flower, appearing in May.

*Varieties*] Common ſingle-flowered of the paſtures,—Double-flowered of the gardens,——Proliferous double-flowered, one flower growing out of the middle of another. The double kinds only are proper for garden-culture.

This ſpecies in its ſingle ſtate is found in abundance in every paſture ground, and is ſeldom admitted into gardens; but the double varieties are very pretty, and merit a place in every good collection of perennials.

[4]RANUNCULUS *repens*.

*Creeping, or running Yellow Crow-foot.*] Hath fibrous, perennial roots, crowned with compound leaves, trailing, creeping, ſhoots, rooting as they run along, and furrowed pedunculi terminated by bright yellow flowers, having ſpreading cups; flowering in May and June.

*Variety.*] Common ſingle-flowered of the meadows and paſtures,—Double flowered of the gardens.

[5]RANUN-

[5]RANUNCULUS *Ficaria.*

*Ficaria, Fig-wort, or Pile-wort.*] Hath a grumous or bundled tuberous root, heart-ſhaped, angular, ſmooth leaves, on ſtrong foot-ſtalks, and upright ſimple ſtalks four or five inches high, terminated by large ſhining yellow flowers, in March and April.

*Varieties.*] Common ſingle-flowered of the meadows, &c.—Double-flowered of the gardens.

[6]RANUNCULUS *Amplexicaulis.*

*Amplexicaulous, Plantain-leaved, Alpine Ranunculus.*] Hath a bundled perennial root, oval, acuminated leaves embracing the ſtalk, the ſtalk riſing from ſix to eighteen inches high, branching and terminated by ſeveral ſingle white flowers; appears in April.

[7]RANUNCULUS *Gramineus.*

*Gramous or Graſs-leaved Pyrenean Ranunculus.*] Hath a bulbous perennial root, ſpear-ſhaped, narrow, graſſy, ſeſſile leaves; upright ſtalks about a foot high, branching upwards, each branch terminated by a ſmall, pale, yellow flower; appearing in May.

*Varieties.*] Common ſingle-flowered, — Double-flowered.

[8]RANUNCULUS *Grandiflorus.*

*Great Yellow-flowered Oriental Ranunculus.*] Hath a fibrous perennial root, multifid or many-parted leaves; erect ſtalks a foot or more high, garniſhed with two alternate cloſe-ſitting leaves; and terminated by one large yellow flower; appearing in May.

The flowers of all the above eight ſpecies of *Ranunculi* in their ſingle or characteriſtic ſtate, conſiſt each of five obtuſe bright petals, and the middle filled with numerous ſtamina, &c. ſucceeded by abundance of ſeed; but in the double-flowered varieties the petals are multiplied in many ſeries, which in the full doubles are continued to the very centre, like a double-roſe, in which conſiſts their excellence as garden-flowers for ornament: though in theſe very luxuriant or full double-flowers, the multiplicity of petals often ſupplant all the ſtamina that no ſeed is produced. This however is amply compenſated by the ſingles and half-doubles, which are ſucceeded by great plenty of ſeed, ripening in June and July; but it is only of the *Aſiatic Ranunculus* that ſeed is required, which in this ſpecies in particular is always productive of a great variety of new ſorts, but not in any of the other ſpecies, remarking, that the fineſt ſemi-doubles are the ſorts from which to ſave the ſeed for propagation.

All the ſpecies are perennial in root, and annual in leaf and ſtalk, which riſe in ſpring and decay in ſummer and autumn ſoon after they have flowered; the roots of all the ſorts being abiding, encreaſe abundantly by off-ſets every year for propagating the particular varieties.

Conſidered as garden-flowers, all the ſorts demand attention, the Aſiatic kinds however ſtand foremoſt conſiderably in point of beauty, elegance, and variety, but ſome of all the ſorts are proper furniture for the borders and other compartments of the pleaſure-garden, where being diſpoſed in aſſemblage they will effect a good diverſity in flower for two or three months, and ſome of the fineſt of the Aſiatic varieties ſhould alſo be depoſited in beds by themſelves, as before obſerved, in order to exhibit a grand blow together; obſerving that the roots of the fine varieties of this ſpecies ſhould be lifted every year after blowing to ſeparate the off-ſets and freſh prepare the mould, &c. but all the other fibrous-rooted ſpecies being diſtributed about the borders may remain undiſturbed two or three years, or as it ſhall ſeem neceſſary according as they may want trimming to keep them within bounds, or to have the roots taken up occaſionally to part them for propagation.

*Culture of the Aſiatic Kinds.*

The *Aſiatic Ranunculus* in particular is in high eſtimation among the floriſts, and is deſervedly an object of admiration on account of the great number of the varieties and the beauties the flowers poſſeſs, in their elegance of form and vaſt variety and richneſs of colour render them ſuperior to moſt other flowers of the ſeaſon, and highly merit culture in every garden.

This ſpecies in all its varieties will ſucceed in any light, rich, garden earth; but the floriſts often prepare a particular compoſt for the fine varieties, conſiſting of good garden mould or paſture-earth, ſward and all, a fourth-parth of rotted cow-dung, and the like portion of ſea-ſand; (ſee COMPOST;) and with this they prepare beds four feet wide and two deep: however in default of ſuch compoſt, uſe beds of any good light earth of your garden; or if neceſſary it may be made light and rich with a portion of drift-

drift-ſand and rotten dung, cow-dung is moſt commonly recommended; but they will alſo thrive in beds of well wrought kitchen-garden earth, and they often proſper well in the common flower borders.

The ſeaſon for planting the roots is both in autumn and ſpring; the autumn plantings generally flower ſtrongeſt and ſooneſt by a month at leaſt, and are ſucceeded by the ſpring planting in May and June. Perform the autumnal planting in October and early part of November, but ſome plant towards the latter end of September in order to have a very early bloom; but thoſe planted in that month and beginning of October often come up with rank leaves ſoon after, in winter, ſo as to require protection in hard froſts; thoſe however planted about the middle or latter end of October and beginning of November rarely ſhoot up ſtrong till towards ſpring and will not require ſo much care of covering during winter; and the ſpring planting may be performed the end of January or beginning of February, or as ſoon as the weather is ſettled; they will not require any trouble of covering, and will ſucceed the autumnal plants regularly in bloom, and will flower in good perfection. Thus by two or three different plantings you may obtain a ſucceſſion of theſe beautiful flowers in conſtant bloom from April till the middle of June; but the autumnal plants for the general part not only flower ſtrongeſt, but the roots encreaſe more in ſize, and furniſh the beſt off-ſets for propagation: it is however proper to plant both in ſpring and autumn.

Prepare for the choicer ſorts four-feet beds of light earth, as aforeſaid, by good digging, breaking the earth fine, but not ſift any part thereof, laying them of a rounding form, and rake the ſurface ſmooth, then plant the roots in rows lengthwiſe the beds, either by drilling them in two inches deep and ſix inches diſtance in the row, and the rows ſix or eight aſunder, or may plant them by bedding-in or by dibble-planting the ſame depth and diſtance. See PLANTING.

Thoſe deſigned for the borders ſhould be planted generally towards the ſpring in little clumps or patches, three, four, or five roots in each, putting them in either with a dibble or trowel two or three inches deep, and three or four aſunder in each patch, and the patches from about three to five or ten feet diſtance, placing them rather forward in the border.

As to their general culture after planting, obſerve in winter, that ſuch of the forward autumnal-planted roots of the choice ſorts in beds as have ſhot above ground, ſhould have occaſional ſhelter from hard froſts by mats ſupported on low hoop-arches; or in very ſevere weather may cover them cloſe with dry long litter, but remove all covering in open weather: and in the ſpring when the flower-buds begin firſt to advance, it will be of much advantage to ſhelter them in froſty nights with ſupported mats, ſuffering them however to be open to the full air every day; but the latter plantings that do not come up in winter or very early in ſpring whilſt froſty nights prevail, will not require any protection, and all thoſe diſtributed in patches about the borders muſt alſo take their chance in all weathers; thoſe of the different ſeaſons of planting will ſucceed one another in flowering from the beginning of April until the middle of June, though the May blow generally ſhews to the greateſt perfection.

After the blow is paſt and the leaves and ſtalks withered, take up the roots, and dry them in the ſhade, then clear them from all off ſets and adhering mould, and put them up in bags or boxes till next planting ſeaſons, when they muſt be planted again as before directed.

But in each ſeaſon of planting, it is highly neceſſary to plant them either in entire new beds, or the old refreſhed with ſome freſh rich earth or compoſt, working the old and new well together, this being neceſſary in order to invigorate the growth of the plants.

*Their Propagation.*

All the varieties of the *Aſiatic Ranunculus* propagate abundantly by off-ſets from the root, and new varieties are gained by ſeed.

By off-ſets.—The time for ſeparating the off-ſets is in ſummer when the flower is paſt, and the leaves and ſtalks are withered, then taking up all the roots in dry weather, ſeparate the off ſets from each main root, and after drying the whole gradually in ſome ſhady airy room, put them up in bags in the dry till the autumn and ſpring ſeaſons of planting, then plant them as before, placing all the off-ſets in ſeparate beds, many of them will blow the firſt year, but in the ſecond they will all flower in good perfection.

By ſeed.—Save a quantity of ſeed from the fineſt ſemi-double flowers, and ſow it either in Auguſt or in March or April, though

to ſave trouble of winter covering ſome prefer the ſpring; it ſhould be ſowed in light rich mould, either in pots or in an eaſt border, drawing very ſhallow flat drills five or ſix inches aſunder, in which ſow the ſeeds thinly, and cover them lightly with earth, giving frequent refreſhments of water in dry weather, and in a month or ſix weeks the plants will riſe with ſmall leaves; obſerving to continue the light waterings in dry weather to preſerve the ſoil moiſt during their ſummer's growth to encreaſe the ſize of the roots; and in June when the leaves decay, take up the roots and preſerve them till the ſeaſon for planting, then plant them in common beds, as before directed, and they will flower the ſpring following, when all the doubles of good properties ſhould be marked, and the ſingles thrown away.

*Culture of the other ſeven Sorts.*

All the other ſeven ſpecies of *Ranunculi* ſucceed in any common ſoil and ſituation, ſo may be diſperſed about the different flower compartments, where they may conſtantly remain, only trimming them occaſionally once in a year or two, or when they have encreaſed into large bunches they may be taken up in autumn or ſpring to divide them for farther encreaſe, and replant them again directly.

Their propagation is very eaſy, for they multiply exceedingly by the roots.

So that when intended to propagate them the roots may be ſlipped or parted in autumn when paſt flowering, or in the ſpring before they begin to ſhoot, and the ſlips may either be planted at once where they are to remain, or in nurſery rows for a ſeaſon, then planted out finally.

RAPHANUS, *Radiſh.*

The plants are herbaceous, annual, eſculents of the kitchen-garden, valuable for their eatable roots for ſpring and ſummer ſervice, having fuſiforme and globoſe roots in different varieties, broad rough leaves, and cruciforme flowers.

Claſs and order, *Tedradynamia Siliquoſa.*

*Characters.*] CALIX, four oblong, erect, deciduous leaves,——COROLLA, four heart-ſhaped, ſpreading, cruciforme petals, and four melliferous, glands,———STAMINA, four long and two ſhort filaments, having ſimple antheræ,—PISTILLUM, an oblong ventricoſe germen, ſcarcely any ſtyle, crowned by a capitated ſtigma,—PERICARPIUM, an oblong, gibbous, or ſwelling, ſmooth, bilocular pod, filled with roundiſh ſeeds.

This genus retains three ſpecies, one of which only, *Common Radiſh*, is for our purpoſe; obſerving, the botaniſts admit but of one ſpecies of this ſort, all the different ſorts of the taper-rooted and round Radiſh, both red, purple, white, and black ſorts, are ſuppoſed varieties only of the ſame ſpecies; and, indeed, we may often obſerve here and there ſome of all the varieties degenerate both in ſhape and colour; however by care in ſaving the ſeeds of the different ſorts ſeparate and diſtant from one another, the different varieties are continued diſtinct.

The ſpecies is,

*Raphanus Sativus.*

*Cultivated or common Garden Radiſh.*] Hath taper and round fleſhy roots, crowned by broad, rough leaves; and when they ſhoot for ſeed, ſend forth upright, ſtrong, widely, branching ſtalks, a yard or more high, having all the branches terminated by whitiſh cruciforme, light purpliſh flowers, ſucceeded by taper ſwelling pods with two cells.

The botanic diſtinction is, — *Raphanus* with taper, ſwelling, bilolucular pods.

*Varieties.*] All the varieties, though many of them appear as diſtinct ſpecies by the ſhape and colour of the root, yet as they all bear exactly the above ſpecific diſtinction in the ſeed-pod, they are conſidered all as varieties only of one another, belonging all to the ſpecies *Raphanus Sativus*, and the principal ſorts are the following, which may be divided into two claſſes,—Common taper-rooted Radiſhes,---and Turnep rooted kinds.

*Common Taper-rooted Kinds.*

*Short-topped Radiſh.*——Having an oblong taper, reddiſh purple root, ſome deep, others pale-coloured, crowned with only a ſmall ſhort top of leaves, which is a particular merit peculiar to this ſort, as the plants require both leſs room to grow, and the root ſwells faſter in proportion, attaining perfection much ſooner than the large-topped kinds, being alſo a firm, criſp, tender-eating Radiſh, ſo is preferable for general culture, both for all early crops in frames and borders, and for the general crops in the open quarters; the pale-rooted ſort is generally milder to eat than the deep red or purple kind.

This

This may be ſowed at different times, from October or November until May; but from January till March and April is the general ſowing ſeaſon, at two or three weeks intervals, for the main crops.

*Salmon-coloured Radiſh.*] Having a fine long, taper, pale-ſcarlet root, crowned generally with a pretty large top of leaves, but if allowed room, the root ſwells freely to a handſome ſize, and is a firm, criſp, excellent Radiſh for the later crops, ſowed in March, April, and May, in open ſituations.

*Variety.*] Short-topped early Salmon Radiſh.

*Long-topped Red Radiſh.*] Having an oblong, taper, red root, crowned with a large top of leaves;—not proper for general culture.

*Deep-red Radiſh.*] Having an oblong, taper, deep-red root, apt to become ſoon hot and ſticky; not proper for general culture.

*Sallad Radiſh.*] Any ſort of Radiſh may be uſed as ſuch, being ſowed thick like creſſes, and muſtard, to gather whilſt young in the ſeed leaf, to mix in ſallads; but ſeed of any of the common long-topped ſorts may be ſowed for this purpoſe. See SALLAD HERBS.

*Turnep-rooted Kinds.*

*Small White Turnep-rooted Italian Radiſh.*] Having a ſmall, round, turnep ſhaped, white root, being very like young Dutch turneps; and if uſed whilſt quite young, they eat very criſp, mild, and well taſted, and make an agreeable variety at table; are in higheſt perfection in April and May, or in autumn: ſow them in February, March, and April, for ſpring uſe; and end of July or beginning of Auguſt, for autumn eating.

This ſort is often brought to the London markets in the ſpring, about April and beginning of May, generally in bunches, and are often miſtaken for young turneps.

*Large, white, Turnep-rooted Spaniſh Radiſh.*] Having a moderately-large, round, orbicular, turnep-ſhaped, white root, eſteemed chiefly for autumn eating, and early part of winter; ſowing them in July and beginning of Auguſt.

*Black Turnep-rooted Spaniſh Radiſh.*] Hath a large, roundiſh oblong, black-coated root, but white within, greatly eſteemed by many for autumn and winter eating, either alone or ſliced in ſallads: ſow them in open ground in July and beginning of Auguſt, they will come in for uſe in September and October, and continue in perfection all winter.

All theſe varieties of *Raphanus Sativus* are annual plants, which being ſowed in the ſpring attain perfection in two or three months, and ſhoot up ſoon after into ſtalk for flower and ſeed, which, ripening in autumn, the whole plant, root, and top periſhes; ſo that a freſh ſupply muſt be raiſed annually from ſeed in the ſpring, performing the ſowings at ſeveral different times, from about Chriſtmas until May, in order to continue a regular ſucceſſion of young tender Radiſhes throughout the ſeaſon; allowing only a fortnight or three weeks interval between the ſowings, for one crop will not continue good longer than that ſpace of time, before they will either run to ſeed, or become tough, ſticky, and hot to eat.

They are all tolerably hardy, except very early raiſed plants in their infant ſtate, which are liable to ſuffer by froſt; and they all ſucceed in any common garden earth, and almoſt any ſituation and expoſure open to the ſun and free air; though for the early crops a warm ſouth border, or other ſheltered ſunny ſituation, is proper, both to bring the crop forwarder, and for protecting the plants from cold, as being impatient of froſt whilſt young, as aboveſaid; therefore when they riſe early it is proper to cover them in froſty nights with ſtraw or mats; but the main crops ſowed in February and March, &c. may be in any open ſituation, as they want no protection.

*Culture of the common Spindle-rooted Radiſh.*

To have Radiſhes as early as poſſible, they are ſowed both on warm borders and in hotbeds, under frames and lights.

But firſt of their culture in the open ground. To have early Radiſhes in warm borders, you may begin ſowing a few ſhort-topped Radiſh in October, November, and December, but not any general early ſowing till about Chriſtmas, or early in January, if the weather is open; or in cold wet grounds not till the end of that month or beginning of February; for the very forward ſowings performed before the middle or end of December, are not to be depended on, though ſuch of them as ſurvive the winter's froſt, will be fit to draw ſometimes in January and February; they however will be hard and ſticky; but as they may be deemed a great rarity at a very early ſeaſon, and as the ſeed is cheap enough, and

a ſmall ſpace of ground will be ſufficient, it may be worth the trial to ſow ſome in the middle or end of October, and a few more in November and December, and let them take their chance of the winter; and if they ſhould fail, the ſame ground will do to ſow again time enough for a good ſpring crop. However, for the general early crop, the end of December, or the beginning or middle of January, according to the temperature of the ſeaſon, is time enough to begin, when, if open weather, it is proper to think of ſowing a good crop in a warm dry border, or any warm-lying light ground; and about the end of January, or beginning of February, ſow a more general crop.

Let the ground for the reception of the ſeed be trenched one good ſpade deep at leaſt; or it will be of advantage, if it has been previouſly trenched up in ridges, then levelled down, the clods well broken, and the ſurface laid even.

Then being provided with ſome good ſhort-topped Radiſh-ſeed, and with which, if you think proper, you may mix a ſprinkling of coſs-lettuce and carrots, they will come in for uſe after the Radiſhes, and be ſome weeks earlier than the main crops. Sow the whole together broad-caſt all over the ſurface tolerably thick in the early ſowings, and rake them well in with a large rake; or, if in a large open plat of ground, or where the ground is rather wettiſh or ſtiff, it is proper, for the early ſowings in particular, to divide it into four or five-feet wide beds, with foot and a half wide alleys between; then ſowing the ſeed, ſtrike it a little in with the teeth of the rake, and then caſt ſome earth of the alleys over them half an inch deep, and rake it ſmooth.

The London kitchen-gardeners, after performing the main early ſowings from about Chriſtmas till the beginning of February, generally cover the ground directly with clean wheat-ſtraw, about two inches thick, both to keep the ſurface warm, and keep off birds from the ſeed, ſuffering it to remain till the plants are fairly come up, as it contributes to their more early riſing, and is then raked off lightly every mild day.

However, covering theſe early crops is very eligible, when the plants come up, every froſty night; for this purpoſe have either a quantity of dry wheat-ſtraw, or dried fern, &c. laying it ready in the alleys, and every night, when there is an appearance of froſt, throw it over the plants with a pitchfork, two inches thick or more, if the weather ſhould prove ſevere, and rake it off lightly every mild morning with a wooden rake; but in ſevere weather muſt remain night and day: and this covering, if carefully ſpread on and taken off, will no ways bruiſe the plants, but will not only protect them from the froſt, but continue them greatly forward in their growth. But inſtead of ſtraw ſome uſe large garden-mats, eſpecially after the plants are up, and a little advanced, generally ſticking two or three rows of ſtout wooden pegs along the border or beds, in a ſlanting manner, two or three inches above ground, to ſupport the mats from the plants, or where there is only a ſmall quantity, you may arch the beds with hoops for the ſupport of the mats.

The above work of covering early Radiſhes, may to ſome appear tedious and troubleſome, but it is ſoon done when every thing is laid ready, and is univerſally practiſed by the London gardeners, to large tracts of ground, continuing it till the plants are fairly in the rough leaf, and firmly rooted; for the early quite young plants, being not only liable to be greatly cut at top by the froſt, but even thoſe expoſed thereto and ſeemingly ſurvive, are often ſtarted at the root; that is, the froſt heaving the ground, it draws the plants up along with it, and breaks the tender radicle or lower perpendicular fibre, which not only retards their growth till they form new fibres, but the terminal downright fibre being broken off, prevents their ſhooting in length, that they can never form handſome Radiſhes, but become what the market gardeners call chumps: ſo thoſe gardeners who raiſe large quantities for the ſupply of the London markets, find their account in allowing the early main crops occaſional protection, which by inſuring fuller crops coming in earlier and in greater perfection, always pay them ſufficiently for the trouble of covering.

When the Radiſhes however are a little advanced in growth, being in the rough leaf, it is proper to thin them, where they ſtand too thick, to two inches diſtance, which, as you will begin drawing them for uſe when quite young, may be room enough at preſent, as the daily thinning for the table or market will give them more and more room every day.

In very dry weather, in March and April, it is adviſeable to give them a good watering every evening or morning, which will both

forward

ward their growth conſiderably, increaſe the ſize of the root, and render them more criſp and mild to eat.

Continue repeating the ſowings every fortnight or three weeks, till March, then ſow every fortnight until the end of April; or where a long ſucceſſion of young Radiſhes is required, the ſowings may be continued all May, or even during the ſummer, until the middle or end of Auguſt, if required; thoſe ſowed in July and Auguſt will be very fine in September and October; obſerving in ſowing the latter crops of Radiſhes, from the middle of February during the reſt of the ſowing ſeaſon, they may be ſowed in any open ground, and want no covering in any weather; and in the main crops of Radiſhes, if neceſſary to make the moſt of your ground, you may mix a ſprinkling of coſs-lettuce and round-leaved ſpinach ſeed, ſowing the whole together broad-caſt, and rake them in evenly with a large rake as aforeſaid; the three crops will be coming forward all at the ſame time, without interruption to one another; the Radiſhes come in firſt, then, after theſe are drawn off, the ſpinach flouriſhes, and ſoon becomes fit for uſe, which is ſucceeded by the lettuce; and between theſe may ſow pickling cucumbers or kidney beans, &c. in the beginning of June.

But in ſowing the main general crops of Radiſhes in the open quarters, the market gardeners generally ſow them on the ſame ground where they plant out their main crops of cauliflowers and cabbages, mixing ſpinach with the Radiſh ſeed, as above ſaid, ſowing the ſeeds firſt, and rake them in, then plant the cauliflowers or cabbages; the Radiſhes and ſpinach come in for uſe before the other plants begin to ſpread much, and as ſoon as thoſe ſmall crops are all cleared off for uſe, then hoe the ground all over to kill weeds and looſen the ſoil, and draw earth about the ſtems of the cauliflowers and cabbages.

With regard to the culture of theſe general crops of Radiſhes, they require very little, which is occaſional thinning where they are too thick, performing this when the plants are come into the rough leaf, either by hoe or drawing them out by hand; though for large quantities, ſmall-hoeing is the moſt expeditious mode of thinning, as well as prove very beneficial to the crop by looſening the ground; however, in either method thin the plants to about three inches diſtance, clearing out the weakeſt, and leave the ſtrongeſt to form the crop.

Early crops in hot-beds, &c.—When it is required to have young Radiſhes as early in the ſpring as poſſible, they may be greatly forwarded by aid of hot-beds under frames and glaſſes, or other ſhelters.

This work may be begun any time in winter, if thought proper; but from Chriſtmas till Candlemas is the moſt eligible ſeaſon to enſure a thriving crop. Make a hot-bed for one or more three-light frames, about eighteen inches depth of dung, which is ſufficient, as the heat is only intended juſt to bring up the plants, and ſet them a-going a little at firſt; put on the frame directly, and earth the bed ſix or ſeven inches deep with light rich mould; then having the true ſhort-topped Radiſh-ſeed, ſow it on the ſurface of the bed moderately thick, and cover it evenly half an inch thick with light mould, and put on the lights, and the plants will come up in a week, or probably in leſs time, if there is a tolerable warmth in the bed; obſerving, when they appear, to admit air every day, either by tilting the lights conſiderably in the front or behind, according to the temperature of the weather, or in fine mild days take them quite off; for a large portion of freſh air is neceſſary every day, otherwiſe the plants will draw up to ſhank, and go off; remarking, that after the plants have had a week or fortnight's growth, they ſhould be thinned where they have riſen too thick, leaving them about an inch and a half apart; then obſerving, if the plants have unavoidably drawn up with long ſhanks, it is adviſeable to ſift ſome light mould out of a fine ſieve in amongſt them evenly all over the bed, ſo as to mould their ſhanks about half an inch or an inch, or more thick, as there ſhall be occaſion: this will greatly ſtrengthen their growth, and promote the goodneſs of the roots; ſtill remembering to indulge them with a large portion of freſh air every mild day, and cover them on nights; thus the plants will advance faſt to perfection, and be fit to draw in ſix weeks.

But in want of frames and glaſſes for the above purpoſe, you may cover occaſionally with mats, making the hot-bed as before, and mould it the ſame depth, ſecuring the ſides of the mould with boards or wreaths of ſtraw-bands; then cradle or arch it over with hoops or rods for the ſupport of the

mats, which muſt be uſed every night and all bad weather, till the plants are ready for uſe.

Or in caſe of ſcarcity of dung for making hot-beds as above, you may ſow ſome ſeed in beds of common earth under garden frames, and put on the lights every night and all bad weather; and thus you may raiſe the plants for uſe ſooner by a fortnight than in the common open borders.

*Culture of the Turnep-rooted Kinds.*

As to the turnep-rooted Radiſhes, they ſhould always be ſowed in ſome open ſituation and light ground.

The ſmall round ſort may be ſowed in ſpring, in February, March, or beginning of April; or for autumn uſe, ſow them in July and beginning or middle of Auguſt: at either ſeaſon ſow them broad-caſt thinly, and rake them in evenly, and when the plants come up and get into the rough leaf, they muſt be thinned either by hoe or hand, ſetting them out four or five inches aſunder.

The other two large turnep-rooted kinds ſhould be ſowed principally in autumn, about the middle or end of July, in any open ſituation thinly, and raked in; and when the plants have got rough leaves about an inch broad, hoe them out to ſix or eight inches diſtance, they will attain full growth for uſe in September and October, and continue good great part of winter, particularly the black ſort; however, it is proper to take up a quantity in November or December, before attacked by ſevere froſty weather, and depoſiting them in any ſheltered place in ſand, they may be kept in good perfection till the ſpring.

*Saving Seed of all the Sorts.*

To ſave Radiſh-ſeed, you may either leave ſome plants of the firſt main crops to run up, or tranſplant a quantity into an open ſpot of ground; the latter is more particularly to be recommended for general practice, becauſe, by drawing up the roots for planting, you can judge of the goodneſs in reſpect to ſhape and colour; they ſhould be planted in an open ſituation.

The proper ſeaſon therefore for planting out Radiſhes for ſeed is the beginning or towards the middle of May, juſt when the roots are in their prime, chuſing ſhowery weather if poſſible.

Obſerve of the common taper-rooted Radiſhes to ſelect them with the ſhorteſt tops, and the longeſt ſtraight roots of the beſt colours in the reſpective varieties, remarking particularly of the ſhort-topped kind, to chuſe them always with the very ſmalleſt tops, and as of this ſort there being ſome with roots of a deep reddiſh-purple colour, and others having pale-coloured clear roots, the latter of which are generally more criſp and mild than the former, and are particularly eſteemed about London; ſo that in drawing them to plant for ſeed, you ſhould keep them ſeparate, obſerving alſo the ſame of the other varieties: then havingpreviouſly digged an open ſpace of ground for their reception, plant the Radiſhes, with their leaves entire, by a dibble, in rows two feet and a half aſunder, and the ſame diſtance in the lines, placing them in the quincunx order, and each root down to its leaves, directly giving them a good watering, to ſettle the earth cloſe about the roots, and forward their ſtriking, repeating the waterings in dry weather till they have taken freſh root, and ſhew ſigns of growth.

As to the turnep-rooted kinds, ſome ſhould be ſowed in the ſpring, about March, purpoſely for ſeed, and may either remain where ſowed, hoeing them out to wide diſtances, or when the roots are arrived to perfection in May or beginning of June, a quantity may be tranſplanted, chooſing the roundeſt, beſt-ſhaped, faireſt root, and planted in rows two feet and a half aſunder, as before obſerved, and water them.

Obſerve however if any of the large turnep rooted kinds of the autumn crops ſhould ſtand the winter, ſome may be left, or planted out for ſeed in February.

All the ſorts will ſoon take root, and ſhoot up to ſtalk in June, branch widely every way, flower in July, and the ſeed will ripen in September.

Their ripening is diſcovered by the pods and ſeeds changing brown; then cut up the ſtalks, and ſpread them in the ſun a week or two to dry and harden the pods and ſeeds, and then threſh them out; obſerving the ſeed-pods being of a tough nature, they do not readily break to diſcharge the ſeed, ſo that ſometimes they require to be expoſed to the weather ſome conſiderable time, to render the huſks brittle, and ſometimes they require to be threſhed two or three times over; when they however are threſhed out, clean the ſeed from the rubbiſh, and put it up in bags out of the way of mice.

## REED HEDGES.

Reed Hedges are temporary internal fences made with dried Reeds, which may be had cheap enough all over the kingdom, and may be expeditiouſly formed into Hedges by the aſſiſtance of poſts and railing, and make a cheap temporary fence of great utility for occaſional uſe in gardens, to incloſe particular internal ſpaces of ground, to afford ſhelter to certain ſeedling plants, both in nurſeries and large kitchen gardens.

But Reed Hedges are particularly uſeful in nurſeries, to form places of ſhelter for many ſorts of ſeedling trees and ſhrubs, &c. which being tender whilſt young, require the ſhelter of a fence in winter to break off the keen edge of cutting blaſts two or three years, till they gradually gather ſtrength and a greater degree of hardineſs; theſe kind of fences are alſo uſeful in nurſeries for training ſeveral ſorts of wall fruit-trees againſt, to form them for walls in gardens, being what the nurſerymen call *Trained Trees*; ſo that theſe Reed fences being cheap and ſoon formed, are often uſed in the nurſeries for a double purpoſe, that is, ſerving both for ſhelter, and affording an opportunity of planting trees againſt each ſide eight or ten feet aſunder, for the purpoſe of training for walls as aforeſaid. See NURSERY, &c.

Likewiſe in large open kitchen gardens Reed Hedges are often employed to good advantage for ſheltering tender plants and early crops: ſuch as incloſing particular ſpaces for a melonary, or place wherein to raiſe early melons and cucumbers, and often as croſs internal fences, running acroſs the ground at conſiderable diſtances, under which forming warm borders for the purpoſe of raiſing various early crops of eſculents more plentifully; ſerving alſo to break the force of cutting and tempeſtuous winds from the crops in the adjacent quarters, and for which purpoſes many of the kitchen-gardeners about London uſe theſe kind of Hedges.

Remark however, theſe Reed Hedges are not at all adapted for outward fences, as they may be very eaſily broke through.

But as internal fences for ſheltering plants, they are accounted better than walls or pales, becauſe the Reeds generally deaden the winds without reverberating them back again.

The proper Reeds for making theſe fences are the dried ſtems of the *Arundo Phragmitis*, or Common Marſh Reed, which, growing in great abundance by river ſides, lakes, and marſhy places all over the kingdom, furniſh a crop of ſtems annually fit to cut in autumn, and being then bound in bundles, are ſtacked up or houſed to remain for uſe; and great quantities are annually brought to London by water, and depoſited in warehouſes near the river, where they have great demand for them among the gardeners for making Reed fences.

As to the method of making theſe fences, they are ſometimes erected in fixed ranges, and ſometimes formed into moveable pannels. When to be formed into fixed fences, arrange ſome ſtout poſts ſix or eight feet aſunder, and five or ſix high, and from poſt to poſt carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; againſt this railing place the reeds two or three inches thick, having other railing fixed directly oppoſite, ſo that the Reeds being placed all along between the double railing, the bottoms reſting either upon a plate of wood, or let into the ground, as may be convenient; and as ſoon as one pannel is placed, nail the railing as cloſe as poſſible, and either drive ſome long ſpike nails through each double railing, or bind them with ſtrong withy bands, but nailing is the beſt, in order to bring them as cloſe as may be, to ſecure the Reeds firmly in the proper poſition; and thus proceed till you have completed the range of fencing.

But when intended to have any of theſe fences formed into moveable pannels, to remove to different places occaſionally, a frame-work of railing is prepared as above, each pannel ſix or eight feet long, and the Reeds fixed therein as before directed; then whereſoever it is intended to place them, poſts muſt be ranged ſix or eight feet diſtance, to ſupport the ſeveral pannels.

## RESEDA, Baſtard Rocket, *Mignionette*, &c.

It conſiſts principally of herbaceous annuals, biennials, and perennials; ſome of the biennials in particular merit culture, one as an odoriferous garden plant, another for field culture, for the uſe of the dyers, &c. growing from one to three feet high, having oblong and lanceolate leaves, and terminated by ſpikes of ſmall unequal flowers.

Claſs and order, *Dodecandria Trigynia*.

*Characters.*] CALIX, is monophyllous, many-parted, and permanent. COROLLA, ſeveral ſmall, unequal, generally trifid petals, the upper being gibbous at the baſe, contain-

containing a honey juice, and a glandular, plane, erect nectarium at the upper ſide of the receptacle, between the ſtamina and upper petal, connivent with the baſe thereof. STAMINA, twelve or fifteen ſhort filaments, having obtuſe erect antheræ. PISTILLUM, a gibbous germen, three or more very ſhort ſtyles, having ſimple ſtigmas. PERICARPIUM, a gibbous, angular, unilocular capſule, with apertures between the ſtyles, having many kidney-ſhaped ſeeds adhering to the angles of the capſule.

There are many ſpecies, the moſt noted of which, for our purpoſe, are the two following, the firſt for the pleaſure-ground, the other for field culture.

'RESEDA *Odorata*—(*biennial* and *tender*.)

*Odoriferous Reſeda, commonly called Mignionette.*] Hath a tough fibrous root, ſending forth ſeveral weak branchy ſtalks, growing twelve or eighteen inches long, having oblong, entire, and trilobate leaves, and all the branches terminated by long ſpikes of greeniſh-white ſweet-ſcented flowers, having the calix equal with the petals.

This plant is biennial, is in high eſtimation for its agreeable fragrance, though is not ornamental neither in its growth nor flowers, but the latter impart a moſt delightful odour widely around, flowering in ſummer, continuing ſeveral months, even all winter, if ſheltered in a green-houſe, &c.

Is a native of Egypt; ſucceeds here in the open air in ſummer, but requires ſhelter in winter.

RESEDA *Luteola*—(*biennial* and *hardy*.)

*Luteola, or Yellow Herb, commonly called Weld, Wild Woad, or Dyer's Weed.*] Hath tough fibrous roots, crowned with long, narrow, ſpear-ſhaped, entire leaves, ſpreading on the ground, upright ſtems a yard high, garniſhed alſo with ſpear-ſhaped narrow leaves, and terminated by long looſe ſpikes of yellow flowers, having quadrifid cups; grows wild on old walls and the ſides of banks and ſterile places in England, &c. but is cultivated in fields for its flower-ſtems, for the uſe of the dyers.

Both theſe ſpecies are biennial plants, the firſt is ſomewhat tender, requiring ſhelter from froſt; but the ſecond is very hardy; obſerve however the firſt ſort may be deemed annual as well as biennial, for being ſowed early in ſpring, will flower and perfect ſeeds the ſame year, and totally periſh in winter, if not ſheltered; but being ſheltered all winter in a green-houſe, they will continue till next ſummer: the ſecond ſort however is perfectly biennial; for being ſowed one year, it does not run up to ſtalk till next ſummer, when it flowers and ripens ſeed, and wholly decays ſoon after.

*Method of Propagation.*

They are both raiſed from ſeed ſowed annually, the firſt ſort principally in a hot-bed, the other in the open ground.

The *Odoriferous Reſeda*, or *Mignionette*, ſhould be ſown in March or April, in any moderate hot-bed, as directed for tender annuals, ſowing ſome in ſmall pots to remain, and ſome for tranſplantation into the full ground, in the end of May or June; however, whilſt they remain in the hot-bed, indulge them with freſh air daily, and occaſional waterings in common with the other plants; and if ſome were pricked upon a freſh hot-bed, or into ſmall pots, three plants in each, and plunged in the hot-bed, it will forward them conſiderably: in the end of May or in June, according to the ſtrength of the plants and temperature of the ſeaſon, taking opportunity of mild moiſt weather, remove them into the full air, retaining ſome in pots, others tranſplant with balls into the borders, obſerving, when the ſtalks of the plants advance, to place ſhort ſticks for their ſupport, and to which tie the ſtems in a neat manner.

But the ſeed of this plant will alſo grow in the full ground, ſowed in the middle of April and in May, when the ſeaſon is become warm and ſettled, ſowing them in light earth, either in a bed by themſelves, and raked in lightly, or in patches about the flower-borders, covering them a quarter of an inch deep; and in either method ſuffer the plants to remain where raiſed, giving occaſional waterings.

And if ſome plants are raiſed in pots in May, or any time in ſummer, or towards autumn, and the pots plunged in an eaſt border, or where they may have only the morning ſun, well watered all ſummer, and in October placed in a green-houſe, they will ſtand the winter, and ſome of them raiſed forward in the ſummer, will flower all the winter ſeaſon, others raiſed towards autumn, will continue increaſing in growth, and flower ſtrong early next ſpring and ſummer.

They ripen ſeeds in September, when they ſhould be carefully gathered in dry weather.

The

The culture of the Weld, or Wild Woad, is generally in large quantities in fields, and thrives in any poor land, though it will conſequently be more proſperous in a rich ſoil; the beginning of Auguſt is the beſt ſeaſon for ſowing it, allowing about one gallon to an acre, and ſow it broad caſt evenly, and harrow it in; the plants will ſoon come up the ſame ſeaſon, and when they are a little advanced in growth, hoe them to thin the crop and kill weeds, leaving the plants ſix inches aſunder; they will ſhoot up into ſtalk next ſpring, and flower in June, at which time the plants ſhould be pulled for uſe, laid to dry, then tied in bundles and houſed.

A quantity of the plants ſhould be ſuffered to ſtand every year for ſeed.

RHAMNUS, (*Cerva ſpina*) Buckthorn.

The plants are of the tree and ſhrub kind, compriſing ſeveral deciduous and evergreen ſpecies for adorning the pleaſure-ground and green-houſe collection, garniſhed with oval and oblong leaves, and ſmall infundibuliforme flowers moſtly in bunches, ſucceeded by ſmall round berries.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, is monopetalous, funnel-ſhaped, four or five-parted, and ſpreading, having a ſmall ſcale at the baſe of each diviſion. STAMINA, five, or generally as many filaments as there are diviſions in the corolla, inſerted under the ſquamulæ or ſcale of the petal, and terminated by ſmall antheræ. PISTILLUM, a roundiſh germen, filiforme ſtyle, crowned by an obtuſe ſtigma, and divided into fewer ſegments than the corolla. PERICARPIUM, a round naked berry of three or four cells, having the like number of roundiſh hard ſeeds.

Late improvements in botany have ranged ſeveral genera of former authors as ſpecies only of this genus, ſuch as the *Frangula*, or Berry-bearing Alder,—*Paliurus*, or Chriſt's Thorn,—*Alaternus*,—and *Zizyphus*, or Jujub-tree; all of which bearing the *characters* exactly of *Rhamnus*, are to be now conſidered as ſpecies of that genus.

They conſiſt of deciduous and evergreen kinds, moſtly of hardy growth, and ſome of tender quality.

*Hardy deciduous Kinds.*

Under this head is compriſed the common Buckthorn, *Frangula*, and *Paliurus*.

[1]RHAMNUS *Catharticus.*

*Cathartic, or Common Purging Buckthorn.*] Grows twelve or fourteen feet high, branching numerous and irregularly, ſmooth, and armed with ſharp ſpines, oval, ſpear-ſhaped, ſawed, ſmalliſh leaves, on long foot-ſtalks, and at the ſides of the branches cluſters of ſmall, quadrifid, dioeceous, greeniſh flowers, ſucceeded by black berries in autumn, having four ſeeds.

*Varieties.*] Dwarf Buckthorn, growing about a yard high—Dwarf long-leaved Buckthorn, growing five or ſix feet high.

The common ſort grows wild in hedges in many parts of England, but is admitted for variety in the ſhrubbery plantations; the berries of it are uſed in medicine, being made into a ſyrup, good for many diſorders, given as a cathartic or purge, ſaid to be good to purge watery humours, and againſt the dropſy, jaundice, itch, and all eruptions of the ſkin, &c.

[2]RHAMNUS *Frangula.*

*Frangula, or Common Berry-bearing Alder.*] Riſes with a woody ſtem, branching numerouſly ten or twelve feet high, without thorns; oval-ſpear-ſhaped, entire leaves, two inches long; and ſmall, monogynious, hermaphrodite, greeniſh flowers, terminating the ſhoots in cluſters, ſucceeded by round berries, ripening to a black colour in autumn, having generally but two or three ſeeds.

*Varieties.*] Dwarf Berry-bearing Alder, growing two or three feet high——Dwarf long-leaved.

The common ſort is an inhabitant of our woods in many parts of England, but has been long admitted in garden plantations, to increaſe the variety of hardy deciduous ſhrubs.

[3]RHAMNUS *Alpinus.*

*Alpine rough-leaved Berry-bearing Alder.*] Riſes with a woody ſtem, branching numerouſly twelve or fourteen feet high, without thorns; larger oval-ſpear-ſhaped rough leaves, doubly crenated; and dioeceous flowers.

*Variety* ] Smooth-leaved Alpine *Frangula.*

[4]RHAMNUS *Paliurus*, (*Spina Chriſti*).

*Paliurus, or Chriſt's Thorn.*] Riſes with a ſhrubby ſtem, branching ten or twelve feet high, having numerous weak pliant branches, armed with ſharp thorns by pairs, at every joint, having the lower one reflexed; oval leaves alternately, near an inch long, and trigynous yelloviſh flowers in cluſters at the axillas of the branches, ſucceeded by ſmall, roundiſh,

roundiſh, compreſſed berries, ſurrounded by a membraneous border.

It grows naturally in Paleſtine; alſo in Spain, Portugal, and ſome parts of France, and is retained here in our ſhrubberies as a curioſity; as being ſuppoſed to be the plant of which the crown of thorns was compoſed, to place on the head of our Bleſſed Saviour at his crucifixion, the probability of which is ſupported by accounts of ſome travellers, by obſerving that the ſhrub grows naturally in great plenty about Jeruſalem and in Judea.

All the above deciduous ſpecies flower about June, but the flowers are not ornamental, being ſmall and moſtly of a greeniſh colour, which in the firſt three ſpecies are ſucceeded by abundance of berries in autumn, effecting a tolerable variety; but the *Paliurus* rarely ripens its berries in England.

They are all hardy ſhrubs, and will proſper in any common ſoil, and may be planted to increaſe the variety of the ſhrubbery and other hardy plantations.

They are propagated by ſeed and by layers, and ſometimes by cuttings.

By Seed.—In autumn, or as ſoon as the ſeeds can be procured after they are ripe, ſow them in light earth, covering them near an inch deep; they ſometimes riſe the ſpring following, if ſowed early in autumn, otherwiſe are apt to remain a year longer in the ground; when however the plants are a year or two old, plant them out in nurſery-rows, to have two or three years growth, and then may be planted out finally.

By Layers.—Chuſe the young ſhoots in autumn, and give them either a little twiſt or nick in the bark at a joint, then lay them in the uſual way, they will be rooted in one year.

By Cuttings.—The firſt three ſorts in particular grow by this method; chuſe the young twigs for cuttings in autumn, and plant them in rows, moſt of them will ſtrike.

*Evergreen Kinds.*

Of theſe ſorts there is but one ſpecies common to our gardens, which was formerly a diſtinct genus (*Alaternus*), but now a ſpecies of *Rhamnus*, and comprehends ſeveral varieties——all beautiful, hardy, evergreen ſhrubs.

5 RHAMNUS *Alaternus.*

*Alaternus.*] Riſes with a ſhrubby upright ſtem, branching numerouſly all the way from the bottom, from four or five to twelve or fifteen feet high, the branches having a ſmooth, greeniſh, and reddiſh bark, cloſely garniſhed with oval, ſtiff, ſhining green, ſerrated leaves, placed alternately, and at the axillas dioeceous greeniſh flowers in cluſters, with three-parted ſtigmas, ſucceeded by round ſoft berries in autumn, having three ſeeds.

It is a native of the ſouthern parts of Europe.

*Varieties.*] Large-growing Alaternus—— Small-growing Alaternus—Broad leaved Alaternus—Narrow jagged-leaved Alaternus —Gold ſtriped-leaved—Silver ſtriped-leaved —Blotched-leaved—Yellow-ſtriped jagged-leaved—White-ſtriped, jagged-leaved—All of which are evergreen ſhrubs, varieties of the ſame ſpecies, and of hardy growth, ſucceeding in any common ſoil in the open ſhrubberies and other plantations, and exhibit a very ornamental appearance the year round.

This ſpecies and the *Phillyrea* bearing a great external reſemblance, are often miſtaken for one another, but the *Alaternus* in all its varieties have the leaves placed alternately, and the *Phillyrea* in pairs oppoſite, ſo that there is a very obvious diſtinction, beſides being of different genera by the *characters* of their flowers and fruit. See PHYLLYREA.

All the varieties of the *Alaternus* are very ornamental evergreens for adorning the ſhrubbery and wilderneſs compartments, and if the plain green ſorts and variegated kinds are intermixed in aſſemblage with other evergreens, they will effect a very diſtinguiſhable variety at all ſeaſons: theſe plants were alſo formerly uſed for ornamental hedges, and at preſent are often employed to form hedges as blinds to hide any naked wall, or other diſagreeable ſence, &c. in fore-courts and other conſpicuous places contiguous to the dwelling; the variegated kinds being moſtly uſed for this purpoſe, or the green and ſtriped ſorts intermixed, which being planted cloſe againſt the fence, two or three feet aſunder, and their branches nailed thereto, they will ſoon cover it effectually.

They are propagated by ſeed and by layers; the plain green ſorts may be raiſed by both methods, but the variegated ſort by layers only.

By Seed.—The berries ripening abundantly in September or early part of October, ſhould be gathered and ſowed as ſoon after as poſſible, otherwiſe they will hardly come up till

till the ſecond ſpring. Sow them in beds of light mould an inch deep, they will probably ſome come up in the ſpring; but if not, keep the beds weeded and they will all come up the ſpring following; which, after having two years growth, tranſplant them in March in nurſery rows, to remain till wanted for the ſhrubbery, &c.

By Layers—All the ſorts may be raiſed this way, which is the only certain method to continue the variegated ſorts. Chuſe the young ſhoots of the year in autumn, give them a ſlit at a joint, and lay them, they will be moſt of them well rooted by the autumn following; then take them off and plant them in the nurſery way, to have two or three years growth.

*Green-houſe and Stove Kinds*

Conſiſt principally of ſome ſpecies of *Zizyphus*, formerly a genus of itſelf, but now ranged in the family of *Rhamnus*; and the following are cultivated in ſome gardens for variety.

The two firſt are green-houſe plants and the other two for the ſtove.

[6]RHAMNUS *Zizyphus.*

*Common Zizyphus, or Jujube tree.*] Riſes with a woody ſtem, branching irregularly eight or ten feet high, armed with ſtrait prickles by pairs; oval, oblong, ſmooth leaves, and ſmall digynous cloſe-ſitting yellow flowers, ſucceeded by large oval berries.

[7]RHAMNUS *Jujuba.*

*Indian Jujube Tree.*] Riſes with a ſhrubby ſtem, branching eight or ten feet high, armed with ſolitary or ſingly-placed recurved ſpines, roundiſh retuſe leaves, downy underneath, and aggregate pedunculi ſupporting ſmall, ſemi-digynous, yellowiſh flowers, ſucceeded by large round berries.

[8]RHAMNUS *Spina Chriſti.*

*Spina Chriſti, or Æthiopian Jujube.*] Riſes with ſhrubby ſtems dividing into ſlender branches, armed with ſtrait ſharp ſpines by pairs; oval leaves, and ſmall yellowiſh flowers.

[9]RHAMNUS *Oenoplia.*

*Oenoplia, or Ceylon Jujube.*] Riſes with a with a woody ſtem, branching eight or ten feet high, armed with ſolitary recurved ſpines; roundiſh heart-ſhaped leaves, and aggregate almoſt cloſe-ſitting pedunculi ſupporting yellowiſh flowers.

Of the above four kinds, the two firſt are for the green-houſe collection, the other two for the ſtove; ſo muſt always be kept in pots, and placed among the plants of thoſe departments.

They are propagated by ſowing the ſtones of the fruit in pots, and plunged in a hot-bed.

Likewiſe by ſuckers from the root and by layers.

RHEUM, Rhubarb.

The plants are luxuriant herbaceous perennials, of tall upright growth; for variety in gardens and medical purpoſes; having very thick, fleſhy, branched roots; crowned with ſingularly large, ſimple, roundiſh foliage, one or two feet in length and breadth; and ſtrong erect annual ſtalks, from about three to ſix or eight feet high, terminated by large ſpikes of numerous ſmall ſix-parted flowers.

Claſs and Order, *Enneandria Trigynia.*

*Characters.*] CALIX none. COROLLA is monopetalous, narrow at the baſe, and impervious, divided above into ſix parts, alternately ſmaller. STAMINA, nine capillary filaments inſerted into the corolla, and terminated by oblong didymous antheræ. PISTILLUM, a ſhort triquetrous germen, ſcarcely viſible ſtyles, and three reflexed plumoſe ſtigmas. PERICARPIUM, none, one large trequetrous, acute ſeed to each flower, having a membraneous border.

There are about five ſpecies, all herbaceous and of foreign growth, but grow freely here in the open ground. Are in great eſtimation as medical plants, the root being the uſeful part, which however in one or two ſorts is of ſuperior quality; one in particular, the *Rheum Palmatum* of *Linnæus*, is ſuperior to all the others.

[1] RHEUM *Rhaponticum.*

*Rhaponticum, or Common Rhubarb.*] Hath a large, thick, fleſhy, branching, deeply-ſtriking root, yellowiſh within; crowned by very large, roundiſh, heart-ſhaped, ſmooth leaves, on thick, ſlightly-furrowed foot-ſtalks: and an upright, ſtrong ſtem, two or three feet high, adorned with leaves ſingly, and terminated by thick cloſe ſpikes of white flowers.

It grows in Thrace and Scythia, but has been long in the Engliſh gardens; its root affords a gentle purge; is however of inferior quality to ſome of the following ſorts; but the plant being aſtringent, its young ſtalks in ſpring being cut and peeled, are uſed for tarts.

[2]RHEUM *Palmatum.* (Of *Linnæus.*)

*Palmated-leaved True Chineſe Rhubarb.*] Hath a thick fleſhy root, yellow within;

crowned with very large palmated leaves, being deeply divided into acuminated ſegments, expanded like an open hand; upright ſtems, five or ſix feet high or more, terminated by large ſpikes of flowers.

This is now proved to be the true foreign Rhubarb, the purgative quality of which is well known.

3 RHEUM *Compactum.*

*Tartarian Rhubarb.*] Hath a large, fleſhy, branched root, yellow within; crowned by very large heart-ſhaped, ſomewhat lobated, ſharply indented, ſmooth leaves; and an upright large ſtem, five or ſix feet high, garniſhed with leaves ſingly, and branching above; having all the branches terminated by nodding panicles of white flowers.

This has been ſuppoſed to be the true Rhubarb, which however though of ſuperior quality to ſome ſorts, is accounted inferior to the *Rheum Palmatum.*

4 RHEUM *Undulatum.*

*Undulated, or waved-leaved Chineſe Rhubarb.*] Hath a thick, branchy, deep-ſtriking root, yellow within; crowned with large oblong, undulate, ſomewhat hairy leaves, having equal foot-ſtalks, and an upright firm ſtem, four feet high, garniſhed with leaves ſingly, and terminated by long looſe ſpikes of white flowers.

5 RHEUM *Ribes.*

*Arabian Ribes, or Currant Rhubarb of Mount Libanus.*] Hath a thick fleſhy root, very broad leaves, full of granulated protuberances, and with equal foot-ſtalks; and upright firm ſtems, three or four feet, terminated by ſpikes of flowers, ſucceeded by berry-like ſeeds, being ſurrounded by a purple pulp.

All theſe plants are perennial in root, and the leaves and ſtalks are annual; the roots being thick, fleſhy, generally divided, ſtrike deep into the ground; of a browniſh colour without, and yellow within; the leaves riſe in the ſpring, generally come up in a large head folded together, gradually expanding themſelves; having thick foot-ſtalks, and grow from one to two feet or more in length and breadth, ſpreading all round; amidſt them riſe the flower-ſtems, which are garniſhed at each joint by one leaf, and are of ſtrong and expeditious growth, attaining their full height in June, when they flower; and are ſucceeded by large triangular ſeeds, ripening in Auguſt.

Some plants of each ſort merit culture in gardens for variety; they will effect a ſingularity with their luxuriant foliage, ſpikes, and flowers.

And as medical plants, they demand culture both for private and public uſe.

They are propagated by ſeeds ſowed in autumn ſoon after they are ripe, or early in the ſpring, in any open bed of light deep earth; remarking, thoſe intended for medical uſe ſhould generally be ſowed where they are to remain; that the roots being not diſturbed by removal, may grow large; ſcatter the ſeeds thinly, either by broad-caſt all over the ſurface, and raked well in; or in ſhallow drills a foot and half diſtance, covering them near an inch deep. The plants will riſe in the ſpring, but not flower till the ſecond or third year; when they however are come up two or three inches high, thin them to eight or ten inches, and clear out all weeds; though thoſe deſigned always to ſtand, ſhould afterwards be hoed out to a foot and a half or two feet diſtance; obſerving if any are required for the pleaſure ground, &c. for variety, they ſhould be tranſplanted where they are to remain in autumn, when their leaves decay; or early in ſpring before they ſhoot; the others remaining where ſowed, muſt have the ground kept clean between them; and in autumn when the leaves and ſtalks decay, cut them down, and ſlightly dig the ground between the rows of plants, repeating the ſame work every year.

The roots remaining, they encreaſe in ſize annually; and in the ſecond or third year many of them will ſhoot up ſtalks, flower, and perfect ſeeds; and in three or four years the roots will be arrived to a large ſize; though older roots are generally preferable for medical uſe.

RHEXIA, *Rhexia.*

Conſiſts of hardy herbaceous perennials for the pleaſure-ground, riſing with ſtalks a foot high, garniſhed with ſpear-ſhaped leaves, and terminated by tetrapetalous, ſpreading, red flowers.

Claſs and Order, *Octandria Monogynia.*

*Characters.*] CALIX is monophyllous, tubular, ventricoſe below, four parted above, and permanent. COROLLA, four roundiſh patent petals. STAMINA, eight ſlender filaments inſerted in the calix, having declinated linear obtuſe verſatile antheræ. PISTILLUM, a roundiſh germen, ſimple ſtyle, and oblong thick ſtigma. PERICARPIUM, a roundiſh quadrilocular quadrivalved capſule, in the belly of the calix, having numerous roundiſh ſeeds.

There

There are three ſpecies, thoſe of our gardens are the two following: both of America.

[1]RHEXIA *Virginica.*

*Virginia Rhexia.*] Riſes with an erect tetragonous ſtalk above a foot high, garniſhed with ſpear-ſhaped, ſerrated, ſeſſile, oppoſite leaves; and the ſtalks terminated by forked pedunculi, crowned with red flowers, having ſmooth cups.

[2]RHEXIA *Mariana.*

*Maryland Rhexia.*] Riſes with erect ſtalks, ten or twelve inches high; having ſpear-ſhaped, ciliated oppoſite leaves, and the ſtalks terminated by pedunculi, crowned with red flowers.

They both flower in June, but rarely ripen ſeeds here.

Theſe perennials ſucceed here in the open ground all the year, in a dry ſheltered place, though it is proper to keep ſome alſo in pots, to have ſhelter in very ſevere froſts.

They are propagated by ſeed ſowed in autumn, or ſpring, in pots, to be ſheltered from froſt; or if placed on a hot-bed in March, it will forward their growth; and when the plants are two or three inches high, plant them out.

RHODIOLA, Roſe-root.

It is a low, herbaceous, ſucculent, odoriferous perennial, for variety in the pleaſure-ground, having ſucculent leaves and ſtalks, and tetrapetalous dioeceous flowers.

Claſs and Order, *Dioecia Octandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, having monophyllous erect, four-parted, permanent cups. COROLLA, in the males, four oblong obtuſe petals longer than the calix and deciduous; with four erect nectariums, ſhorter than the calix; and in the females, four obtuſe petals, equal with the calix and permanent, with three or four nectariums like the males. STAMINA, eight ſubulate filaments longer than the corolla, having ſimple antheræ. PISTILLUM, four oblong acuminated germens, ſtraight ſimple ſtyles, having obtuſe ſtigmas. PERICARPIUM, four corniculate capſules opening in the inner ſide, and many roundiſh ſeeds.

There is only one ſpecies, grows wild on mountainous parts in England, &c. but has been long a reſident of gardens, viz.

RHODIOLA *Roſea.*

*Rhodiola, or Roſe-root.*] Hath a fleſhy, thick, knotty root, emitting an odour like roſes; ſending up annually erect ſucculent ſtalks, eight or ten inches high, garniſhed with numerous, oblong, thick, ſucculent, ſerrated leaves, alternately; and terminated by cluſters of yellowiſh green flowers.

It flowers in June, and the ſeeds ripen in autumn.

This plant delights in a dry ſoil, and may be planted in any of the common borders, where it will abide for years.

It is propagated both by parting the roots in autumn or ſpring, and by cuttings of the ſtalks, which being cut off early in the ſummer, laid in a room a week to dry the ſucculency of the cut; then plant them in a ſhady border, and if covered cloſe with a hand-glaſs, they will ſtrike in leſs than two months.

RHODODENDRON, Dwarf Roſe-bay.

It compriſes deciduous and evergreen ſhrubs for hardy plantations, garniſhed with lanceolate and oval leaves, and wheel and funnel-ſhaped flowers in cluſters at the ends of the branches.

Claſs and Order, *Decandria Monogynia.*

*Characters.*] CALIX, is five-parted and permanent. COROLLA, is monopetalous, wheel or funnel-ſhaped, five parted, and ſpreading at top. STAMINA, ten declinated filiforme filaments, having oval antheræ. PISTILLUM, a pentagonous retuſe germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, an oval quinquelocular capſule, having numerous ſmall ſeeds.

There are about ſix ſpecies, the principal of which in the Engliſh gardens, are the following deciduous and ever green kinds.

*Deciduous Kinds.*

[1]RHODODENDRON *Ferrugineum.*

*Ferrugeneous Dwarf Roſe-bay of the Alps.*] Riſes with a ſhrubby ſtalk, branching irregularly, three or four feet high; cloſely garniſhed with ſmalliſh ſpear-ſhaped ſmooth leaves, ferrugeneous or iron coloured underneath; and cluſters of funnel-ſhaped red flowers, at the ends of the branches.

[2]RHODODENDRON *Hirſutum.*

*Hairy Dwarf Roſe-bay of the Alps.*] Hath a ſhrubby ſtem, branching numerouſly about two feet high; oval ſpear-ſhaped ciliated, naked leaves, having many iron-coloured hairs underneath, and cluſters of funnel-ſhaped pale-red flowers at the end of the branches.

[3]RHODODENDRON *Chamæciſtus.*

*Chamæciſtus, or Dwarf Roſe bay of Mount Baldis.*] Hath a ſhrubby ſtem, branching numerous and irregularly two or three feet high;

ſmall oval, ſpear-ſhaped, ciliated leaves, and cluſters of wheel-ſhaped flowers at the end of the branches.

*Ever-green Kinds.*

[4]RHODODENDRON *Maximum.*

*Large American Laurel-leaved Rhododendron.*] Riſes with a ſhrubby ſtem, branching eight or ten feet high; large, oval, obtuſe, veined, ſhining, green leaves, the margin acutely reflexed, and pale-red flowers at the ends of branches, each pedunculi having but one flower.

Grows naturally in Virginia.

[5]RHODODENDRON *Ponticum.*

*Pontic Dwarf Roſe-bay.*] Grows four or five feet high, ſpear-ſhaped, ſmooth, ſhining leaves, and the branches terminated by cluſters of bell-ſhaped purple flowers.

It grows naturally in humid places in the Eaſt, and about Gibraltar.

All theſe ſhrubs, both deciduous and ever-green kinds, flower moſtly in June; the flowers are monopetalous, funnel and wheel-ſhaped, in different ſpecies, cut at top into five ſegments; and are ſometimes ſucceeded by ſeed here in England, eſpecially the ſecond, third, and fourth ſorts; the other but ſeldom.

The plants are all of foreign growth, reſidents moſtly of mountainous, rocky, ſhady places; and the laſt generally in moiſt ſituations.

They may all be employed to adorn the ſhrubbery, in which they will appear very ornamental; only they do not thrive ſo well in our gardens as moſt other ſhrubs, unleſs ſtationed in ſoils and ſituations nearly ſimilar to that where they naturally grow.

They are raiſed commonly from ſeeds ſowed in autumn, or as ſoon as they can be obtained, in a ſhady border; the ſeeds being very ſmall, make the ſurface of the ground ſmooth; ſow them thereon evenly, and cover them very lightly with fine mould: they will come up in the ſpring; and after a year's growth, prick them out into a ſhady ſituation.

Their propagation may alſo be tried by layers of the young wood.

RHUS, *Sumach* and *Toxicodendron*, &c.

This genus comprehends many ſpecies of the tree and ſhrub kind, for the ſhrubbery, green-houſe, and ſtove; obtaining from five or ſix, to ten or twelve feet ſtature; garniſhed moſtly with pinnate and trefoliate leaves, and pentapetalous flowers, moſtly in cluſters at the ends and ſides of the branches.

Claſs and Order, *Pentandria Trigynia.*

*Characters.*] CALIX, is monophyllous, five-parted, and permanent. COROLLA, five oval, erect patent petals. STAMINA, five very ſhort filaments and ſmall antheræ. PISTILLUM, a roundiſh germen as large as the corolla; ſcarcely viſible ſtyles, but three ſmall heart-ſhaped ſtigmas. PERICARPIUM, a roundiſh unilocular berry, ſome hairy, others ſmooth in different ſpecies, having a roundiſh hard ſeed.

To this genus is now added the *Toxicodendron*, or Poiſon-tree.

There are of the *Sumachs* and *Toxicodendrons* together, about fifteen ſpecies, all of which are of the tree and ſhrub kind, of foreign growth, of different parts of the world; conſiſting of ſeveral hardy deciduous kinds for the ſhrubbery; ſeveral tenderer ſorts for the green-houſe; and one for the ſtove; the moſt material ſpecies found in the Engliſh gardens, are the following.

*Hardy Sumach deciduous Kind.*

[1]RHUS *Coriaria.*

*Coriaria, or Tanners Sumach.*] Hath a ſtrong woody ſtem, dividing and branching irregularly, ten or twelve feet high; having a browniſh hairy bark; large pinnated leaves, of ſeven or eight pair of oval bluntly-ſawed lobes, terminated by an odd one, and hairy underneath; and large paniculated ſpikes of whitiſh flowers at the ends of the branches.

It grows wild in the ſouth of Europe and in Turky, where the branches are uſed inſtead of oak-bark for tanning leather.

[2]RHUS *Typhinum.*

*Virginian Stag's Horn Sumach.*] Hath a ſhrubby ſtem, branching irregularly eight or ten feet high, having crooked ſpreading branches, dividing into thick ſhoots, covered with a ſoft velvety down, and reſemble the form, colour, and texture of a young ſtag's horn; pinnated leaves of ſix or ſeven pair of ſpear-ſhaped acutely-ſawed lobes, terminated by an odd one, and downy underneath; and at the ends of the branches, large tufts of flowers, ſucceeded by cloſe downy cluſters of purple ſeeds, having a ſingular appearance in autumn and winter.

*Variety.*] Dwarf Virginian Stag's-Horn Sumach.

[3]RHUS

[3]Rhus *Glabrum.*

*Glabrous, or Smooth Sumach.*] Conſiſting of the three following varieties.

*New England Smooth Sumach.*] Riſes with a ſhrubby ſtem, branching irregularly from the bottom and ſides, twelve or fourteen feet high; having ſpreading branches, dividing into very thick, ſomewhat downy, ſmooth, brown ſhoots; large pinnated leaves, of ten or more ſpear-ſhaped lobes, and an odd one, ſmooth on both ſides; and large looſe panicles of greeniſh flowers at the ends of the branches.

*Carolina Smooth Scarlet Sumach.*] Grows eight or ten feet high, with ſmooth purple branches, duſted with a greyiſh powder; long, pinnated, ſmooth leaves like the other, and the branches terminated by large ſcarlet panicles of flowers.

*Canada Smooth Red Sumach.*] Grows eight or ten feet high, having a purpliſh bark, tinged with a whitiſh powder; long pinnated ſmooth leaves, of a ſhining green above, and whitiſh underneath; and the branches terminated by large panicles of red flowers.

[4]Rhus *Copallinum.*

*Copallinum, or Lentiſcus-leaved American Sumach.*] Riſes with a ſhrubby ſtem, dividing into ſpreading, ſmooth, brown branches, four or five feet high; pinnated leaves, of four or five pair of entire lobes, terminated by an odd one; having a membranaceous border running along the foot-ſtalk in joints, and large looſe panicles of greeniſh flowers at the ends of the branches.

*Variety.*] Canada Lentiſcus-leaved Sumach, growing eight or ten feet high, and larger pinnated leaves.

[5]Rhus *Cotinus.*

*Cotinus, Venice Sumach, or Coccygria.*] Riſes with a ſhrubby irregular ſtem, branching widely, about ten feet high, having a ſmooth brown bark; oval, ſimple, ſhining, green leaves; and the branches terminated by long hair-like pedicles, dividing into long hair-like bunches of ſmall purpliſh flowers.

In Italy and Spain, where this ſhrub grows naturally, they uſe the bark for tanning leather.

*Hardy Toxicodendron Deciduous Kinds.*

Theſe are of the ſhrub kind and deciduous, natives moſtly of America; were formerly ranged as a diſtinct genus, *(Toxicodendrum)* but are now made ſpecies of *Rhus*; moſt of the ſorts abounding with a milky poiſonous juice, obtain the appellation of Poiſon-tree in America, where they grow naturally in great abundance.

[6]Rhus *Toxicodendrum.*

*Common American Toxicodendron, or Poiſon-Oak.*] Hath a low ſhrubby ſtem, branching about three feet high, the lower ones trailing and rooting in the ground; ternate or three-lobed leaves, having roundiſh, angulated, and ſometimes entire lobes, each on a ſhort pedicle, and looſe panicles of ſmall whitiſh flowers at the ſides of the branches, ſucceeded by whitiſh berries in autumn.

*Varieties.*] Smooth-leaved—downy leaved—upright-growing.

[7]Rhus *Radicans.*

*Radicant American Toxicodendron.*] Riſes with a ſhrubby ſtem, branching four or five feet high, having trailing, radicant, or rooting branches; ternate ſmooth leaves, with oval entire lobes, and ſhort ſpikes of greeniſh flowers, ſucceeded by roundiſh berries in autumn.

*Variety.*] With upright branches.

[8]Rhus *Vernix.*

*Vernix, or Varniſh Tree, or Pinnated-leaved American Toxicodendron.*] Riſes with a ſtrong woody ſtem, branching thinly on every ſide, eight or ten feet high; pinnated leaves of three or four pair of oblong entire lobes, and an odd one; and at the axillas, looſe panicles of ſmall greeniſh flowers, and roundiſh berries, not ripening here. The milky juice of this tree being remarkable for ſtaining, is ſuppoſed to be the true Varniſh Tree, from which the varniſh is collected.

All the above eight hardy ſpecies being deciduous, produce their leaves in ſpring, and ſhed them in the autumn.

They flower here moſtly in June and July, for the general part in cluſters and panicles; each cluſter compoſed of numerous ſmall pentapetalous flowers, ſucceeded in ſome ſorts by ſeeds, ripening in September.

The plants are all proper furniture for ſhrubberies, wilderneſſes, and other ornamental plantations, to encreaſe the variety of the deciduous collection; they may be planted in any open compartments, in aſſemblage with other hardy deciduous ſhrubs, and they will effect a very agreeable diverſity in ſummer, and ſome ſorts alſo in autumn and winter; particularly ſome of the Sumach kinds, with their ſtag-horn, brown, velvety branches, and their large red panicles.

Obſerve, as ſeveral of the Sumachs abound in ſuckers from the root; and ſome of the *Toxicodendrons* encreaſe exceedingly by their

trailing radicant branches; they ſhould be cleared therefrom every year in winter.

*Method of Propagation.*

They are all eaſily propagated by ſeeds; ſeveral ſorts alſo by ſuckers and their rooting branches; and all the ſorts by layers.

By Seed.—Such ſorts as do not furniſh ſuckers, &c. may be eaſily raiſed from ſeed, procured from abroad; which ſhould be ſowed ſoon after they arrive, either in large pots or in a bed or border of light earth, and covered half an inch deep; they will ſometimes come up in May or June following, though if in pots and plunged in a hot-bed about ſix weeks, it will forward them, being careful to remove them to the full air ſoon after the plants appear; however, as thoſe in the natural earth ſometimes remain till the ſpring after, before they vegetate, keep the ground clear from weeds, give water in dry weather in ſummer, and if a ſevere winter, give occaſional ſhelter of mats, the firſt year; and when the plants are one or two years old, plant them out in nurſery rows, till large enough for the ſhrubbery.

By Suckers.—Several of the Sumachs ſend up abundance from the root; take them up any time in winter, and plant them in nurſery rows for a year or two.

By their radicant Branches.—The two firſt *Toxicodendrons* multiply by their branches, which trail and root in the ground as they advance, which may be taken up in autumn, winter, or ſpring with roots, and they will form proper plants.

By Layers.—Any of the ſorts furniſhing lower branches, may have the young wood laid by ſlit-laying in autumn, and many of them will be rooted in a year.

Moſt of the ſpecies of Rhus abound with a milky juice, reckoned more or leſs poiſonous, particularly the *Toxicodendrons*; as a ſlight touch of the leaves of theſe ſorts cauſe violent itchings, ſometimes followed by an inflammation and ſwelling; and if the juice of the wood or leaves is ſuffered to remain on the ſkin but for a few minutes, it occaſions puſtules like the itch: it is alſo ſaid, the wood of the Poiſon tree when burned, emits a very noxious fume, that will ſuffocate animals expoſed thereto in a room.

*Green houſe Kinds.*

Conſiſts of three African Sumach ſhrubs, comprehending ſeveral varieties; retaining their leaves all the year by ſhelter of the green-houſe in winter, and effect an agreeable variety in that collection.

[9]RHUS *Tomentoſum.*

*Tomentoſe, or Downy African Sumach.*] Hath a ſhrubby ſtem, branching irregularly, ſix or eight feet high; ternate leaves, downy underneath; compoſed of angular, rhomboidal, ſub-petiolated lobes, downy underneath, and ſlender bunches of whitiſh-green flowers from the ſides of the branches.

*Varieties.*] Hairy leaved—Serrated-leaved—Jagged-leaved—Oval-lobed.

[10]RHUS *Anguſtifolium.*

*Narrow-leaved African Sumach.*] Hath a ſhrubby ſtem, and irregular brown branches, growing from five or ſix, to ten or twelve feet high in the varieties; ternate leaves, having linear-lanceolate, entire, petiolated lobes, downy underneath; and ſmall looſe bunches of whitiſh-green flowers from the ſides and ends of the branches.

*Variety.*] Silvery cut-leaved.

[11]RHUS *Lucidum.*

*Lucid, or Shining-leaved African Sumach.*] Hath a ſhrubby ſtrong ſtem, and irregular brown branches, growing ten or twelve feet high; ternate leaves, having wedge-ſhaped, ſeſſile, ſmooth, ſhining-green lobes; and ſmall bunches of greeniſh flowers.

*Varieties*] Round lobed—Heart-ſhaped lobed—Dwarf growing.

Theſe three green-houſe ſpecies muſt be always kept in pots, in order for moving to ſhelter in winter, managing them as other ſhrubby plants of the green-houſe collection. See GREEN-HOUSE PLANTS.

They are eaſily propagated by layers and cuttings.

By Layers.—In ſpring, lay any of the lower young wood in the common way, and they will be rooted and fit to pot off in autumn.

By Cuttings.—Plant cuttings of the young ſhoots in April, May, or June, in pots; and if plunged in any hot-bed, they will ſoon ſtrike, giving occaſional ſhade and watering, and towards autumn pot them off ſeparately.

*Stove Kinds.*

[12]RHUS *Cobbe.*

*Cobbe, or Ceylon Sumach.*] Hath a ſhrubby ſtem, branching eight or ten feet high; ternate leaves, having oval, acuminated, ſawed lobes, and cluſters of whitiſh-green flowers at the ends of the branches, having downy peduncles.

It is a tender exotic, requiring a ſtove in this country, ſo muſt always be kept in pots, and placed in that department and managed as other ſhrubby hot-houſe plants.

Propagate it by cuttings in the ſpring, planted in pots, and plunge them in a bark-bed.

RIBES, Currant-tree and Gooſeberry-buſh.

The Currant and Gooſeberry are hardy deciduous ſhrubs, ſpecies of the ſame genus, each compriſing many varieties, all of buſhy growth; garniſhed with trilobate ſimple leaves, and very ſmall pentapetalous flowers from the ſides of the branches; ſome in racemous cluſters, others ſingly, ſucceeded by globular berries, valuable as early ſummer fruit for the deſert; alſo for various culinary purpoſes, and ſome for medical uſes.

Claſs and Order, *Pentandria Monogynia.*

*Characters.*] CALIX, is monophyllous, ventricoſe, cut into five concave ſegments, and permanent. COROLLA, five ſmall obtuſe petals attached to the border of the calix. STAMINA, five ſubulate filaments inſerted in the calix, having incumbent compreſſed antheræ. PISTILLUM, a roundiſh germen under the flower, bifid ſtyle, and obtuſe ſtigmas. PERICARPIUM, a globoſe, umbilicated, unilocular berry, full of pulp, and many roundiſh compreſſed ſeeds.

The Currant and Gooſeberry were long conſidered each as a ſeparate genus; *Ribes* the Currant, and *Groſſularia* the Gooſeberry; but agreeable to ſyſtematic botany, they are now joined together, the *Groſſularia* being made a ſpecies of *Ribes*; all the Currant kinds having inermous or thornleſs branches, and racemous cluſters of flowers and fruit; and the Gooſeberry have ſpinous branches, and flowers and fruit for the moſt part ſingly.

*Currant Kinds.*

There are three ſpecies of the Currant-tree, two of which and their varieties, merit culture for their fruit; the other as a plant of variety or obſervation; all of which are inermous or unarmed, having no thorns on the branches.

[1]RIBES *Rubrum.*

*Common Red Currant-tree*, &c.] Hath a ſhrubby ſtem, dividing low into many branches, forming a buſhy head, five or ſix feet high, or more, without thorns; broad trilobate leaves, and ſmooth pendulous cluſters of plane greeniſh flowers, ſucceeded by cluſters of ſmall berries.

It grows naturally in woods and hedges in England, and moſt parts of Europe.

*Varieties.*] Compriſes all the ſorts of Red and White Currants, as, Common, ſmall, Red Currant——Large Red Dutch Currant—Long bunched Red Currant—Champaigne Pale-red Currant—Common ſmall White Currant—Large White Dutch Currnt—Yellow blotched leaved Currant—Silver ſtriped-leaved—Gold ſtriped-leaved—Gooſeberry-leaved.

All theſe ſorts are varieties of one ſpecies: *Ribes Rubrum*, or *Common Red Currant*, it being the parent from which all the others were firſt obtained from the ſeed, and improved by culture; they all flower in the ſpring, and the fruit ripens in June and July; and by having the trees in different ſituations and modes of training, ſuch as plantations of ſtandards in the open quarters, for the general ſupply, others trained againſt walls or pales, of different aſpect, the fruit may be continued ripe in good perfection, from about the middle of June until November, provided the later crops are defended with mats or nets from the birds: the ripe fruit of all the varieties are valuable, not only to eat raw, as being of an agreeable, quick, acid reliſh, and fine cooling quality, excellent to quench thirſt and create an appetite; but the red ſorts in particular are made into gellies, tarts, ſauces, and other culinary preparations. Likewiſe, of Currants is made good wine, and they are alſo uſed in medicine; ſo that plenty of the trees ſhould be cultivated in every garden for the fruit, both for private uſe and the ſupply of markets: as to the variegated-leaved kinds, they are valued as furniture for the ſhrubbery, to cauſe diverſity in the different variegations of their leaves; they alſo bear fruit plentifully like the other kinds; and all the varieties of every ſort are very eaſy of propagation and culture, by cuttings, ſuckers, and layers. See their *Propagation.*

[2]RIBES *Nigrum.*

*Black Currant-tree.*] Hath a ſhrubby ſtem, dividing low into many branches, forming a buſhy head, five or ſix feet high; broad trilobate leaves of a rank odour, and having racemous cluſters of oblong greeniſh flowers, ſucceeded by thin cluſters of black-berries.

The fruit of this ſpecies being of a ſtrong flavour and ſomewhat phyſical reliſh, is not generally liked; it however is accounted very wholeſome, and of which is alſo made a ſyrup of high eſtimation for ſore throats and quinſeys; hence the fruit is often called ſquinancy berries

*Vari-*

*Variety.*] *Penſylvanian Black Currant.* Having ſmaller ſhoots and leaves; not ſtrong ſcented, and ſmall fruit of but little value; ſo the ſhrub is eſteemed only for variety in ſhrubberies.

The mode of bearing of all the varieties of Currants, is both on the old and young wood, all along the ſides of the branches and ſhoots, often upon a ſort of ſmall ſpurs and ſnags, producing the fruit in numerous long pendulous cluſters.

*Groſſularia, or Gooſeberry Kinds.*

Of the *Groſſularia* or Gooſeberry kinds, there are four or five ſpecies, comprehending many varieties, all of which are of buſhy growth, from about three or four, to ſix or ſeven feet high; ſome being upright, others of reclinated growth; have all their branches armed with ſpines, and produce their fruit both on the young and old wood, all along the ſides of the branches and ſhoots; ſometimes immediately from the eyes or buds, of the young wood in particular, and alſo on ſmall ſpurs on the older branches; in all of which the flowers and fruit ariſe, ſome ſingly, others in ſmall bunches; all of the berry kind; uſeful both when green and ripe; green, for tarts, pies, ſauces, and for preſerving in bottles for winter uſe; and when ripe, it is valuable as an early deſert fruit; and the different ſorts afford great variety at table, in their different colours and reliſhes.

[3]Ribes *Groſſularia.*

*Groſſularia, or Common Gooſeberry-buſh.*] Riſes with a low ſhrubby ſtem, dividing low into a very branchy buſhy head, armed with ſpines; trilobate ſmalliſh leaves, having hairy ciliated foot-ſtalks, and ſmall greeniſh flowers, ſucceeded by hairy berries.

*Varieties* ] Conſiſts of many varieties of different ſizes and colours, as hereafter deſcribed.

[4]Ribes *Reclinatum.*

*Reclinated broad-leaved Gooſeberry-buſh.*] Riſes with a low ſhrubby ſtem, and reclinated ſomewhat prickly branches; trilobate broadiſh leaves, and ſmall greeniſh flowers, having the pedunculi furniſhed with triphyllous bractea.

[5]Ribes *Oxyacanthoides.*

*Oxyacantha-leaved Gooſeberry.*] Hath a ſhrubby ſtem, and branches armed on all ſides with ſpines; and largiſh trilobate hawthorn leaves.

[6]Ribes *Uva criſpa.*

*Uva criſpa, or Smooth Gooſeberry.*] Hath a ſhrubby ſtem and branches, armed with ſpines; trilobate leaves; pedicles having monophyllous bractea; and ſmooth fruit.

[7]Ribes *Cynoſbati.*

*Prickly-fruited Gooſeberry-buſh.*] Hath a ſhrubby ſtem and branches armed with ſpines moſtly at the axillas; and prickly fruit in cluſters.

*Varieties of the different ſpecies.*] Many varieties of Gooſeberries have been raiſed from ſeeds; ſome having round berries, others oval; ſome hairy and ſome ſmooth, and of different colours, as Red—Green—Yellow—White, &c. conſiſting of the following varieties of each ſort

*Red Kinds.*—Hairy Red Gooſeberry—Smooth Red Gooſeberry—Deep Red Gooſeberry—Damſon, or Dark-red blueiſh Gooſeberry—Red Raſpberry Gooſeberry—Early Black-red Gooſeberry.

*Green Kinds.*—Hairy Green Gooſeberry—Smooth Green Gooſeberry—Green Gaſcoigne Gooſeberry—Green Raſpberry Gooſeberry.

*Yellow Kinds.*—Great oval Yellow Gooſeberry—Great Amber Gooſeberry—Hairy Amber Gooſeberry—Early Amber Gooſeberry.

*White Kinds.*—Large White Cryſtal Gooſeberry—Common White Gooſeberry—White-veined Gooſeberry.

*Other Varieties of different Sorts.*] Champaigne Gooſeberry—Rumbullion Gooſeberry—Large Ironmonger Gooſeberry—Smooth Ironmonger Gooſeberry—Hairy Globe Gooſeberry—Large Tawney, or Great Mogul Gooſeberry.

All the above ſeven ſpecies of *Ribes*, both Currant and Gooſeberry kinds and their reſpective varieties, are very hardy ſhrubs, that proſper almoſt any where, both in open and ſhady ſituations, and in any common ſoil; bearing plentifully in any expoſure, though in open ſunny ſituations, they produce the largeſt and faireſt fruit, ripening to a richer vinous flavour; but it is eligible to plant them in different ſituations and aſpects, in order to have the fruit as early and late as poſſible.

They are commonly planted in the kitchen garden moſtly as dwarf ſtandards, in the open quarters, for the general ſupply; being diſpoſed ſometimes in continued plantations in rows, eight or ten feet by ſix aſunder, where great quantities of the fruit are required for market or other large ſupplies; and are ſometimes diſpoſed in ſingle ranges round the outward edge of the quarters, eight feet aſunder; frequently in ſingle croſs rows, in order to divide the ground into ſeparate wide plats or breaks, of

of from twenty to thirty or forty feet width; which alſo ſerves to ſhelter the ground a little in winter; in all of which methods of planting them as ſtandards, they ſhould be generally trained up to a ſingle ſtem about a foot high, then ſuffered to branch out every way all around into buſhy heads, keeping the middle however open, and the branches moderately thin, to admit the ſun and free air; though if ſome are fanned, that is, trimmed on two ſides oppoſitely, ſo as to make the other branches range in a line like an eſpalier, whereby they will take up much leſs of the ground, and, by admitting the ſun and air more freely, they will produce large fair fruit.

They are likewiſe trained againſt walls or palings, like other wall trees; but principally ſome of the large red and white Dutch Currants, in which they will produce fine large fruit, and thoſe againſt any ſouth fence will ripen early and be high flavoured; but it is proper to plant a few both againſt ſouth, north, eaſt, and weſt walls, in order to obtain the fruit ripening both early and late, in a long ſucceſſion. It is alſo proper to plant a few of the fineſt ſorts of Gooſeberries againſt a warm fence, both to have early green Gooſeberries for tarts, &c. as well as to ripen early; and they will grow very large and fine.

Sometimes both Currants and Gooſeberries are alſo trained in low eſpaliers for variety, and they produce very fine fruit.

All the varieties of theſe ſhrubs are raiſed plentifully in the nurſeries for ſale.

*Method of Propagation.*

All the ſorts of Currants and Gooſeberries are expeditiouſly propagated by cuttings, ſuckers, and layers; but as every cutting and ſlip will moſt readily grow, that mode of propagating them is moſt commonly adopted in the nurſeries, in raiſing great quantities for ſale.

By Cuttings. — Autumn, at the fall of the leaf, is the moſt eligible ſeaſon for planting the cuttings; it may alſo be performed any time in winter, in open weather, and early part of the ſpring; chuſing the young ſhoots of laſt ſummer, cutting them off from about ten or twelve to eighten inches long, and plant them in any ſhady border, in rows a foot aſunder, each full half way into the ground; they will root firmly the enſuing ſummer, ſhoot at top, and form tolerable little plants by next autumn, when every other row may be thinned out, and planted in nurſery lines two feet and half aſunder; afterwards train the whole for the purpoſes deſigned.

Obſerve thoſe deſigned for common ſtandards, ſhould be trained up to a twelve or ſifteen inch ſtem, then encourage them to branch out all around at that height to form a full head; for if ſuffered to branch away immediately from the bottom, according to the natural mode of growth of theſe kind of trees, as is often the caſe in many gardens, they overſpread the ground, that no crops can grow near them, as well as appear unſightly, and render it inconvenient to do the neceſſary work: it is therefore of importance to keep them to a ſingle ſtem, a foot at leaſt high, then ſuffered to form the firſt ſet of branches, trimming off low ſtragglers, and encourage the more upright growths; thinning them to moderate diſtances, and reduce long ramblers to preſerve a ſomewhat regular head; the trees will thus aſſume a decent appearance, admit of ſmall crops under them, and will be more eaſily kept in regular order.

And if intended to train any of them with fanned branches, either for fanned ſtandards, or for walls and eſpaliers, they muſt be encouraged to branch out near the bottom, and ranged the way of the rows, cutting off all croſs or foreright ſhoots, ſo as to form the branches in a ſtraight range, like an eſpalier, &c.

In all the above modes of training theſe ſhrubs, by cuttings, they will attain a bearing ſtate in two or three years.

By Suckers.—All the ſorts ſend up ſuckers very plenteouſly from the roots, each ſucker forming a proper plant, and is the moſt expeditious mode of propagating all the varieties, both Currants and Gooſeberries; they may be taken up in autumn, winter, or ſpring, with roots, or even ſuch as are without fibres will ſucceed; for the lower part having been ſituated in the ground, is naturally diſpoſed to ſend out fibres very ſoon; planting them either in nurſery rows for a year or two, or ſuch as are tall and ſtrong may be planted at once where they are to remain: obſerving to train the whole for the purpoſes intended, as directed for the cuttings, and they will form bearing plants after one or two years growth.

But the propagating them by ſuckers, is by ſome objected to, as alledging they incline to run greatly to ſuckers again, and encumber the ground; there is however, but little foundation in this, for it is peculiar to theſe ſhrubs,

them be raiſed either by ſeeds, cuttings, or any other method, they are natrually diſpoſed to ſend up many ſuckers from the roots annually. See SUCKERS.

Sometimes theſe ſhrubs having been permitted to advance with ſeveral ſtems, formed by ſuckers that have ariſen directly from the root; the whole forming a large ſpreading buſh; which, if taken up may be divided into ſeveral ſeparate plants, with good roots and branchy heads, and planted out finally to remain; they will at once commence good bearing plants, producing fruit the following ſummer.

By Layers.—The young branches being laid any how, in autumn, winter, or ſpring, will readily ſtrike root, and next autumn be fit to tranſplant.

In the general propagation of theſe ſhrubs, we would obſerve, that, as they naturally throw out many ſuckers from the root, ſo as often to become troubleſome, it is proper, previous to planting the cuttings, and ſuckers, &c. to rub off cloſe all the buds or prominent eyes, from the lower part, as far as they are to be put into the ground, which will in ſome meaſure diminiſh their tendency in the production of ſuckers: likewiſe, when tranſplanting the young plants, if they diſcover any tendency to the bottom for ſuckers, let all ſuch parts be alſo carefully rubbed off cloſe.

*Final Tranſplantation.*

When theſe ſhrubs are grown about two or three feet high, having tolerable heads, they are of a proper ſize for tranſplanting finally, into the garden where they are to remain for bearing.

They may be tranſplanted any time from October until March, in open weather.

Plant them in rows, eight or ten feet diſtance, both as ſtandards and for walls, &c. obſerving to plant the principal quantity as ſtandards for the general ſupply, and a few of the choicer ſorts for walls, particularly of the Currants.

In planting them for ſtandards, if a full or continued plantation of them is intended, ſet them in rows eight or ten feet aſunder, as above obſerved; and ſix diſtant in the ranges; and if deſigned in ſingle rows, either round or croſs ways the quarters, allow full ſeven or eight feet diſtance, for if cloſer, they will ſoon meet and prove troubleſome.

And in planting them againſt walls or eſpaliers, let ſome be planted againſt a ſouth wall, to produce early fruit; others on a north; and other aſpected fences; allowing them eight or ten feet diſtance, as aforeſaid, and train their branches four or five inches aſunder.

*General Culture.*

*Their culture in common Standards.*—Continue to train them with a ſingle ſtem, a foot high, as already hinted; and let the head branch out four or five feet high, keeping the middle ſomewhat hollow, and the branches at tolerable diſtances, by occaſional pruning, not with garden ſheers, but regularly with a pruning knife; obſerving however, if the plants are permitted to aſpire in in height, ſhoot at full length, and take their own natural growth, they will grow higher and more ſpreading, and ſhoot more moderate, than if pruned annually, and will alſo bear plentifully without trouble; though if they are kept down by proper pruning, to about four feet height, the middle kept open, and the branches thin, at ſome reaſonable diſtances, they will probably produce larger fruit, ripening ſooner, and with a better flavour; but remarking, in this caſe, that by the annual pruning to keep the ſhrubs low and regular, it cauſes them to throw out numerous ſhoots every ſummer, and crowd them with uſeleſs wood, which muſt be regulated accordingly, by pruning them every winter, to retrench all that are evidently ſuperfluous, and reſerving others occaſioally in proper places for young bearers, and to cut out irregular crowding branches occaſionally.

This pruning is performed in winter, or any time from the fall of the leaf till February. With your knife retrench all ſuperfluous ſhoots of laſt ſummer from the middle of the plants, and from the ſides of the branches in general, only reſerving a terminating ſhoot to every branch, and ſome regular ſhoots occaſionally towards the lower parts, either to be coming forward for young bearers, or to fill any preſent or apparently future vacancy; or to ſupply the place of any worn out branches, or dead wood, which ſhould always be retrenched, and ſome contiguous ſhoots retained in its ſtead, and clear the bottom from all ſuckers, &c.

At the ſame time obſerving, that when the branches in general become too numerous and crowding, or grow acroſs, or in any very irregular growth, to cauſe confuſion and diſorder, they ſhould alſo be regulated by pruning out the moſt irregular, leaving the others five or ſix inches aſunder; likewiſe, retrench all low ſtragglers; and according as any of the branches

branches become too long, or advanced higher than you intend, or any long rambler happening, they ſhould be reduced to order, by ſhortening them down to ſome convenient young ſhoot, or lower young branch terminated by one; for in reducing or ſhortening the branches, as occaſion may require, they ſhould not be ſtumped off, but pruned down to a young ſhoot or branch; as juſt hinted; that they may ſtill terminate in a young ſhoot for a leader.

The general ſupply of young ſhoots may be more or leſs ſhortened, according to their ſtrength and ſituation, but more particularly the currants, if thought neceſſary to keep the head low and within ſmall compaſs; cutting the upper ſhoots to ſix, eight, or ten inches; but the lower ones deſigned to grow up to fill any vacancy, leave longer in proportion, or at full length, as it ſhall ſeem proper, till arrived to the deſired height.

But the Gooſeberry kinds having the young wood much ſhortened, it cauſes them to throw out very numerous ſhoots in ſummer, and crowd the buſhes exceedingly with unneceſſary wood, it is therefore eligible to ſhorten the ſhoots of theſe kinds but moderately, or leave them moſtly entire, or at full length; ſuch however, as recline conſiderably, or ramble away from all the reſt, ſhould be reduced with the knife, ſo as to preſerve a little regularity in the head.

To conclude, be careful always, both in the Currant and Gooſeberry kinds, not to ſuffer them to become of ſtraggling growth, ſpreading near the ground, nor too much crowded at top; but annually clear off all ſuckers from the bottom, all lower ſtraggling ſhoots from the ſtem, and keep the middle of the head open, and the branches in general thin, about ſix or ſeven inches aſunder, as aforeſaid, preſerving all the ſmall laterals bearing ſnags, natural ſpurs and fruit-buds; and thus theſe ſhrubs will always bear large and fair fruit in great abundance.

*Their culture in fanned Standards.*—If intended to fan any of them in ſtandards, ranging the branches in the manner of eſpaliers, you muſt encourage only the branches that range the way of the rows, trimming off all fore and back ſhoots, and range the others about ſix inches aſunder, at full length, till thoſe of each tree nearly approach, giving occaſional pruning both in ſummer to retrench all ſuperfluous and projecting foreright ſhoots; and in winter to give a general regulation as obſerved for the common buſh ſtandards.

*Training them againſt walls and eſpaliers.*—Let them branch out near the bottom, as formerly noticed in the nurſery culture, clearing off all foreright growers, and train the others horizontally to the wall, &c. five or ſix inches aſunder, at full length, till they have filled the allotted ſpace; they will naturally form fruit-buds all along their ſides, and bear abundantly. Obſerve to give them a ſummer and a winter pruning; in ſummer to retrench cloſe all foreright, and evidently ſuperfluous ſhoots, and train in only an occaſional ſupply of ſome of the moſt regular ſhoots towards the lower parts till winter, in caſe of a vacancy, or to be in training for young bearers; and if then not wanted, muſt be diſplaced; and by this regulation in ſummer, it not only preſerves the uniformity of the trees, but exhibits the fruit to view, and gives acceſs to a due portion of ſun and air to improve its growth and flavour. And in winter pruning, ſee if there are any vacancies, and retain ſome contiguous ſhoot left in ſummer, cutting out any worn out or naked branch, down to ſome lower ſhoot or young branch, as obſerved of the ſtandard buſhes; looking occaſionally to the lower part of the trees for any well placed ſtrong ſhoots, and ſee if they are wanted either to fill a preſent vacancy, or for training in to ſerve future purpoſes to ſupply the place of any old branch becoming naked, or unfurniſhed with bearing parts; in which caſes, retain occaſional ſupplies of young wood as you ſhall ſee neceſſary, keep all the main branches at regular diſtances, preſerving all the ſpurs and fruit-buds, but cut off any long projecting ſnags, and all dead wood. Then train the whole ſtraight and cloſe to the wall at the diſtances afore-mentioned.

Theſe trees thus properly trained againſt walls, will grow eight or ten feet high, and extended widely every way.

### *Of the Fruit.*

The fruit of all the varieties, both Currants and Gooſeberries, on ſtandards and againſt walls, begin to ripen in June, but do not attain full perfection till July; thoſe againſt warm walls ripen ſooneſt by a fortnight, if the trees are properly dreſſed in ſummer, and will be ſucceeded by the ſtandards for the general crop.

When deſigned to continue a ſupply of theſe fruit, as long in the ſeaſon as poſſible, it is proper to net ſome of the fulleſt trees, when they begin to ripen, to defend the berries from the birds; and mat others to ſhade them from the

ſun, in order to retard their ripening. And if when full ripe, ſome are cloſely matted with large mats, particularly Currants, it will preſerve the fruit in perfection on the trees till October or November.

RICINUS, *Palma Chriſti.*

Conſiſts of tall, herbaceous, tender annuals for the pleaſure ground, riſing with ſtrong erect ſtems from three or four to ten or twelve feet high, adorned with luxuriant, palmated, peltated leaves, on long foot-ſtalks, and long ſpikes of apetalous monoeceous flowers, in July and Auguſt.

Claſs and order, *Monoecia, Monadelphia.*

*Characters.*] CALIX, male and female flowers, apart in the ſame ſpike; the males having monophyllous, five-parted cups, and thoſe of the females three-parted, and deciduous.——COROLLA, no petals.—STAMINA, numerous filiforme filaments, variouſly connected in the monadelphous way, terminated by roundiſh didymous antheræ.—PISTILLUM, an oval covered germen, three bifid, erect-patent ſtyles, crowned by ſimple ſtigmas.—PERICARPIUM, a roundiſh triſulcated, trivalved, trilocular capſule, each cell having a ſingle oval ſeed.

There are three ſpecies, one of which only is common to our gardens, comprehending ſeveral varieties, ſome growing eight or ten feet high, others not above half ſo much, eſteemed as ornamental plants for the ſingularity of their large, beautiful leaves, from one to two feet and half broad, deeply lobated into ſix or ſeven ſegments, expanded in the palmated way, and the foot-ſtalks, fixed in the middle underneath, in the peltated manner. See FOLIUM.

The ſpecies is

RICINUS *Communis.*

*Common Palma Chriſti.*] Riſes with an upright, ſtrong, herbaceous, jointed ſtem, eight or ten feet high; having ſub-palmated, peltated ſawed leaves, and at the axillas, long ſpikes of whitiſh-green flowers, ſucceeded by ripe ſeeds in autumn.

*Varieties.*] There are many varieties, formerly ſuppoſed to be diſtinct ſpecies, but are found to be all varieties only of *Ricinus Communis* — and of which there are — *Major Palma Chriſti*, growing from about ſix or eight to ten or twelve feet high. — *Minor Palma Chriſti*, growing but three or four feet high — green-ſtalked — grey-ſtalked—brown-ſtalked—red-ſtalked, &c.—broad-leaved, being more than two feet in breadth — leſſer-leaved, being from ten or twelve to fifteen or eighteen inches wide—deeply divided-leaved—ſlightly divided-leaved—grey-leaved—green-leaved—ſix-lobed-leaved — ſeven-lobed-leaved, &c. being all varieties of one ſpecies, which, and its varieties in general, are annual or biennial, natives of Africa, America, and the South of Europe, and require a hot-bed to raiſe them in this country.

They are fine majeſtic plants, annual, or at moſt biennial in England; but in their native ſoil, it is ſaid, they are durable both in root and ſtem. In England however, we conſider them only as annuals, for being raiſed from ſeed in the ſpring, they ſhoot up to ſtem, flower, and perfect ſeeds the ſame year, and, if not ſheltered, die root and all in the winter: but being ſheltered in a green houſe, or ſtove, during that ſeaſon they will abide two years.

Their merit in our gardens is as ornamental plants, being raiſed firſt in a hot-bed, then tranſplanted into the borders in ſummer, they will effect a fine variety.

*Their Propagation, &c.*

They are raiſed from ſeed ſowed in any hot-bed with other tenderiſh annuals, ſuch as Africans, China aſters, &c. half an inch deep: when they are come up three inches high, pot ſome of them ſeparately in ſmall pots, which plunge alſo in a hot bed; others prick in the earth of the bed, giving plenty of water, and according as they encreaſe in ſize, ſhift thoſe in pots into larger ſizes; and about the end of May, or beginning of June, remove all of them into the full air, tranſplanting ſome with balls about their roots into the open borders, and retain ſome in pots to move occaſionally, where wanted: ſupplying the whole with water in dry weather, particularly the tranſplanted plants in the borders, &c. till firmly rooted, and the potted plants all the ſummer, about three times a week. Thus theſe fine plants will grow to their full height in Auguſt, well cloathed with their noble foliage, and will produce flowers and ſeed.

If intended to preſerve any in the greenhouſe all the winter for variety, chuſe ſome of the handſomeſt potted plants, which remove into that repoſitory in October, where they will retain their ſtems and leaves.

RIDGING *Ground.*——See DIGGING *by Trenches*, and TRENCHING.

RIVINIA, *Rivinia.*

Two ſhrubby ever-greens for the ſtove compoſe this genus: one a low upright plant, the other a high climber; furniſhed with heart-

ſhaped

ſhaped and oval leaves, and ſpikes of ſmall apetalous flowers.

Claſs and order, *Tetandria Monogynia.*

*Characters.*] CALIX, four oblong-oval, coloured, permanent leaves.——COROLLA, no petals.——STAMINA, four and ſome eight permanent filaments, having ſmall antheræ.—PISTILLUM, a large roundiſh germen, ſhort ſtyle, and obtuſe ſtigma.—PERICARPIUM, a globular unilocular berry lodged cloſe in the calix, having one roundiſh ſeed.

The ſpecies are.

[1]RIVINIA *Humilis.*

*Dwarf Tetrandrous Jamaica Rivinia.*] Hath a low ſhrubby ſtem, dividing and branching three or four feet high; heart-ſhaped leaves, and long ſpikes of ſmall tetrandrous flowers, ſucceeded by red berries.

*Varieties.*] Downy-leaved — white-flowered — ſcarlet-flowered.

[2]RIVINIA *Octandria.*

*Climbing Octandrous American Rivinia.*] Riſes with a ſhrubby, climbing, branchy ſtem, fifteen or eighteen feet high. Oval ſpear-ſhaped leaves, and looſe ſpikes of ſmall octandrous flowers, ſucceeded by blue berries.

Both the ſpecies are ever-green, and being tender exotics from the warmeſt parts of America, muſt be kept always in pots, and placed among the ſtove plants, where they will flower moſt times of the year: the flowers are apetalous, ſeparately ſmall, but numerous in each ſpike, ariſing in great abundance from the ſides and ends of the branches, ſucceeded by berries.

They are raiſed from ſeed ſowed in pots, and plunged in a bark-bed. Try them alſo by layers and cuttings, aſſiſted by heat.

ROBINIA, Falſe Acacia.

Conſiſts of hardy deciduous trees and ſhrubs for ornamental plantations, and tender kinds for the hot-houſe collection; adorned with pinnated and quaternate leaves; and pendulous cluſters of papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is monophyllous, and four-parted, having the three under-ſegments narrow, the other broad.—COROLLA, is papilionaceous, having a large round patent vexillum, two oval wings, with ſhort appendices, and a nearly ſemi-orbicular depreſſed carina.—STAMINA, ten diadelphous filaments, and roundiſh antheræ.—PISTILLUM, a cylindric oblong germen, ſlender bent ſtyle, and hairy ſtigma.—PERICARPIUM, a large oblong compreſſed pod, having kindney-ſhaped ſeeds.

There are ſix ſpecies, all of the tree and ſhrub kind, four of them hardy for the ſhrubbery, and two tender for the ſtove.

*Hardy Kinds.*

Theſe conſiſt of one large tree, and three moderate ſhrubs, all deciduous, natives of foreign parts, America, Siberia, and Tartary, but all hardy enough to ſucceed in our open plantations.

[1]ROBINIA, *Pſeud Acacia.*

*Common Pſeud-Acacia, Falſe-Acacia, or American Robinia.*] Riſes with a ſtrong, woody trunk, dividing and branching thirty or forty feet high; armed with ſtrong ſpines; large, long, pinnated leaves of nine or ten pair of oval lobes, and an odd one, having prickly ſtipulæ, and long pendulous racemous cluſters of papilionaceous, white, odoriferous flowers, one on each pedicle, ſucceeded by ſmooth ſeed-pods.

*Varieties.*] Conſiſts of the two following, formerly conſidered as diſtinct ſpecies, viz.

*Echinated, or Prickly-podded American Falſe-Acacia.*] Grows thirty or forty feet high, having leaves and flowers like the other, but ſhort very prickly pods.

*Roſe Acacia, or Hiſpid American Robinia.*] Grows fifteen or twenty feet high, but appears like a moderate ſhrub in England, armed with ſpines, and hiſpid hairs on every part, having leaves and flowers formed like the other: but the flowers are of a beautiful roſe-colour, making a fine appearance.

This is a very beautiful flowering ſhrub, for the principal compartments of the ſhrubbery.

[2]ROBINIA, *Caragana.*

*Caragana, or Siberian Robinia.*] Riſes with a ſhrubby ſtem, branching eight or ten feet high, or more: abruptly pinnated leaves of five or ſix pair of oval lobes, not terminated by an odd one; and ſimple or unbranched pedunculi, ſuſtaining ſmall yellow flowers.

[3]ROBINIA *Fruteſcens.*

*Shrubby Quaternate-leaved Siberian Robinia.*] Hath a ſhrubby ſtem, branching ſix or eight feet high, quaternate oval leaves, on ſhort foot-ſtalks: and ſimple pedunculi, ſuſtaining yellow-flowers.

[4]ROBINIA, *Pigmæa.*

*Dwarf quaternate leaved Siberian Robinia.*] Hath a low ſhrubby ſtem, branching about three feet high. Quaternate, wedge-ſhaped, cloſe-ſitting leaves; and ſimple pedunculi, ſuſtaining yellow-flowers.

The above four hardy ſpecies flower here annually, the firſt ſort in June, and the others in May. The flowers are all papilionaceous and

and tetrapetalous; ariſing from the ſides and ends of the branches; which in the firſt ſort and varieties being produced in long cluſters, make a fine appearance, particularly the variety *Roſe Acacia*; and moſt of the ſorts are ſucceeded by ſeed-pods, ripening in September, particularly the laſt three ſpecies.

They are all proper furniture for embelliſhing the ſhrubberies, will ſucceed any where, and exhibit a fine variety with their pinnated and quaternate leaves, and the *Pſeud-Acacia*, and varieties, alſo with the numerous cluſters of flowers.

*Hot-houſe Kinds.*

Conſiſts of two tree and ſhrub ſpecies, natives of the warm parts of America and India.

[5]ROBINIA *Violacea.*

*Violet American Robinia.*] Hath a woody trunk, branching twenty feet high: pinnated leaves of eight or ten pair of oval lobes, and an odd one: and cluſters of violet coloured-flowers, two on each pedicle.

*Varieties.*] With dark-blue-flowers—ſcarlet-flowered — and with leaves having ſpear-ſhaped lobes — oblong lobes, &c.

[6]ROBINIA *Mitis.*

*Smooth Indian Robinia.*] Hath a ſmooth ſhrubby-ſtem, and taper branches; pinnated leaves, of ſeveral pair of oval lobes, and an odd one; and cluſters of whitiſh flowers, three on each pedicle.

All the four hardy ſpecies being for the ſhrubbery, may be had at the nurſeries, particularly the firſt ſort and varieties, and the *Caragana*: and may all be planted in any common ſoil and ſituation.

But the two tender ſpecies muſt always be kept in pots, and placed in the ſtove.

*Method of Propagation.*

The hardy kinds are raiſed from ſeeds, cuttings, layers, and ſuckers.

By Seeds.—In March, ſow them in any bed of light mould, half an inch deep: the plants will come up in leſs then two months, the firſt ſpecies and varieties in particular, the others ſometimes not till ſpring after, unleſs ſowed in autumn: give occaſional weeding and watering, and in the ſpring following plant them out in nurſery rows, to have two or three years growth.

By Cuttings.—In October or November, having a quantity of cuttings of the young ſhoots, plant them in a ſhady border, and they will be rooted well in one year.

By Layers.—Lay the young wood in autumn, they will be rooted by autumn following.

By Suckers.—The firſt ſpecies generally ſend up plenty from the root, which tranſplant any time from October till March.

The tender ſorts are raiſed from ſeed cuttings and layers, aſſiſted by artificial heat.

ROSA, Roſe-Tree.

This noted genus comprehends numerous deciduous flowering ſhrubs, and an evergreen; all of hardy growth, and the pride of the ſhrubby-flowering tribe, for adorning the pleaſure-grounds, &c. with their large elegant flowers, in great profuſion, for ſeveral months in ſummer; are garniſhed with pinnated rough leaves, of from three to five or ſeven lobes; and numerous large pentapetalous, very odoriferous flowers, compriſing many double varieties of ſingular beauty.

Claſs and order, *Icoſandria Polygynia.*

*Characters.*] CALIX is monophyllous, ventricoſe, and fleſhy below, and divided at top into five long, narrow, ſpear-ſhaped ſegments, two of which alternately, having appendices on their ſides, two alternately naked, and the fifth ſometimes appendiculated on one ſide only.—COROLLA, five obverſely heart-ſhaped petals, inſerted into the calix.—STAMINA, numerous ſhort capillary filaments, inſerted into the neck of the calix, and trigonous antheræ.—PISTILLUM, numerous germina in the bottom of the calix, and numerous very ſhort hairy ſtyles, ſtraitly compreſſed in the neck of the calix, and inſerted into the ſides of the germen, crowned by obtuſe ſtigmas.—PERICARPIUM, the fleſhy baſe of the calix becomes a turbinated, fleſhy, ſoft, unilocular berry, having numerous oblong hairy ſeeds, faſtened on each ſide to the calix.

The ſorts of Roſes are very numerous, and the botaniſts find it very difficult to determine, with accuracy, which are ſpecies, and which varieties, as well as which are varieties of the reſpective ſpecies, on which account Linnæus, and ſome other eminent authors, are inclined to think that there is only one real ſpecies of Roſe, which is the *Roſa Canina*, or Dog-Roſe of the hedges, &c. and that all the other ſorts are accidental varieties of it; however, according to the preſent Linnæan arrangement, they ſtand divided into fourteen ſuppoſed ſpecies, each deſcribed to have ſome particular mark of diſtinction, though in ſeveral ſorts, is not very conſpicuous, and agreeable to the

ſpecific

ſpecifie deſcription of the ſeveral ſpecies, each comprehends ſome varieties, which, in ſome ſorts are but few, others numerous.

The ſuppoſed ſpecies, and their varieties, according to the arrangement of modern botaniſts, are as follow:

[1]ROSA *Canina.*

*Canine Roſe, or Wild Dog-Roſe of the Hedges, or Hep-tree.*] Grows five or ſix feet high, having prickly-ſtalks and branches, pinnated, five or ſeven-lobed leaves, with aculeated foot-ſtalks; ſmooth pedunculi; oval, ſmooth germina, and ſmall ſingle-flowers.

*Varieties.*] Red-flowered canine Roſe—white-flowered.

They grow wild in hedges abundantly all over the kingdom: and are ſometimes admitted into gardens, a few to increaſe the variety of the ſhrubbery collection.

[2]ROSA *Alba.*

*Common White-Roſe.*] Grows five or ſix feet high, having a green ſtem and branches, armed with prickles; hiſpid pedunculi; oval ſmooth germina, and large white flowers.

*Varieties.*] Large double White Roſe—ſemi-double White Roſe—dwarf ſingle White Roſe—maidens-bluſh White Roſe, being large, produced in cluſters, and of a white and bluſh red colour.

[3]ROSA *Gallica.*

*Gallican Roſe, &c.*] Grows from about three or four to eight or ten feet high, in different varieties, pinnated three, five, or ſeven lobed leaves, and large red, and other coloured-flowers in different ſorts.

The ſpecific deſcription is.——Roſe, with hiſpid, prickly branches, and petioles; hiſpid pedunculi, and oval hiſpid germina.

*Varieties.*] This ſpecies is very extenſive in ſuppoſed varieties, bearing the above ſpecific diſtinction, ſeveral of which have been formerly conſidered as diſtinct ſpecies, but now ranged among the varieties of the Gallican Roſe, conſiſting of the following noted varieties.

*Common Red Officinal Roſe.*] Grows erect, about three or four feet high, having ſmall branches, with but few prickles; and large, ſpreading, half-double, deep-red flowers.

The flowers being aſtringent, are uſed in medicine, being gathered for that uſe while in the bud, or before they begin to open; and they fetch a good price at market, where they are ſold by the peck, or buſhel, and pay ſufficiently for the culture of a large quantity of plants, for which purpoſe the London gardeners plant them in cloſe ranges, forming low hedges, a foot or two high, keeping them down by an annual clipping in autumn; and they produce great quantities of flowers.

*Roſa Mundi, (Roſe of the World) or ſtriped Red Roſe.*] Is a variety of the common Red Roſe, growing but three or four feet high; having large ſpreading ſemi-double red flowers, beautifully ſtriped with white—and deep-red.

*York and Lancaſter variegated Roſe.*] Grows five, ſix, or eight feet high, or more; bearing variegated red flowers; conſiſting of a mixture of red and white; alſo frequently diſpoſed in elegant ſtripes, ſometimes in half of the flower, and ſometimes in ſome of the petals.

*Monthly Roſe.*] Grows about four or five feet high, with green, very prickly ſhoots; producing middle ſized, moderately double, delicate flowers, of different colours in the varieties.

*Varieties are.*] Common red-flowered Monthly Roſe—bluſh-flowered—white-flowered—ſtriped-flowered.—All of which blo both early and late, and often produce flowew ſeveral months in the year, as May, June, and July: and frequently again in Auguſt, or September, and ſometimes in fine mild ſeaſons, continues till November or December: hence the name Monthly Roſe.

It is generally the earlieſt blowing Roſe; but as it begins to ſhoot early in the ſpring, the buds are often cut by the froſt, ſo as to prevent their blowing fair and plenteouſly; the plants ſhould therefore have a ſomewhat ſheltered warm ſituation; ſome ſhould alſo be planted againſt a warm wall; and is a proper ſort to pot for forcing.

*Double Virgin Roſe.*] Grows five or ſix feet high, having greeniſh branches with ſcarce any ſpines; and with large, double, pale-red, very fragrant flowers.

*Red Damaſk Roſe.*] Grows eight or ten feet high, having greeniſh branches, armed with ſhort aculea; and moderately-double, fine ſoft-red, very fragrant flowers.

*White Damaſk Roſe.*] Grows eight or ten feet high, with greeniſh very prickly branches, and whitiſh-red flowers, becoming gradually of a whiter colour.

*Bluſh Belgic Roſe.*] Grows three or four feet high, or more; having greeniſh prickly branches, five or ſeven lobed leaves, and numerous, very double, bluſh-red flowers, with ſhort petals, evenly arranged.

*Red Belgic Roſe.*] Having greeniſh and red ſhoots and leaves, and fine double deep-red flowers.

*Velvet Roſe.*] Grows three or four feet high armed

armed with but few prickles; producing large velvet-red flowers, compriſing ſemi-double, and double varieties, all very beautiful Roſes.

*Marbled Roſe.*] Grows four or five feet high, having browniſh branches, with but few prickles; and large, double, finely-marbled, red-flowers.

*Red and Yellow Auſtrian Roſe.*] Grows five or ſix feet high, having ſlender, reddiſh branches, armed with ſhort, browniſh aculea; and with flowers of a reddiſh copper colour on one ſide, the other ſide yellow.

This is a curious variety, and the flowers aſſume a ſingularly agreeable appearance.

*Yellow Auſtrian Roſe.*] Grows five or ſix feet high, having reddiſh very prickly ſhoots; and numerous bright-yellow flowers.

*Double Yellow Roſe.*] Grows ſix or ſeven feet high; browniſh branches, armed with numerous large and ſmall yellowiſh prickles; and large very double yellow flowers.

*Frankfort Roſe.*] Grows eight or ten feet high, is a vigorous ſhooter, with browniſh branches, thinly armed with ſtrong prickles; and produces largiſh, double, purpliſh-red flowers, that blow irregularly, and have but little fragrance.

All the above ſorts are ſuppoſed to be varieties of the *Gallican Roſe*; though it is probable ſome of them may alſo appear to belong to other ſpecies, particularly to the *Roſa Centifolia*, and *Roſa Alba*.

[4]Rosa *Centifolia.*

*Hundred-leaved Red Roſe*, &c.] Grows from about three or four to ſix or eight feet high, in different ſorts, all of them hiſpid and prickly; pinnated three and five-lobed leaves; and large very double red flowers, having very numerous petals, and of different ſhades in the varieties.

Specific deſcription is,—Roſe with hiſpid and prickly ſtalks and branches, inermous, or unarmed petioles; hiſpid pedunculi, and oval hiſpid germina.

Varieties are,

*Common Dutch hundred-leaved Roſe.*] Grows three or four feet high, with erect greeniſh branches, but moderately armed with prickles; and large, remarkably double red-flower, with ſhort regularly arranged petals.

*Bluſh hundred-leaved Roſe.*] Grows like the other, with large, very double, pale-red flowers.

*Provence Roſe.*] Grows five or ſix feet, with greeniſh-brown, prickly branches, and very large double globular red flowers, with large petals folding over one another, more or leſs in the varieties.

*Varieties are.*] Common Red Provence Roſe, and Pale Provence Roſe; both of which having larger, and ſomewhat looſer petals than the following ſort. — Cabbage Provence Roſe; having the petals cloſely folded over one another like cabbages—Dutch Cabbage Roſe, very large, and cabbages tolerably—Chilling Provence Roſe—Great Royal Roſe, grows ſix or eight feet high, producing remarkably large, ſomewhat looſe, but very elegant flowers.—All theſe are large double red flowers, ſomewhat globular at firſt blowing, becoming gradually a little ſpreading at top, and are all very ornamental fragrant Roſes.

*Moſs Provence Roſe.*] Suppoſed a variety of the common Provence; grows erectly, four or five feet high, having browniſh ſtalks and branches, very cloſely armed with ſhort prickles, and double, crimſon-red flowers; having the calix and upper part of the peduncle ſurrounded with a rough moſſy-like ſubſtance, effecting a curious ſingularity.

This a fine delicate Roſe, of a high fragrance, which, together with its moſſy calix, renders it of great eſtimation as a curioſity.

All the above varieties are ſuppoſed to belong to the ſpecies *Roſa Centifolia*, which however is not poſitively aſcertained, as ſome of them ſometimes nearly ſhew themſelves varieties alſo of the *Roſa Gallica*, &c. However, they are all fine large double Roſes, of very numerous petals, cloſely arranged, and in ſeveral ſorts, cloſely folded over one another, particularly the common hundred-leaved Roſe, and Provence kinds; but the Cabbage Provence moſt of all; the Common Provence, and Cabbage-Roſe, are the moſt generally cultivated ſorts in moſt gardens, as being very elegant Roſes, as well as poſſeſs a remarkable fine fragrance: all the other varieties of this ſpecies have alſo a due ſhare of merit as capital Roſes, and will effect a delightful diverſity in a collection.

From the great multiplicity of the petals of this ſpecies, &c. it derives the name *Centifolia*, or hundred-leaved Roſe.

[5]Rosa *Cinnamomea.*

*Cinnamon Roſe.*] Grows five or ſix feet high, or more, with purpliſh branches, thinly aculeated; pinnated five or ſeven-lobed leaves, having almoſt inermous petioles; ſmooth pedunculi, and ſmooth globular germina; and ſmall purpliſh-red cinnamon-ſcented flowers, early in May.

*Varieties.*] With double flowers—ſingle-flowered.

[6]Rosa *Alpina.*

*Alpine inermous Roſe.*] Grows five or ſix feet

feet high, having ſmooth, or unarmed, reddiſh branches, pinnated ſeven-lobed ſmooth leaves, ſomewhat hiſpid pedunculi, oval germina, and deep-red ſingle flowers; appearing in May.

This ſpecies, as being free from all kind of armature, common to the other ſorts of Roſes, is eſteemed as a ſingularity; and from its inermous property, is often called the Virgin Roſe.

[7]Rosa *Carolina.*

*Carolina and Virginia Roſe*, &c.] Grows ſix or eight feet high, or more; having ſmooth, reddiſh branches, very thinly aculeated; pinnated, ſeven-lobed, ſmooth leaves, with prickly foot-ſtalks; ſomewhat hiſpid, pedunculi, globoſe hiſpid germen, and ſingle red flowers, in cluſters, appearing moſtly in Auguſt and September.

*Varieties.*] Dwarf Penſylvanian Roſe, with ſingle and double red flowers—American pale-red Roſe.

This ſpecies and varieties grow naturally in different parts of North America; they effect a fine variety in our gardens, and are in eſtimation for their ſerotinous, or late-flowering property, as they often continue in blow from Auguſt until October; and the flowers are ſucceeded by numerous, red, berry-like heps in autumn, cauſing a variety all winter.

[8]Rosa *Villoſa.*

*Villoſe Apple-bearing Roſe.*] Grows ſix or eight feet high, having ſtrong, erect, browniſh, ſmooth branches; aculeated ſparſedly pinnated, ſeven-lobed, villoſe, or hairy-leaves, downy underneath, with prickly foot-ſtalks; hiſpid peduncles, globular, prickly germen; and large ſingle red flowers, ſucceeded by large, round, prickly heps, as big as little apples.

This ſpecies merits admittance in every collection as a curioſity for the ſingularity of its fruit, both for variety and uſe; for it having a thick pulp of an agreeable acid reliſh, is often made into a tolerable good ſweet-meat.

[9]Rosa *Pimpinelliſolia.*

*Burnet-leaved Roſe.*] Grows about a yard high, aculeated ſparſedly; ſmall, neatly pinnated, ſeven-lobed leaves, having obtuſe folioles, and rough petioles; ſmooth peduncles, globular, ſmooth germen; and ſmall ſingle flowers.

*Varieties.*] With red flowers — and with white flowers.

They grow wild in England, &c. and are cultivated in ſhrubberies for variety.

[10]Rosa *Spinoſiſſima.*

*Moſt Spinous, Dwarf Burnet-leaved Roſe, commonly called Scotch Roſe.*] Grows but two or three feet high, very cloſely armed with ſpines; ſmall, neatly pinnated, ſeven-lobed leaves, with prickly foot-ſtalks; prickly pedunculi; oval, ſmooth germen; and numerous, ſmall, ſingle flowers, ſucceeded by round, dark-purple heps.

*Varieties.*] Common white-flowered—red-flowered — ſtriped-flowered — marbled-flowered.

They grow naturally in England, and Scotland, &c. the firſt variety riſes near a yard high, the others but one or two feet; all of which are ſingle-flowered; but the flowers being numerous all over the branches, make a pretty appearance in a collection.

[11]Rosa *Eglanteria.*

*Eglantine Roſe, or Sweet Briar.*] Grows five or ſix feet high, having green branches, armed with ſtrong ſpines ſparſedly; pinnated, ſeven-lobed, odoriferous leaves, with acute folioles, and rough foot-ſtalks; ſmooth pedunculi, globular ſmooth germina; and ſmall pale-red flowers.

*Varieties.*] Common ſingle-flowered—ſemi-double-flowered — double-flowered — bluſh double-flowered—yellow-flowered.

This ſpecies grows naturally in ſome parts of England, and in Switzerland.

It claims culture in every garden for the odoriferous property of its leaves; and ſhould be planted in the borders, and other compartments contiguous to walks, or near the habitation, where the plants will impart their refreſhing fragrance very profuſely all around; and the young branches are excellent for improving the odour of noſe-gays and bow-pots; and for which purpoſe the London gardeners raiſe great quantities for ſale, of the common ſingle kind, which they effect by ſeed, ſowing it in autumn, in drills near an inch deep; and the plants may either remain, or be tranſplanted where required. See the *Propagation.*

But the double-flowered and yellow variety are continued the ſame, only by ſuckers and layers.

[12]Rosa *Moſchata.*

*Muſk-Roſe; ſuppoſed to be a Variety only of the Ever-green Muſk-Roſe.*] Hath weak, ſmooth, green ſtalks and branches, riſing by ſupport, from ſix to eight or ten feet high, or more, thinly armed with ſtrong ſpines; pinnated, ſeven-lobed, ſmooth leaves, with prickly foot-ſtalks; hiſpid peduncles; oval hiſpid germen;

armed with but few prickles; producing large velvet red flowers, compriſing ſemi-double, and double varieties, all very beautiful Roſes.

*Marbled Roſe.*] Grows four or five feet high, having browniſh branches, with but few prickles; and large, double, finely-marbled, red-flowers.

*Red and Yellow Auſtrian Roſe.*] Grows five or ſix feet high, having ſlender, reddiſh branches, armed with ſhort, browniſh aculea; and with flowers of a reddiſh copper colour on one ſide, the other ſide yellow.

This is a curious variety, and the flowers aſſume a ſingularly agreeable appearance.

*Yellow Auſtrian Roſe.*] Grows five or ſix feet high, having reddiſh very prickly ſhoots; and numerous bright-yellow flowers.

*Double Yellow Roſe.*] Grows ſix or ſeven feet high; browniſh branches, armed with numerous large and ſmall yellowiſh prickles; and large very double yellow flowers.

*Frankfort Roſe.*] Grows eight or ten feet high, is a vigorous ſhooter, with browniſh branches, thinly armed with ſtrong prickles; and produces largiſh, double, purpliſh-red flowers, that blow irregularly, and have but little fragrance.

All the above ſorts are ſuppoſed to be varieties of the *Gallican Roſe*; though it is probable ſome of them may alſo appear to belong to other ſpecies, particularly to the *Roſa Centifolia*, and *Roſa Alba*.

[4]Rosa *Centifolia.*

*Hundred-leaved Red Roſe*, &c.] Grows from about three or four to ſix or eight feet high, in different ſorts, all of them hiſpid and prickly; pinnated three and five-lobed leaves; and large very double red flowers, having very numerous petals, and of different ſhades in the varieties.

Specific deſcription is,—Roſe with hiſpid and prickly ſtalks and branches, inermous, or unarmed petioles; hiſpid pedunculi, and oval hiſpid germina.

Varieties are,

*Common Dutch hundred-leaved Roſe.*] Grows three or four feet high, with erect greeniſh branches, but moderately armed with prickles; and large, remarkably double red-flower, with ſhort regularly arranged petals.

*Bluſh hundred-leaved Roſe.*] Grows like the other, with large, very double, pale-red flowers.

*Provence Roſe.*] Grows five or ſix feet, with greeniſh-brown, prickly branches, and very large double globular red flowers, with large petals folding over one another, more or leſs in the varieties.

*Varieties are.*] Common Red Provence Roſe, and Pale Provence Roſe; both of which having larger, and ſomewhat looſer petals than the following ſort. — Cabbage Provence Roſe; having the petals cloſely folded over one another like cabbages — Dutch Cabbage Roſe, very large, and cabbages tolerably — Chilling Provence Roſe — Great Royal Roſe, grows ſix or eight feet high, producing remarkably large, ſomewhat looſe, but very elegant flowers. — All theſe are large double red flowers, ſomewhat globular at firſt blowing, becoming gradually a little ſpreading at top, and are all very ornamental fragrant Roſes.

*Moſs Provence Roſe.*] Suppoſed a variety of the common Provence; grows erectly, four or five feet high, having browniſh ſtalks and branches, very cloſely armed with ſhort prickles, and double, crimſon-red flowers; having the calix and upper part of the peduncle ſurrounded with a rough moſſy-like ſubſtance, effecting a curious ſingularity.

This a fine delicate Roſe, of a high fragrance, which, together with its moſſy calix, renders it of great eſtimation as a curioſity.

All the above varieties are ſuppoſed to belong to the ſpecies *Roſa Centifolia*, which however is not poſitively aſcertained, as ſome of them ſometimes nearly ſhew themſelves varieties alſo of the *Roſa Gallica*, &c. However, they are all fine large double Roſes. of very numerous petals, cloſely arranged, and in ſeveral ſorts, cloſely folded over one another, particularly the common hundred-leaved Roſe, and Provence kinds; but the Cabbage Provence moſt of all; the Common Provence, and Cabbage-Roſe, are the moſt generally cultivated ſorts in moſt gardens, as being very elegant Roſes, as well as poſſeſs a remarkable fine fragrance: all the other varieties of this ſpecies have alſo a due ſhare of merit as capital Roſes, and will effect a delightful diverſity in a collection.

From the great multiplicity of the petals of this ſpecies, &c. it derives the name *Centifolia*, or hundred-leaved Roſe.

[5]Rosa *Cinnamomea.*

*Cinnamon Roſe.*] Grows five or ſix feet high, or more, with purpliſh branches, thinly aculeated; pinnated five or ſeven-lobed leaves, having almoſt inermous petioles; ſmooth pedunculi, and ſmooth globular germina; and ſmall purpliſh-red cinnamon-ſcented flowers, early in May.

*Varieties.*] With double flowers—ſingle-flowered.

[6]Rosa *Alpina.*

*Alpine inermous Roſe.*] Grows five or ſix feet

feet high, having ſmooth, or unarmed, reddiſh branches, pinnated ſeven-lobed ſmooth leaves, ſomewhat hiſpid pedunculi, oval germina, and deep-red ſingle flowers; appearing in May.

This ſpecies, as being free from all kind of armature, common to the other ſorts of Roſes, is eſteemed as a ſingularity; and from its inermous property, is often called the Virgin Roſe.

[7]Rosa *Carolina.*

*Carolina and Virginia Roſe*, &c.] Grows ſix or eight feet high, or more; having ſmooth, reddiſh branches, very thinly aculeated; pinnated, ſeven-lobed, ſmooth leaves, with prickly foot-ſtalks; ſomewhat hiſpid, pedunculi, globoſe hiſpid germen, and ſingle red flowers, in cluſters, appearing moſtly in Auguſt and September.

*Varieties.*] Dwarf Penſylvanian Roſe, with ſingle and double red flowers—American pale-red Roſe.

This ſpecies and varieties grow naturally in different parts of North America; they effect a fine variety in our gardens, and are in eſtimation for their ſerotinous, or late-flowering property, as they often continue in blow from Auguſt until October; and the flowers are ſucceeded by numerous, red, berry-like heps in autumn, cauſing a variety all winter.

[8]Rosa *Villoſa.*

*Villoſe Apple-bearing Roſe.*] Grows ſix or eight feet high, having ſtrong, erect, brownish, ſmooth branches; aculeated ſparſedly pinnated, ſeven-lobed, villoſe, or hairy-leaves, downy underneath, with prickly foot-ſtalks; hiſpid peduncles, globular, prickly germen; and large ſingle red flowers, ſucceeded by large, round, prickly heps, as big as little apples.

This ſpecies merits admittance in every collection as a curioſity for the ſingularity of its fruit, both for variety and uſe; for it having a thick pulp of an agreeable acid reliſh, is often made into a tolerable good ſweet-meat.

[9]Rosa *Pimpinelliſolia.*

*Burnet-leaved Roſe.*] Grows about a yard high, aculeated ſparſedly; ſmall, neatly pinnated, ſeven-lobed leaves, having obtuſe folioles, and rough petioles; ſmooth peduncles, globular, ſmooth germen; and ſmall ſingle flowers.

*Varieties.*] With red flowers — and with white flowers.

They grow wild in England, &c. and are cultivated in ſhrubberies for variety.

[10]Rosa *Spineſiſſima.*

*Moſt Spinous, Dwarf Burnet-leaved Roſe, commonly called Scotch Roſe.*] Grows but two or three feet high, very cloſely armed with ſpines; ſmall, neatly pinnated, ſeven-lobed leaves, with prickly foot-ſtalks; prickly pedunculi; oval, ſmooth germen; and numerous, ſmall, ſingle flowers, ſucceeded by round, dark-purple heps.

*Varieties.*] Common white-flowered — red-flowered — ſtriped-flowered — marbled-flowered.

They grow naturally in England, and Scotland, &c. the firſt variety riſes near a yard high, the others but one or two feet; all of which are ſingle-flowered; but the flowers being numerous all over the branches, make a pretty appearance in a collection.

[11]Rosa *Eglanteria.*

*Eglantine Roſe, or Sweet Briar.*] Grows five or ſix feet high, having green branches, armed with ſtrong ſpines ſparſedly; pinnated, ſeven-lobed, odoriferous leaves, with acute folioles, and rough foot-ſtalks; ſmooth pedunculi, globular ſmooth germina; and ſmall pale-red flowers.

*Varieties.*] Common ſingle-flowered—ſemi-double-flowered — double-flowered — bluſh double-flowered—yellow-flowered.

This ſpecies grows naturally in ſome parts of England, and in Switzerland.

It claims culture in every garden for the odoriferous property of its leaves; and ſhould be planted in the borders, and other compartments contiguous to walks, or near the habitation, where the plants will impart their refreſhing fragrance very profuſely all around; and the young branches are excellent for improving the odour of noſe-gays and bow-pots; and for which purpoſe the London gardeners raiſe great quantities for ſale, of the common ſingle kind, which they effect by ſeed, ſowing it in autumn, in drills near an inch deep; and the plants may either remain, or be tranſplanted where required. See the *Propagation.*

But the double flowered and yellow variety are continued the ſame, only by ſuckers and layers.

[12]Rosa *Moſchata.*

*Muſk-Roſe; ſuppoſed to be a Variety only of the Ever-green Muſk-Roſe.*] Hath weak, ſmooth, green ſtalks and branches, riſing by ſupport, from ſix to eight or ten feet high, or more, thinly armed with ſtrong ſpines; pinnated, ſeven-lobed, ſmooth leaves, with prickly foot-ſtalks; hiſpid peduncles; oval hiſpid germen;

and all the branches terminated by large umbellate cluſters, of pure-white, muſk-ſcent d flowers in Auguſt, &c.

[13]Rosa *Sempervirens.*

*Sempervirent, or Ever-green Muſk Roſe.*] Hath ſomewhat trailing ſtalks and branches, riſing by ſupport five or ſix feet high, or more, having a ſmooth bark, armed with prickles; pinnated, five-lobed, ſmooth, ſhining, evergreen leaves, with prickly petioles; hiſpid pedunculi; oval hiſpid germen; and all the branches terminated by cluſters of pure-white flower of a muſky fragrance; appearing the end of July, and in Auguſt.

The ſempervirent property of this elegant ſpecies, renders it a curioſity among the Roſy tribe; it alſo makes a fine appearance as a flowering ſhrub.

*Variety.*] Deciduous Muſk-Roſe, abovementioned; ſuppoſed to be a variety of this ſpecies.

This ſpecies and variety flower in Auguſt; remarkable for producing them numerouſly in cluſters, continuing in ſucceſſion till October or November. They ſhould generally be planted againſt ſome wall, or be allowed ſome ſupport.

All the above thirteen ſpecies of *Roſa*, and their reſpective varieties, are of the ſhrub kind; all deciduous, except the laſt ſort, and of hardy growth, ſucceed in any common ſoil and ſituation, and flower annually in great abundance from May till October, in different ſorts; though the general flowering ſeaſon for the principal part of them is June and July; but in a full collection of the different ſpecies, the blow is continued in conſtant ſucceſſion ſeveral months, even ſometimes from May till near Chriſtmas; producing their flowers univerſally on the ſame years ſhoots, riſing from thoſe of the year before, generally on long pedunculi, each terminated by one or more Roſes, which, in their characteriſtic ſtate, conſiſts each of five large petals, and many ſtamina; but in the doubles, the petals are very numerous; and in ſome ſorts, the flowers are ſucceeded by fruit ripening to a red colour in autumn and winter; from the ſeed of which the plants may be raiſed; but the moſt certain and eligible mode of propagating moſt of the ſorts is by ſuckers and layers; and by which methods they may be increaſed very expeditiouſly in great abundance.——See their *Propagation.*

All theſe ſhrubs are fine ornamental furniture for every garden, in the exceeding beauty and fragrance of their elegant flowers; and as they will all grow any where without trouble, and may be obtained at all the nurſeries, at moderate rates, every garden may be eaſily furniſhed with a full collection; and being poſſeſſed of a few of each ſort, they will moſt of them ſoon encreaſe the ſtock conſiderably by ſuckers.

The ſeaſon for planting all the ſorts is, any time in open weather from October till March, and they will all flower in perfection the following ſummer; but if occaſion requires they may be tranſplanted ſo late as any time in April, or even the beginning of May, which late planting is ſometimes deſignedly practiſed to a few annually, to obtain a late bloom in autumn; however, the earlier the planting is performed, the ſtronger the plants will flower.

When theſe ſhrubs are deſigned for the ſhrubbery, and common flower borders, they ſhould be planted ſingly; and may be trained with a ſingle ſtem, one, two, or more feet high, and then encouraged to branch out into a buſhy head; though when they are required to exhibit a more buſhy growth, they are often ſuffered to branch away immediately from the bottom; as they will blow plentifully in any mode off training; however, I ſhould adviſe keeping them to a ſingle ſtem below, and let them form a buſhy head upward. As to their culture, very little is required; which is only clearing the bottom from ſuckers, in winter, which will ſerve for new plants, and thin the head occaſionally, when grown too thick and confuſed, and reduce any long rambling ſhoot, and cut out dead wood; but as theſe ſhrubs produce their flowers generally on the young ſhoots, ſome clip them down a little annually in autumn or winter, to force out a greater quantity of flowers, which however will probably be proportionally ſmaller; though thoſe who want them for ſale in the markets, &c. endeavour to procure as large a quantity as poſſible.

But where large quantities of the flowers are required particularly for ſale, as is the caſe about London, the gardeners generally plant the ſhrubs in cloſe rows, forming a ſort of hedge, putting them in by *trench-planting*, a foot diſtance in the row; and in their culture keep them down to one, two, or three feet high, according to the ſorts, by ſhearing or clipping them annually, in autumn or winter, at top and ſides, in order to force out a greater quantity of laterals the following year for flowering, as before obſerved.

Some

Some plants of the beſt ſorts may alſo be planted againſt a warm wall, to forward their ſhooting for an early bloom; a few of the Monthly Roſes in particular, alſo the Provence kinds, and cinnamon Roſe, &c. But as the Monthly Roſe ſhoots early in the ſpring, as formerly hinted, it is always proper to have ſome plants of that ſort againſt ſome warm fence, both for ſhelter, and to forward the bloom.

A few plants of the beſt ſorts of Roſes ſhould alſo be potted to move occaſionally to adorn any particular compartment.

Likewiſe, where there is convenience of forcing-frames, or hot-houſes, &c. it is proper alſo to pot ſome prime ſorts to force for an early ſpring bloom; for by aid of the above departments of artificial heat, Roſes may be blowed almoſt any time in winter, or early in ſpring; for which purpoſe, having ſome plants of the Monthly Roſe, common Provence, and Moſs Provence, or any other choice ſorts, in pots, which in winter, may be placed in any forcing-frames, worked either by dung, bark, or fire heat, or placed in a hot-houſe, they may be brought to flower in January, February, and March, and continued in ſucceſſion till the plants in the natural ground begin to flower, by having different ſupplies of plants placed for forcing at two or three weeks interval. A quantity of plants ſhould generally be potted for this uſe annually, and if they have a ſummer's growth in the pots, plunged in the ground, previous to the time of forcing, they will be more firmly rooted, ſo as to flower in greater perfection. See FORCING-FRAME.

Many of the gardeners about London erect forcing-frames, or glaſs-houſes, with bark-pits on purpoſe for forcing Roſes, as they are generally ready ſale, at an early ſeaſon, both the pots of plants in flower, and the Roſes gathered as noſegays; and fetch an extraordinary great price, which pays ſufficiently for forcing.

*Method of Propagation.*

The propagation of all the ſorts is by ſuckers—layers—budding—and ſome ſorts by ſeeds.—But ſuckers is the moſt common and expeditious method for propagating moſt of the ſpecies.

By Suckers.—Moſt of the ſorts of Roſes ſend up many ſuckers annually from the root, attaining from one or two to three or four feet height, or more, in one ſummer, and by theſe the ſhrubs may be expeditiouſly propagated in great plenty; they may be taken up in autumn, winter, or early inſpring, with ſome fibres to their bottom; and the ſtrongeſt may be planted out finally, and the weakeſt in nurſery lines for a year or two, or longer; they will readily grow, and will moſt of them produce flowers the following ſummer.

When theſe ſhrubs have grown into large bunches, with many ſuckers grown up to ſtems from the root, the whole may be taken up and ſlipped, or divided into ſo many ſeparate plants, and planted out, as above.

Obſerve, that as the Moſs Roſe, Muſk Roſe, Apple-bearing Roſe, and ſome others, furniſh ſuckers but ſparingly, ſo in default thereof muſt have recourſe to layers, or budding; particularly for the Moſs Provence.

By Layers.—All the ſorts of theſe plants will grow by layers of the young ſhoots; and is an effectual method of propagation, for ſuch ſorts in particular, that ſparingly furniſh ſuckers, as the Moſs Provence, &c. as aforeſaid; and that to obtain plenty of ſhoots for laying, a quantity of the plants ſhould be planted for ſtools; which being headed down low, they will throw out plenty of ſhoots near the ground in ſummer, for laying in autumn or winter following, by ſlit or twiſt-laying, they will be rooted by next autumn, and fit for tranſplantation, in nurſery rows; though ſometimes the Moſs Roſe, &c. require two years before they are tolerably well rooted; but of theſe ſorts, you may alſo try layers of he young tender ſhoots of the year, layed in ſummer, any time in June, they will probably root a little the ſame ſeaſon. However, the layers of all the ſorts, after being properly rooted, ſhould be taken up in autumn, and planted in the nurſery, to have a one or two years growth, or to remain till wanted.

By Budding.—This is ſometimes practiſed in propagating ſome choice ſorts that ſeldom ſend up ſuckers, ſuch as the Moſs Provence, &c. as aforeſaid; alſo, when intended to have two, three, or more different ſorts of Roſes upon the ſame tree, for curioſity; working them upon the Frankfort, or any other ſtrong-ſhooting Roſe ſtocks raiſed from ſuckers.

By Seeds.—This is ſometimes practiſed to try to obtain new varieties; alſo ſometimes for raiſing ſome particular permanent ſpecies, ſuch as the Canine Roſe, Burnet-leaved Roſe, Scotch Roſe, Apple-bearing Roſe, ſingle Sweet Briar, and ſuch others as continue the ſame by ſeedlings; ſowing them generally in au-

tumn ſoon after they are ripe, and they will ſometimes riſe the following ſpring; as if not ſowed till the ſpring ſeaſon, moſt of the ſorts are apt to remain till the ſecond year before they riſe freely; ſow them however, in any bed of light earth, either in ſhallow drills, or all over the ſurface, covering them half an inch deep; and when the ſeedlings are a year old, tranſplant them in nurſery-rows.

Obſerve however, that the double kinds, and other particular varieties of the ſpecies in general, caannot be continued the ſame with certainty by ſeeds, ſo muſt always be propagated by ſuckers or layers, &c.

But remark the common ſingle Sweet Briar, when required in any conſiderable quantity, ſhould generally be raiſed from ſeed, ſowing it in drills half an inch deep, either to remain, or for tranſplantation; though when deſigned to form a ſort of hedge of this plant, to produce a crop of ſhoots to cut for the ſupply of markets during the ſummer, it is eligible to ſow the ſeed at once in a drill where the plants are to ſtand.

ROSMARINUS, Roſemary.

It conſiſts of one hardy ſhrubby ever-green, compriſing ſome varieties, proper for the kitchen garden and ſhrubbery; all of which are adorned with narrow ſtiff leaves, and numerous, ſmall, monopetalous, ringent flowers, along the ſides of the ſhoots.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is monophyllous, the mouth erect and bilabiated, the upper lip, being entire, the under one bifid.—COROLLA, is monopetalous, tubular below, and ringent above, having the upper lip ſhort and bifid, and the under one reflexed and trifid, with the middle ſegment largeſt.—STAMINA, two ſubulate filaments, inclining towards the upper lip, and ſimple anthera.—PISTILLUM, a quadrifid germen; a ſtyle like the ſtamina of the ſame length and ſituation, and a ſimple acute ſtigma.—PERICARPIUM none, four oval ſeeds lodged in the calix.

The ſpecies is,

ROSMARINUS *Officinalis.*

*Common Officinal Roſemary.*] Hath a ſhrubby ſtem branching numerouſly from the bottom upward, growing five or ſix feet high, cloſely garniſhed with linear ſtiff leaves; and numerous ſmall purpliſh flowers all along the upper part of the branches.

*Varieties.*] Common narrow-leaved Roſemary—broad-leaved—ſilver-ſtriped-leaved—gold-ſtriped-leaved.

All the varieties are tolerably hardy ever-greens, though the common green ſorts are the hardieſt; the ſtriped kinds are liable to ſuffer by hard froſts, if much expoſed, or planted in in wet ground, ſo ſhould have a warm ſituation and dry ſoil; ſome of theſe variegated kinds ſhould alſo be potted, in order to have ſhelter of a green-houſe in winter. It ſhould alſo be obſerved, that all the varieties of Roſemary ſhould generally have a dry ſoil; and if poor, ſandy, gravelly, or rubbiſhy, they will be more durable than in moiſt, rich land; in wet ſoils in particular, they are very liable to periſh in winter. However, all the ſorts will ſucceed in any common earth in a dry ſituation.

As to their uſes in gardening, the common green ſorts are employed as medical plants, &c. and both green and variagated kinds claim admittance in the ſhrubbery, to increaſe the variety in the ever-green collection, allowing them a dry ſoil, and the ſtriped ſorts in particular a warm ſituation, as above obſerved; plant ſome of theſe ſorts alſo againſt a warm fence, as a place of greater ſhelter to protect them in winter.

But it is proper always to keep a few plants of the ſtriped ſorts in pots, and place them in the green-houſe collection for winter ſhelter; and where they will alſo effect a pretty variety.

The leaves and flowers of Roſemary are uſed in medicine.

*Method of Propagation.*

They are all eaſily propagated by ſlips or cuttings, and by layers.

By Slips and Cuttings.—In March or April, ſlip or cut off a quantity of young ſhoots, from about five or ſix to eight or ten inches long, and ſtrip off the lower leaves; then plant them in a border of light earth, in rows a foot aſunder, and give a good watering, repeating it frequently till they are rooted, which they will effect in a ſhort time, the ſame year, ſhoot at top, and become tolerable little plants by autumn, when about the begining or middle of September, or in ſpring following, they may be tranſplanted where they are deſigned to remain.

By Layers.—In ſpring or autumn, lay down any of the convenient lower young branches in the earth, they will be well rooted by autumn following.

ROYENA, African Bladder Nut.

The plants are ſhrubby ever-green exotics for the green-houſe collection; garniſhed with oval, and ſpear-ſhaped leaves; and monopetalous,

nopatalous, five-parted reflexed flowers along the ſides of the branches.

Claſs and order, *Decandria Digynia.*

*Characters.*] CALIX, is monophyllous, five-parted at top, and permanent.—COROLLA, is monopetalous, with a tube the length of the calix, and divided above into five oval reflexed ſegments.—STAMINA, ten very ſhort filaments, having oblong didymous erect antheræ.—PISTILLUM, an oval germen, two ſtyles, and ſimple ſtigma.—PERICARPIUM, an oval quadrifulcated, and quadrivalved unilocular capſule, having four oblong triangular nuts.

The ſpecies are,

[1]ROYENA *lucida.*

*Lucid African Bladder Nuts.*] Hath a ſhrubby upright ſtem, branching eight or ten feet high; oval, ſomewhat rough but ſhining green leaves, alternately; and white flowers at the ſides of the branches.

[2]ROYENA *Glabra.*

*Glabrous African Bladder Nut.*] Hath a ſhrubby upright ſtem, branching five or ſix feet high; ſmall, lanceolate, ſmooth leaves; and ſmall white flowers at the ſides of the branches.

[3]ROYENA *Hirſuta.*

*Hairy African Bladder Nut.*] Hath a ſhrubby upright ſtem, branching alternate-ways, ſix or ſeven feet high, lanceolate hairy leaves; and purpliſh flowers at the ſides of the branches.

Theſe three ſhrubs being natives of the Cape of Good Hope, require ſhelter here in winter, ſo muſt always be kept in pots, and placed among the green-houſe plants; where they will form a good variety, as ever-greens; and will flower in July or Auguſt; but the flowers are ſmall, and of but little beauty, ſucceeded ſometimes by ripe capſules, particularly the firſt and ſecond ſorts; their culture is the ſame as other ſhrubby green-houſe plants.

They are propagated by ſeed, layers, and cuttings.

By Seed.—Sow it in ſpring, in pots, and plunge them in a bark-bed, or other hot-bed; and when the plants are three or four inches high, pot them off ſeparately.

By Layers.—Lay the young ſhoots of the year in ſummer, as they are unapt to ſtrike in the older wood.

By Cuttings.—In ſpring, plant ſome young ſhoots in pots, and plung them in a hot-bed.

RUBIA, Madder.

This genus conſiſts of two hardy herbaceous perennials, valuable for their roots, as a moſt uſeful commodity in dying red; they having thick ſucculent roots; long, thick procumbent ſtalks; ſpear-ſhaped radiant leaves; and campanulate, four-parted, yellow flowers, in ſpikes at the ends of the branches.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX, is ſmall, placed on the germen, and four-parted.—COROLLA, is monopetalous, bell-ſhaped, and four-parted at top.—STAMINA, four awl-ſhaped, ſhort filaments, having ſimple anthera.—PISTILLUM, a didymous germen under the calix; ſlender ſtyle bifid at top, and headed ſtigmas.—PERICARPIUM, two ſmooth berries joined together; each having one roundiſh umbilicated ſeed.

The ſpecies are,

[1]RUBIA *Tinctorum.*

*Common Dying Madder.*] Hath a long, thick, fibrated, fleſhy, reddiſh root, ſending up large four-cornered, jointed, procumbent ſtalks, five or ſix feet long, branching by pairs, croſſing alternately; garniſhed at each joint with ſix ſpear-ſhaped leaves in a verticillus, or radius; and ſmall yellow flowers, collected in looſe ſpikes at the ſides and ends of the branches.

It is a native of Italy, and about Montpelier in France, but grows freely here in the open ground.

[2]RUBIA *Peregrina.*

*Wild quaternate-leaved Madder.*] Hath thickiſh, fibrated, ſpreading roots; ſlender, four-cornered, procumbent, branchy ſtalks; garniſhed at each joint with quarternate, ſhort, rough leaves, and cluſters of yellow flowers.

This ſort is ſuppoſed to be a native of England, as it is not known to grow naturally in any other part of the world.

Both theſe ſpecies of Madder are herbaceous, of hardy growth; perennial in root, ſend up ſtalks in ſpring, and flower in June and July, ſucceeded by ſeeds in autumn; but thoſe of the *Rubia Tinctorum*, do not always ripen in England; it however multiplies exceedingly by ſuckers for propagation.

Theſe plants are ſometimes cultivated in gardens, in any open compartments, for variety.

But the chief merit of the plants is in their roots, to uſe for dying red, &c. And are alſo uſed in medicine, which taken inwardly, tinges the urine of a deep-red colour; but the *Rubia Tinctorum* in particular, is in greateſt eſtimation for the dyer's purpoſe. And is cultivated

tivated in great quantities in fields abroad, in Holland, &c. for the roots aforeſaid, as a very valuable commodity both for dyers and calico-printers; being propagated generally by ſuckers, or off-ſets, which are taken off in the ſpring, and planted in a light deep ſoil, in rows too feet aſunder, and require two or three years growth for the roots to attain perfection. They are alſo cultivated in ſome parts of England for profit, as they are hardy enough, and increaſe abundantly by off-ſets or ſuckers from the root, and are ſometimes raiſed in tolerable perfection. However, as in ſome parts, after repeated experiments in its cultivation, the crops have no ways anſwered the purpoſe, occaſioned probably by the ſoil not being ſuitable, or not properly planted and managed; therefore, at the firſt trial, it is adviſeable to plant only a ſmall quantity in different ſitu ations; and by obſerving the ſoil and method of culture of thoſe which ſucceeds beſt, it may a direction to the culture of larger quantities; and where crops of it ſucceed, it proves a very ſaleable article, and pays exceedingly well for its cultivation; and the roots may either be ſold to the dyers, or druggiſts, or thoſe who prepare them for uſe; though abroad the great Madder planters erect ſtoves and kilns for drying it; and ſtamping-mills for reducing it to powder, to render it more portable to ſend to diſtant countries; but the roots for home conſumption may alſo be uſed freſh for dying; firſt waſhing them clean, then cut to pieces, and pounded in a mortar, and then put into the cauldron, or dying copper.

*Their Propagation and Culture.*

They are propagated by off-ſets or ſuckers, ariſing from the roots of old plants in the ſpring; and ſhould be ſlipped off ſoon after they appear above ground; at which time, opening the earth round the roots, ſlip off the ſide-ſuckers with as much root part and fibres to each as poſſible, preſerving the tops entire; which ſhould be planted directly as adviſed below.

The ſeaſon for taking off the ſuckers and planting them is about the beginning, middle, or end of April, or beginning of May, when they appear above ground.

Obſerve, theſe plants delight in a light, rich, deep ſoil, or a light, deep, pliable, loamy land; and rather a ſomewhat low than high ſituation; which ſhould be deeply digged or ploughed in autumn, or winter; laying it in rough ridges to mellow and pulverize by the weather; and in ſpring levelled down for the reception of the plants; but for large quantities in fields, the ground ſhould be ploughed croſs-ways again, once or twice in the ſpring, and well harrowed.

Then in April, or early in May, provide a proper quantity of ſets, or ſuckers, as aforeſaid; and with a dibble plant them in rows two feet aſunder, and one diſtant in the row, putting each plant low enough in proportion to the length of its root, leaving moſt of the green top out of the ground, and cloſe the earth well about each ſet, as you go on: thus they will ſoon take root, and ſhoot at top. But ſome ſet theſe plants in beds, three rows length ways, at two feet diſtance, with wide alleys between bed and bed, in order for landing up the crown of the roots two or three inches deep, in winter.

In either mode of planting, they will ſhoot up into ſtalks the ſame year; but the roots will require two or three years growth before they are large enough for uſe; during which period, obſerve the following culture.

Keep them clean from weeds all the ſummer by broad-hoeing, in dry weather; and in autumn, when the ſtalks decay, cut them down, then ſlightly dig the ground between the rows, raiſing it ſomewhat ridge-ways along the rows of plants, an inch or two thick over their crowns; or if they are in beds, they may be landed up from the alleys the above depth. Next ſpring the roots will ſhoot up again ſtronger than before, and will ſoon cover the ground, and keep down weeds; in autumn following, the decayed haulm muſt be again cut down, and all weeds cleared away, ſlightly dig the ground, &c. as in the former year; and next ſpring the plants will ſtill riſe ſtronger, and the roots continue encreaſing in ſize; ſo as by the following October, having had three ſummers growth, they will be fit to take up for uſe.

The method of taking up the Madder-roots is by trenching the ground the way of the rows; beginning at one end of the ground, and open a two-feet wide trench cloſe along by the firſt row of plants, digging down to the depth of the roots to get them clean out to the bottom; then opening another trench cloſe to the next row, turning the earth thereof into the firſt; and ſo proceed trench and trench till the whole is taken up.

The Madder-roots thus taken up for uſe, are ſometimes uſed freſh for dying, preparing them by waſhing, and pounding them as before obſerved. But commonly when deſigned

for

for keeping, or to be ſent to a diſtance, are dried in ſome covered airy ſhed, then all mould being rubbed off, and the roots ſufficiently dry, they may then be ſold to thoſe who manufacture them for uſe, if not performed by the cultivator; which conſiſts of kiln drying them, or drying them in ſome ſtove-houſe, &c. then threſhed to beat off the outer ſkin, in order to ſeparate it from the inner part of the root, as being of inferior quality. The roots being then dried in a kiln about twenty-four hours, are removed to a mill, or pounding-houſe, where they are pounded in a long hollow oaken block, with ſtampers kept in motion by the mill; and when thus reduced to powder, is ſifted and put up in caſks for uſe.

But in Holland, where great quantities of this plant is cultivated, they have public kilns, mills, &c. where the cultivators ſend the roots to be manufactured. And there are treatiſes to be had here, exhibiting the kilns, mills, and other neceſſary accommodations for manufacturing this valuable material; together with full directions in the management thereof.

RUBUS, Bramble, or Raſpberry-buſh.

Conſiſts of under-ſhrubby and herbaceous perennials, valuable, ſome as fruit-bearing plants, and others for variety in the pleaſure ground, particularly the ſhrubby kinds; ſome being of erect growth, others long trailers, garniſhed with pinnated, ternate, and palmated leaves, in different ſpecies; and pentapetalous, icoſandrous flowers.

Claſs and order, *Icoſandria Polygynia.*

*Characters.*] CALIX, is monophyllous, five-parted and permanent. — COROLLA, five-roundiſh erecto-patent petals. — STAMINA, twenty or more ſhort filaments, having roundiſh compreſſed antheræ. — PISTILLUM, numerous germina, many capillary ſtyles from the ſides of the germens, crowned with permanent ſtigmas. — PERICARPIUM, a compound berry, compoſed of many roundiſh unilocular acini, each having one oblong ſeed.

There are about thirteen ſpecies, nine or ten of which are ligneous and ſhrubby; the others are ſomewhat herbaceous; but the moſt material ſorts are principally of the ligneous, or ſhrubby kind, and of which about five or ſix of the moſt noted ſpecies are cultivated in our gardens; the firſt of which *Rubus Idæus*, or Raſpberry-plant, is chiefly valued for its fruit; and the other ſorts as furniture for the ſhrubbery, &c. They are all deciduous plants of hardy growth, that ſucceed in any common ſoil and ſituation; and conſiſts of upright ligneous kinds, trailing ſhrubby kinds, and herbaceous kinds.

*Upright ligneous Kind.*

Under this head is compriſed the common Raſpberry-plant, and varieties; and other Raſpberry kinds. All of which riſing with ſeveral upright ligneous, or under-ſhrubby ſtems, from about three or four to ſix or ſeven feet high.

[1]RUBUS *Idæus.*

*Common Raſpberry Buſh.*] Riſes with ſeveral upright, ſtraight, ligneous, pithy ſtems from the root; four or five feet high, cloſely armed with ſhort prickles; pinnated, three and five-lobed rough leaves; and at the axillas and ends of the lateral ſhoots, ſmall cluſters of purpliſh and white flowers, ſucceded by ripe berries in July.

*Varieties.*] Common red Raſpberry—white-fruited Raſpberry — twice-bearing red, and white Raſpberry, producing the firſt crop of fruit in July, and the ſecond in September; and is eſteemed a curioſity — ſmooth Raſpberry, the ſtalks, &c. being devoid of armature.

The common red ſort grows wild in woods in England, but has been greatly improved by garden culture.

All the varieties bear plentifully, particularly the firſt three; they being all propagated by ſuckers, planted in any open ſituation, in rows four or five feet aſunder, and a yard diſtant in the rows, being planted in autumn, winter, or ſpring, they bear the ſummer following. Their mode of bearing is upon the year-old wood; that is, a ſupply of ſhoots riſing annually from the root; which, when a year old ſend out many ſmall laterals, and upon theſe the fruit is produced the ſame year; remarking the ſame individual ſhoots never bear but once; a ſucceſſion of young ſhoots or ſtems being ſent up annually from the root every ſummer for bearing; thoſe produced one year, bear the fruit the next, and then totally decay to the root, in winter following, they never ſurviving to bear a ſecond year, but are always ſucceeded by a plentiful ſupply that have ariſen from the bottom in ſummer for next year's bearing; ſo that every winter, all the decayed ſtalks that bore the fruit the preceding ſummer, muſt be broken down cloſe to the ground; they being readily diſtinguiſhed from the young ſucceſſion wood, which at the ſame time muſt be regularly thinned to four or five of the ſtrongeſt

ſhoots

ſhoots on each root; and theſe ſhould be topped to about a yard in height, or a little more or leſs, according to their ſtrength, and they will all branch out laterally the following ſpring; and upon the laterals the flowers and fruit are produced. — See the *Propagation and general Culture*.

The Raſpberry is in eſtimation both as eatable fruit, and for many culinary purpoſes, as for tarts, ſauces, &c. when ripe.

[2]RUBUS *Odorata*.

*Odoriferous Virginia flowering Raſpberry*.] Riſes with many upright, large, under-ſhrubby, brown, inermous ſtems, from the bottom, five or ſix feet high; very large ſimple palmated leaves; and the ſhoots terminated by many large purpliſh flowers, ſucceeded by ſmall red fruit; rarely ripening in England.

This plant is very ornamental, having beautiful large foliage, and numerous large flowers; continuing near two months, which renders it worthy of admittance in every ſhrubbery plantation; where it will multiply exceedingly by ſuckers ſent up annually from the root all around.

[3]RUBUS *Occidentalis*.

*Occidental, or Canada Black-fruited Raſpberry*.] Riſes with erect, ligneous, prickly, purpliſh ſtems four or five feet high; ternate leaves, hoary underneath, having taper foot-ſtalks; and the ſhoots terminated by cluſters of ſmall flowers, ſucceeded by ſmall black fruit.

*Trailing Shrubby Kinds.*

Conſiſts of the common Bramble, and varities; and ſome others of the Bramble kind, being moſtly ſhrubby trailers, of hardy growth, and deciduous.

[4]RUBUS *Fruticoſus*.

*Shrubby Rubus, or common Bramble of the Hedges*.] Hath very long, ſhrubby, trailing, channelled, greeniſh, and reddiſh ſtalks, cloſely armed with ſtrong crooked aculi; digitated, five- and three-lobed leaves, having prickly petioles; and all the lateral ſhoots terminated by cluſters of white flowers, ſucceeded by ripe black-berries in autumn.

*Varieties*.] Common Bramble, or Blackberry plant of the hedges—double bloſſomed Bramble of the gardens—white-fruited Bramble — inermous, or thornleſs Bramble — cut-leaved Bramble—ſtriped-leaved Bramble.

All theſe varieties are of trailing growth, with very long, luxuriant, durable ſhoots. The common wild bramble, or Blackberry plant, being the parent ſpecies, which grows wild on banks, and in field-hedges, almoſt every where; ſo is ſeldom admitted in gardens, except a plant or two for variety among the climbing-tribe, or where wilds or thickets are intended. But the double-bloſſomed Bramble, white-berried, and thornleſs kind, &c. being curioſities, they claim admittance in every ſhrubbery; and may be trained both as climbers, allowing them ſupport of buſhes or ſtakes; or may be trained as ſtandard ſhrubs, if ſtaked, and trimmed down at top, to cauſe them to ſhoot out into buſhy heads, continuing to reduce the rambling ſhoots as occaſion requires, to keep the head to the deſired form; and where any part of a garden is deſigned to repreſent wilds, &c. ſome plants of all the varieties ſhould be introduced, and ſuffered to ſhoot and run according to the courſe of nature.

[5]RUBUS *Cæſius*.

*Blue-berried Bramble, or Dewberry-buſh*.] Hath long, taper, ſlender, trailing, prickly-ſtalks; ternate, almoſt naked leaves; and whitiſh flowers at the ſides and ends of the branches, ſucceeded by large ſky-blue fruit in autumn.

It grows naturally in moiſt ſituations in England; and is ſometimes admitted into gardens for variety.

[6]RUBUS *Hiſpidus*.

*Hiſpid Canada Bramble*.] Hath long, ligneous, procumbent, hiſpid ſtalks; ternate, naked, cut, ſerrated leaves, with hiſpid foot-ſtalks.

*Herbaceous Perennial Kinds.*

Compriſes two dwarfiſh, ſomewhat herbaceous, durable plants of erect growth, riſing but a few inches high.

[7]RUBUS *Chamæmorus*.

*Chamæmorus Dwarf Mulberry, or Cloud-berry*.] Riſes with ſlender inermous ſtalks, ſix or eight inches high; garniſhed with two ſimple, lobated leaves; and the ſtalks terminated by one purple flower, ſucceeded by a ſmall black fruit, reſembling a mulberry.

It grows naturally in England and Scotland, &c. in high mooriſh ſituations.

[8]RUBUS *Arcticus*.

*Northern Rubus, or Dwarf Siberian Bramble*.] Riſes with erect inermous ſtalks, but three or four inches high; ternate leaves, and the ſtalks terminated by purple flowers, ſingly; ſucceeded by ſmall red fruit, having the ſmell and taſte of ſtrawberries.

All

All the above eight ſpecies of *Rubus*, are for the general part deciduous, the leaves coming out in the ſpring, and fall off in the winter; and they flower generally in June and July. The flowers are compoſed each of five roundiſh petals and numerous ſtamina, ſucceeded by roundiſh compound berries, each being compoſed of many ſmall acini of a pulpy juicy nature;—ripening from July till October, in different ſorts: remarking thoſe of the *Rubus Idæus* and varieties, are the principal ſorts for general uſe.

The plants of all the ſpecies are very hardy; the ligneous and ſhrubby kinds in particular, will proſper almoſt any where. But the herbaceous kinds, being naturally reſidents of mooriſh or fenny places, require ſome ſimilar ſituations when cultivated in gardens.

With reſpect to the merit of all the ſorts as garden plants; obſerve as follows.

The firſt ſpecies: *Common Raſpberry*, and varieties, demand culture in every garden for their fruit; particularly the common red kind, white ſort, and twice-bearing raſpberry; all of which are great bearers: but for the general plantations, chuſe principally the common red and the white kind, as being generally the greateſt bearers of all. Planting alſo a ſhare of the twice-bearing ſort, both as a curioſity, and for the ſake of its autumnal crops of fruit, which in favourable ſeaſons, ripen in tolerable perfection; obſerving to allow all the ſorts ſome open expoſure in the kitchen-garden, though they will proſper in almoſt any ſituation. It is however adviſeable to plant the general plantations moſtly in a free expoſure in rows, a yard and half aſunder: ſome plants may alſo be diſpoſed ſingly about the borders or ſhrubbery clumps, for variety: and, in all the modes of planting, they ſhould generally be kept to ſingle bunches of four or five ſtems on each root or ſtock. See their *Propagation and general Culture.*

The other ſeven ſpecies, are conſidered as plants of variety, for hardy plantations in the ſhrubbery: ſome of which are alſo very ornamental flowering plants; particularly the Virginian flowering Raſpberry, and the double bloſſomed Bramble; both of which, having great merit as furniture for ornamental compartments: and the white-berried Bramble is a great curioſity. All the other ſpecies and varieties ſerve to diverſify large collections.

*Propagation and Culture of the common Raſpberry and Varieties.*

The propagation of the common Raſpberry and varieties, is expeditiouſly effected by ſuckers from the root; all the ſorts ſending up great numbers on all ſides annually growing from three to four or five feet height the ſame year, and form proper plants by autumn or winter following, for tranſplanting for new plantations, and will all bear fruit the following ſummer.

Therefore, any time from October till March, in open weather, having recourſe to ſome good plantation of Raſpberry plants of ſome ſtanding; and proceed to take up a ſufficient quantity of laſt ſummer's ſuckers, that are ſituated around the outſide of the ſtools, or main ſtock, raiſing them carefully with plenty of fibres; and, having obtained a proper quantity, then let them be trimmed for planting, ſhortening any long ſtraggling roots, and, if any naked woody parts of the root of the old ſtool adhere, cut it off; obſerving at the ſame time, if one or more buds appear near the root, they being the embryo of future ſhoots, muſt be very carefully preſerved: and ſhorten each ſucker at top, to about two or three feet long, or more according to their ſtrength, they are then ready for planting: having previous to this, choſen an open ſpot of good ground, as before adviſed; and having well dunged and trenched it one or two ſpades deep, proceed to put in the plants above prepared, as ſoon as poſſible.

With a line mark out the diſtances for the plants, in rows, a yard and half diſtance, and a yard aſunder in the rows, which is conſiderably more than is commonly allowed: but, if planted much cloſer, the plants, as they ſend up numerous ſuckers in ſummer, would grow ſo cloſe, as to form quite a thicket, ſo as to exclude the due influence of ſun and air from the fruit, as well as to render it troubleſome to get between the rows, occaſionally to gather the produce; therefore allow the above diſtances: and having drawn lines accordingly, proceed with a ſpade, and open ſmall apertures in the ground, cloſe along the line, one for each plant, a yard aſunder, planting them as you go on, one in each hole erectly, covering in the roots properly with the earth, treading it moderately firm, to preſerve the upright poſition of the plants: obſerving, if the planting is performed late in the ſpring, it is adviſeable to give a good

watering, and repeat it occaſionally, till the plants have ſtruck freſh root.

Having thus made a plantation of Raſpberries, they will readily take root, and ſet to growing freely in the ſpring, they being naturally of a free growth, and moſt of them will bear tolerably the firſt ſummer; but in the ſecond they will bear a full crop in the utmoſt perfection.

As to their general culture, it conſiſts of the following operations — Keeping them clean from weeds all ſummer by broad-hoeing; giving them an annual dreſſing in autumn or winter, conſiſting of breaking down the decayed ſtems that bore the preceding ſummer; thinning the young ſucceſſion bearers; clearing away all intermediate ſuckers between thoſe of the main ſtocks, and then dig the ground between the rows of plants; obſerving the following particulars of the method of performing the operations of their annual dreſſing.

Previous to the above-mentioned annual dreſſing of Raſpberries, obſerve, as we before noticed of their mode of bearing, that as they produce a freſh ſupply of ſhoots or ſuckers every year from the bottom for bearing, thoſe produced one year, bear the next, then totally decay to the root in winter, there being at the ſame time a ſucceſſion of laſt ſummers ſhoots, on the ſame ſtools, for bearing the ſummer following: therefore, in the annual dreſſing, which may be performed any time from October till March, firſt proceed to clear out all the decayed ſtems, being laſt ſummer's bearers, breaking them down cloſe to the bottom; then examine the ſupply of young ſhoots for next year's bearing, ſelecting three or four, but not more than five or ſix of the ſtrongeſt on each ſtool, cutting all the others away cloſe to the ground: likewiſe draw up all ſtraggling ſuckers between the main plants; all of which remaining plants, ſhould be ſhortened according to their ſtrength, cutting them generally a little below the bend at top of the ſhoots, to about three or four feet in length, both to render them more robuſt, to ſupport themſelves more firmly upright in ſummer, and to promote a ſtronger ſupply of laterals for flowering and fruiting. Or if you ſhould chuſe to leave them longer, or at full length, thoſe of each ſtock may be plaited together, in order to ſupport each other erect: then having cleared away all the rubbiſh, let the ground between the rows be neatly dug one ſpade deep. As you proceed in digging, clear out all the roots of ſtraggling ſuckers between the rows, &c. leaving the earth cloſe and level about and between all the plants: thus far is the whole neceſſary culture of a plantation of Raſpberries, which muſt always be repeated annually, at the ſeaſons abovementioned.

Allow them a little manure of rotten dung once every other year, applying it in the winter dreſſing and dig it in one ſpade deep; it will add vigour to the plants, ſo as to continue them producing fruit in great perfection ſeveral years.

However, it is adviſeable to make a freſh plantation every four or five years, in a freſh ſpot of ground, as after that period of time, the plants, although they may continue ſhooting with tolerable vigour, yet they are apt to be leſs fruitful, and the fruit ſmaller than in younger plantations in a freſh prepared piece of ground.

*Propagation, &c. of the other Species.*

The propagation of the other ſpecies of Raſpberries, Bramble, &c. is by ſuckers, layers, cuttings, dividing the roots, &c. and the two herbaceous kinds alſo by ſeed.

By Suckers.——All the Raſpberry kinds in particular ſend up many ſuckers annually, and by which they may be propagated in great abundance, taking them up in autumn, winter, or ſpring, with roots, and the ſtrongeſt may be planted at once in the ſhrubbery, and the others in nurſery rows for a year or two, or till wanted.

By Layers.——All the Bramble kind are eaſily propagated by this method, laying the ſhoots almoſt any time, they will readily emit roots at every joint, and be fit to tranſplant in autumn following.

By Cuttings.——By this method alſo may the Brambles be propagated in autumn; cutting off ſome of the younger ſhoots, and divide them into lengths a foot long, and plant them in a ſhady border, many of them will ſtrike.

By dividing the Roots.——Any of the Raſpberry kind, &c. and the herbaceous ſpecies, when encreaſed into large bunches, may be divided or ſlipped into ſeveral diſtinct ſets, and plant them ſeparately.

By Seed.——As the two herbaceous ſpecies do not always encreaſe freely by roots in gardens, therefore, in default of which, procure ſome of the ripe fruit in autumn, or as ſoon as poſſible; and chuſing ſome moiſt ſituation,

either

either in a nurſery, or where you deſign the plants to remain, ſow the ſeed half an inch deep; obſerving, if ſome of the plants are permitted to remain where raiſed, they will probably be more proſperous than ſuch as are tranſplanted.

RUDBECKIA, Dwarf Amerian Sunflower.

This genus comprehends ſeveral herbaceous flowery perennials, and a biennial, ſerving to embelliſh the pleaſure ground; riſing with annual ſtalks, from about half a yard to ſix or eight feet high, garniſhed with oval, ſpear-ſhaped, and divided leaves; and the ſtalks terminated by large compound radiated flowers.

Claſs and order, *Syngeneſia Polygamia Fruſtanea.*

*Characters.*] CALIX, a general calix, compoſed of two orders of broad, plane, ſhort, ſcaly leaves, containing many florets.—COROLLA, is compound, and radiated; conſiſting of many tubular, hermaphrodite florets in the diſc, and ſpear-ſhaped, flat, barren florets in the radius.—STAMINA, five very ſhort hair-like filaments, having cylindric antheræ.—PISTILLUM, a tetragonous germen, filiforme ſtyle, and bipartite revolute ſtigma.—PERICARPIUM, none; the hermaphrodite florets, ſucceed each to one oblong ſeed, crowned with down, which is quadridented, and the ſeeds lodged in a conic chaffy receptacle.

There are ſix ſpecies, five of them herbaceous perennials, and the ſixth a biennial, all natives of North America; but grow freely here in our gardens, in any open compartments.

*Perennial Kinds.*

[1]RUDBECKIA *Hirta.*

*Hairy Dwarf American Sunflower.*] Riſes with upright ſtalks, a foot and half high; oval-ſpattle-ſhaped, undivided, triple-nervous leaves; and the ſtems dividing upward into many long pedunculi, terminated each by one large radiated yellow flower, having a prominent purple diſc, and the petals of the radius emarginated.

[2]RUDBECKIA *Purpurea.*

*Purple Dwarf Carolina Sunflower.*] Riſes with upirght ſtalks about two feet high; oval-lanceolate, undivided, alternate leaves; and the ſtalks and branches terminated by purple flowers, ſingly; having the petals of the radius bifid.

*Varieties.*] With a dark-purple diſc, and pale red radius—with long purple petals in the radius—with broad petals in the radius.

[3]RUDBECKIA *Laciniata.*

*Laciniated, or jagged-leaved Tall Virginian Rudbeckia.*] Riſes with upright ſtems, ſix or eight feet high; large, compound, moſtly, five-lobed leaves, having the lobes deeply laciniated, or jagged; and the ſtems and branches terminated by radiated yellow flowers.

*Varieties.*] Broad-leaved—narrow leaved—purple ſtalked, with digitated leaves, &c.

[4]RUDBECKIA *Anguſtifolia.*

*Narrow-leaved Dwarf Virginia Sunflower.*] Riſes with upright firm ſtems, two or three feet high, or more; long, linear, or very narrow, entire, oppoſite leaves; and the ſtalks terminated by yellow-rayed flowers, having a dark-red diſc.

[5]RUDBECKIA *Oppoſitifolia.*

*Oppoſite-leaved Dwarf Virginia Sunflower.*] Riſes with upright ſtalks two or three feet high; lanceolate-oval, ſerrated, oppoſite leaves, and wholly yellow flowers, having the petals of the radius bifid.

*Biennial Kind.*

[6]RUBBECKIA *Triloba.*

*Three-lobed Virginia Rudbeckia.*] Hath ſpatula ſhaped, trilobated, radical leaves; amidſt them upright ſtems, garniſhed alſo with three-lobed leaves; but thoſe on the branches are undivided; and yellow-rayed flowers, having dark-purple diſcs.

All theſe ſix ſpecies flower here annually in July and Auguſt, often continuing in ſucceſſion till September or October; and in ſome ſorts, are ſometimes ſucceeded by ripe ſeeds in autumn, particularly the firſt and laſt ſpecies.

They are all tolerably hardy: the firſt five ſpecies are moſtly perennial in root, but annual in ſtalk; though the fourth and fifth ſorts have often a tendency to a biennial nature; however, the ſixth ſort is perfectly biennial; all of which ſend up their flower-ſtems in the ſpring, which generally branch out upward, the branches terminated by long pedunculi, each crowned by one moderately-large radiated flower, nearly reſembling the common ſunflower, but ſmaller; have generally a prominent, ſomewhat pyramidal diſc, and a ſpreading radius; and are all very conſpicuous, even at a diſtance.

All the ſpecies are proper furniture for the open compartments of the pleaſure-ground, as being very ſhewy plants when in bloom; and produce many flowers in ſucceſſion, two or

three months; effecting a good ornamental appearance.

Obſerve to allow moſt of the ſorts a lightiſh, dry ſoil, and ſomewhat ſheltered ſituation; remarking however, the third ſort in particular *(Rudbeckia laciniata)* will ſucceed almoſt any where.

*Method of Propagation, &c.*

Their propagation is by off-ſets, and parting the roots; and by ſeeds.

By off-ſets, and parting the roots.——This is practicable for all the perennial kinds; but the firſt ſort in particular generally reſolves itſelf into ſeveral off-ſet heads, at the crown of the root, which being ſlipped in autumn, or early in ſpring, each will form a proper plant. Moſt of the other perennial ſorts encreaſe by the root, though the *Rubeckia Purpurea* multiply rather more ſparingly than the others; however, the propagation of all the ſorts may be effected leſs or more by parting the roots in autumn, when the ſtalks decay.

Obſerve, as ſome of the perennial kinds ſometimes diſcover a tendency to go off in three or four years, it is eligible to continue propagating them frequently to keep up a ſtock of vigorous plants. Some ſorts being alſo ſometimes inclinable to a biennial nature, are apt to decay ſoon after they have flowered, without encreaſing at root, for future propagation, particularly the fourth and fifth ſorts; to prevent which, it is proper to cut down ſome of the flower-ſtems of ſuch kinds in May, or early in June, which will encourage their multiplying more effectually by root off-ſets, fit for ſlipping next autumn.

By Seed.—All the ſorts may be raiſed plentifully from ſeed; but the biennial ſorts in particular muſt always be raiſed from ſeed annually; likewiſe, ſuch of perennials as are biennially inclined; ſowing the ſeeds in April, in a border of light earth, and rake them in; and when the plants are two or three inches high, prick them out in nurſery-rows, till autumn; then tranſplanted where they are finally to remain.

RUMEX, Dock; comprehending the *Acetoſa*, or Sorrel, &c.

This genus furniſhes herbaceous perennials for the kitchen-garden, and pleaſure-ground, and a ligneous ever-green for the green-houſe; are garniſhed with ſimple, oblong, ſaggitated, and roundiſh, heart-ſhaped leaves; and ſpikes of ſmall tripetalous flowers of no beauty.

Claſs and order, *Hexandria Trigynia.*

*Characters.*] CALIX, three obtuſe, reflexed, permanent leaves.—COROLLA, three ſmall oval, connivent, permanent petals, like the leaves of the calix, but larger.—STAMINA, ſix very ſhort capillary filaments, having erect didymous antheræ.—PISTILLUM, a turbinated triquetrous germen, three hair-like reflexed ſtyles, and large laciniated ſtigmas.——PERICARPIUM, none; a ſingle triquetrous ſeed, lodged in the permanent corolla.

To this genus, *Rumex*, is added the *Acetoſa*, or Sorrel, formerly conſidered as a diſtinct genus; conſiſting of ſeveral ſpecies, but now all ranged as ſpecies of *Rumex*, which comprehends in the whole about twenty-ſix herbaceous, and one woody ſpecies; eight or ten of the former grow wild in this country, and the others are of foreign growth; but there are not more than four or five that have merit for garden culture; conſiſting of four hardy herbaceous perennials, and one tender woody plant.

*Hardy Herbaceous Kinds.*

Under this head is compriſed the common culinary Sorrels for the kitchen-garden; the Patience Dock, &c. and Bloody Dock, for medical purpoſes, and variety; all of which are hardy perennials.

The two firſt ſorts are of the Sorrel kind.

[1]RUMEX *Acetoſa.*

*Acetoſa, or common Arrow-pointed Meadow Sorrel.*] Hath fibrated roots, crowned by a large tuft of oblong-ſaggittated leaves; and amongſt them upright ſtems a foot or more high, terminated by ſpikes of ſmall herbaceous dioecious flowers, ſucceeded by ripe ſeeds in autumn.

*Varieties.*] Common Meadow-ſorrel.——Barren Northern Sorrel, which rarely running to ſeed continues almoſt always in leaf for uſe—broad-leaved Mountain Sorrel.

The Common Sorrel is a natural reſident of our meadows and paſtures; but has been long admitted an inhabitant of the gardens as a ſoup-herb; and is the moſt commonly cultivated Sorrel for general uſe, both as a valuable acid culinary herb, and for medicinal purpoſes; its leaves being the uſeful part, which by garden culture obtain a fine large ſize.

The plants are eaſily raiſed from ſeed, and by parting the roots. See their *Propagation*, &c.

[2]RUMEX *Scutatus.*

*Shield-ſhaped Rumex, Round-leaved, or French Sorrel.*] Hath a creeping root crowned with

with a tuft of large roundiſh, heart-ſhaped, haſtated leaves; rambling ſhoots, and the flower ſtems terminated by ſpikes of ſmall hermaphrodite flowers, ſucceeded by ſeeds in autumn.

This ſpecies of Sorrel is by many preferred to the common *Acetoſa*, or Meadow Sorrel; the leaves being larger, and thought to poſſeſs a more agreeable acid reliſh.

The above two ſpecies of Sorrel and varieties are all of the culinary kind; any, or all of which may be raiſed for general uſe; and may all, but the Barren Sorrel, be propagated by ſeed: all the ſorts alſo by parting the roots, planting them in any bed or border, ten or twelve inches aſunder, and they will furniſh leaves moſt part of the year.

[3]RUMEX *Patientia.*

*Patientia, or Patience Dock, or Monks Rhubarb.*] Hath a large, thick, divided, deeply-ſtriking root, yellow within, crowned with large, oblong, heart-ſhaped leaves, a foot long, on very thick reddiſh foot-ſtalks; upright ſtrong ſtems, dividing and branching three or four feet high; having the branches terminated by cloſe erect ſpikes of whitiſh hermaphrodite flowers, and with entire valves, one being graniferous.

*Variety* ] Round-leaved Alpine Patience Dock; commonly called Monks Rhubarb.

This ſpecies and variety are natives of Italy and the Alps; are retained in our gardens both as medical plants, and to effect variety, alſo formerly for culinary uſes; they ſhoot up into ſtalks annually in the ſpring, flower in May, and ripen ſeeds in autumn.

[4]RUMEX *Sanguineus.*

*Bloody Dock.*] Hath long downright roots, erect red-ſtalks, two or three feet high; heart-formed lanceolate leaves, having blood-red veins, and many red ſpots; the ſtalks terminated by ſpikes of hermaphrodite flowers, and with entire valves, one being graniferous.

This is retained in many gardens for the ſake of variety.

*Woody Kind for the Green houſe.*

[5]RUMEX *Lunaria.*

*Tree-like Rumex, commonly called Tree Sorrel.*] Riſes with a woody, tree-like, ſmooth ſtem, branching eight or ten feet high; garniſhed with roundiſh heart-ſhaped leaves; the branches terminated by looſe panicles of greeniſh hermaphrodite flowers, and with ſmooth valves.

This is an exotic from the Canary Iſlands, and is retained in our gardens to encreaſe the variety in the green-houſe collection.

The above five ſpecies are principally all the ſorts of *Rumex*, commonly cultivated in the Engliſh gardens; the four herbaceous kinds are perennial in root, and annual in ſtalks, and hardy enough to ſucceed in any open ſituation; and the woody kind is durable both in root and ſtem, &c. and is tender, requiring ſhelter of a green-houſe, in winter. They flower generally in June or July; the flowers are ſmall and tripetalous, generally terminating the ſtalks and branches in ſpikes, but are not ornamental; and are ſucceeded by ripe ſeeds in autumn.

Their merit as garden plants is, all the herbaceous Sorrel kinds, are eminent ſoup herbs for culture in the kitchen-garden, as aforeſaid: the *Rumex Patientia*, as a medical plant; alſo, together with the *Rumex Sanguineus*, is often employed for variety in the pleaſure-ground; and the *Tree Sorrel* being tender, muſt be potted and placed among the green-houſe exotics.

*Propagation and Culture.*

Moſt of the herbaceous culinary Sorrels are raiſed from ſeed, and by parting the roots.

By Seed.—The common Sorrel, and round-leaved kind may be raiſed abundantly by ſeed in the ſpring; but the common Sorrel in particular ſhould be generally raiſed by this method, as the other propagates exceedingly by its repent roots, &c. However, both ſorts may be ſowed in March, in any bed or border, broad caſt, and rake them in evenly, they will ſoon come up; obſerving, if the plants riſe too thick, thin them moderately; and after being a little advanced in growth in ſummer, plant out a quantity of the ſtouteſt in moiſt weather, in ſome bed or border in rows, the common ſort and varieties about eight or nine inches aſunder, and the other a foot at leaſt, giving proper waterings, and they will grow freely, and be fit to cut for uſe the ſame ſummer and autumn, &c. and continue ſeveral years.

Obſerve however, of the common Sorrel in particular, that as ſeedling plants of one or two years old, generally produce larger leaves than older plants, it may be eligible to raiſe a freſh ſupply of ſeedlings annually, or at leaſt every other year.

By parting the Roots.——All the ſorts may be propagated by this method, but the Round-leaved French Sorrel in particular increaſes exceedingly by running at the root; and the

Barren

Barren Sorrel, rarely producing ſeed, is propagated principally only by parting the roots. However, any of the ſorts may be eaſily increaſed by this method, which may be effected either in autumn or ſpring, though I ſhould rather preſer the ſpring ſeaſon, about the beginning or middle of March; either ſlipping off a quantity of off ſets from the old plants as they ſtand, by aſſiſtance of a knife or ſpade; or take ſome of them wholly up, and divide them into ſeveral ſlips, planting them in rows a foot diſtance, and give directly a good watering, they will expeditiouſly take root, aſſume a free growth, and furniſh plenty of leaves for uſe all ſummer and autumn, &c.

As to the culture of theſe plants, very little is required more than the neceſſary care of keeping them clean from weeds; and in ſummer, when they run to ſtalk, it is proper to cut them down cloſe to encourage a more plentiful ſupply of large leaves from the bottom; likewiſe, when the leaves have become very rank, cut them down occaſionally towards the latter part of ſummer, that the roots may ſend up a good ſupply of freſh leaves for autumn, and winter ſervice.

The *Patientia* and Bloody Dock, are alſo raiſed by ſeed, and the former likewiſe by roots.

By Seed.—In autumn, or early in ſpring, ſow the ſeed in a bed of light earth, and rake it in; and when the plants are come up three inches high, thin out a quantity, and plant them either in nurſery-rows a foot diſtance, or at once where they are to remain.

By Roots.—The Patience Dock, and variety, encreaſe by off-ſets from the root, which being ſlipped in autumn, and the ſlips directly planted, they will readily grow.

And the *Rumex Lunaria*, or *Tree Sorrel*, is propagated eaſily by cuttings of the young ſhoots in ſpring and ſummer; if performed in ſpring, plant them in pots, and plunge them in a hot-bed, they will very ſoon emit roots; but in ſummer, they will ſucceed without aid of artificial heat, planted either in pots, or in a border of common earth, and occaſionally ſhaded and watered, many of them will ſtrike and be well rooted by autumn.

RUSCUS, Butchers Broom, and Alexandrian Laurel.

Conſiſts of low ſhrubby, and under-ſhrubby ever-greens, for the ſhrubbery and greenhouſe collection; riſing ſome three or four feet high, others ſcarcely a foot; garniſhed with ſmalliſh, oblong, and lanceolate leaves, ſome prickly, others ſmooth, from one to three inches long, and from half an inch to an inch broad, remaining all the year; and dioecious apetalous flowers, produced in moſt ſorts, on the ſurface, and margin of the leaves, and in ſome at the ends of the branches.

Claſs and order, *Dioecia Syngeneſia*.

*Characters.*] CALIX, Dioecious flowers, having ſpreading cups compoſed of ſix oval convex leaves.—COROLLA, no petals, but an oval erect nectarium, the ſize of the calix, open at the mouth.—STAMINA, no filaments, but three ſpreading antheræ, ſitting on the nectarium, and join at the baſe.—PISTILLUM, an oblong-oval germen, hid within the nectarium, a cylindric ſtyle, crowned by an obtuſe ſtigma, ſtanding above the mouth of the nectarium.—PERICARPIUM, a round, or globular trilocular berry, having two round ſeeds.

This genus conſiſts of five ſpecies, three or four of which are hardy for any open plantations; and the others tender, requiring ſhelter of a green-houſe in winter.

*Hardy Kinds.*

Under this head is compriſed the common Butchers Broom—*Hypogloſſum*, or Tongued Laurel—and Alexandrian Laurel; all of which are ſhrubby ever-greens of hardy growth.

1 RUSCUS *Aculeatus.*

*Prickly Ruſcus, Common Butchers Broom, or Knee-Holly.*] Hath a thick, fibrated, creeping, deeply-ſtriking, white root; ſeveral erect, ſhrubby, tough, green ſtems, two or three feet high, cloſely garniſhed with ſmall, oval, ſtiff, dark-green leaves, alternately, terminating in prickly points; and ſmall, purpliſh flowers, ſituated on the upper ſurface of the leaves, ſucceeded in the female plants, by large red berries, ripening in winter.

This ſpecies grows abundantly in England, &c. in woods, and is introduced in many gardens, in wilderneſs, and ſhrubbery plantations for variety.

Great quantities of the young buſhy plants of this ſpecies are brought to London in winter for ſale; they being collected in the neighbouring woods, by the herb people, taking them up with a little ball of earth about the roots, wrapping the ball up with moſs, and in that manner hawk them about the ſtreets; and the citizens buy them to plant in pots of ſand, to adorn rooms, where they will remain green a long time. It is alſo in much requeſt among

among the butchers, for ſcrubbing brooms; the branches being tied in bundles, forming a ſort of broom, or beſom; and with which they ſcrub their chopping-blocks. Hence the name Butchers Broom.

[2]Ruscus *Hypophyllum.*

*Hypophyllum, or Broad-leaved Italian Butchers Broom.*] Hath thick, knotty, long-fibrated roots; many ligneous, pliable, tough, green ſtems, two or three feet high; oblong, oval, ſtiff, ſhining-green leaves, placed alternately, and bearing flowers on their under ſurface; ſucceeded, in the female plants, by ſmall red berries, ripening in winter.

[3]Ruscus *Hypogloſſum.*

*Hypogloſſum, or Tongued Ruſcus, commonly called Tongue upon Tongue Laurel.*] Hath thick fibrey roots; many ligneous, ſlender, pliable, green ſtems, ten or twelve inches high; long ſpear-ſhaped leaves, each having a ſmaller leaf, like a tongue, iſſuing from its upper ſurface, and from the bottom of which are produced ſmall yellowiſh flowers, ſucceeded by large red berries, ripening in winter.

It is a native of mountainous parts of Hungary and Italy.

[4]Ruscus *Racemoſus.*

*Racemoſe flowered Ruſcus, or Alexandrian Bay, commonly called Alexandrian Laurel.*] Hath thick, long, fibrey, whitiſh roots; many ſhrubby, ſmooth, very pliable, ſhining-green ſtems, four or five feet high, producing branches alternate-ways; garniſhed with oblong-lanceolate, ſhining-green leaves; and yellowiſh hermaphrodite flowers, terminating the branches in racemous cluſters, ſucceeded by large red berries, ripening in winter.

This ſpecies having the name of Bay, and Laurel, and being of a fine pliant growth, is ſuppoſed to be the plant uſed by the ancients for compoſing wreaths to crown their victors, and eminent poets.

*Variety.*] With red-flowers.

The above four hardy ſpecies grow freely in any of the ſhrubbery plantations; and multiply exceedingly by off-ſet ſuckers from the bottom.

*Tender Kind for the Green-houſe.*

[5]Ruscus *Androgynus.*

*Androgynous Canary Ruſcus.*] Riſes with ſhrubby, pliant ſtems, five or ſix feet high, producing many ſide branches; garniſhed with oblong, ſtiff leaves; bearing ſmall white flowers on their edges, ſucceeded by reddiſh berries.

All the above five ſpecies of *Ruſcus* flower abundantly in June and July; four of which producing their flowers wholly upon the leaves, exhibit a curious ſingularity; and the *Ruſcus Androgynus* in particular, which having its flowers cloſely ſet all along the edges of the leaves, effect a ſingular and beautiful appearance; and the hardy ſorts are often ſucceeded by ripe fruit in our gardens in winter.

All the hardy ſorts are proper furniture for the verges of ſhrubberies, or any cloſe plantations, as they thrive under the drip of trees, and will remain green the year round, and increaſe the variety of thoſe compartments.

The tender ſort requires ſhelter of a green-houſe in winter, ſo muſt be planted in pots and managed as other ſhrubby exotics of that department.

The propagation of all the ſorts is very eaſy, as they increaſe very faſt by the roots, which ſending up numerous ſtalks or ſuckers, they may be taken up in autumn, winter, or ſpring, in open weather, and divided into many ſeparate ſets, each forming a proper plant; though they need not be divided too ſmall, unleſs where a great increaſe is required, planting the largeſt at once where they are to remain, and the ſmalleſt in nurſery-rows, &c. each plant will ſoon encreaſe by off-ſets, and aſſume a buſhy growth.

They may alſo be raiſed from ſeeds, though not expeditiouſly, for the ſeed often remains in the ground till the ſecond ſpring; ſow that of the hardy ſorts in any bed or border an inch deep; and the tender kind in pots, and placed under ſhelter, in cold weather; and when the plants are a year old, it is proper in March to prick them out, the hardy ſorts in nurſery-beds, for two or three years; and the tender ſort in pots.

RUTA, Rue.

It conſiſts principally of under-ſhrubby plants for the kitchen-garden and pleaſure-ground; adorned with many-lobed leaves, and ſmall tetrapetalous flowers, growing in bunches.

Claſs and order, *Decandria Monogynia.*

*Characters.*] Calix, is ſhort, five-parted, and permanent.——Corolla, four-oval, ſpreading petals.—Stamina, ten awl-ſhaped patent filaments, having ſhort erect antheræ.—Pistillum, a gibbous, croſs-furrowed germen, having ten punctures, an erect ſtyle, and ſimple ſtigma.—Pericarpium, a gibbous, five-lobed, quinquelocular, capſule, opening

opening in five parts at top, having many reniforme, angular, rough ſeeds.

There are three ſpecies, one of which only a ſhrubby, perennial; is common to the Engliſh gardens, comprehending ſome varities, valued chiefly as medical plants, and ſometimes to diverſify the ſhrubbery.

The ſpecies is,

RUTA *Graveolens.*

*Graveolent Ruta, or common Garden Rue.*] Riſes with a ſhrubby, very branchy ſtem, four or five feet high, forming a buſhy head; cloſely garniſhed with decompound, many-lobed, ſtrong-ſcented grey leaves; and the branches terminated by bunches of yellow flowers, having torn petals, and the lateral flowers quadrifid, ſucceeded by ripe ſeeds in autumn.

*Varieties.*] Common broad-leaved garden Rue—narrow-leaved Rue—broadeſt-leaved Aleppo Rue—narrow-leaved Aleppo Rue—variagated-leaved Rue.

They all flower in June, and ripen plenty of ſeed in autumn, particularly the common ſorts.

All theſe varieties of this ſpecies are hardy enough to ſucceed in the open ground, tho' the two Aleppo Rues ſhould have a ſheltered ſituation, and dry ſoil; and it is adviſeable to pot ſome of thoſe two ſorts to move, to ſhelter of a frame, or green houſe, in winter; the variagated kind ſhould likewiſe have a dry, poor ſoil, otherwiſe is apt to become vigorous, and loſe its variegations.

As to their uſes in gardening: the common broad and narrow-leaved Rues, are eſteemed principally as medicinal plants, and as ſuch merit culture in every garden, allowing them generally a dry ſoil, and may be raiſed both by ſeed, and by ſlips or cuttings; and afterwards planted out either ſingly about the borders; or where large quantities are wanted, in rows two feet aſunder, and a foot and half in the lines; but about London, where great quantities are raiſed for market, they commonly plant them in four-feet wide beds, in rows a foot aſunder; which, after having one or two years growth, and formed into little buſhy plants, are taken up in ſpring and ſummer, with balls, and carried to the markets for ſale; they likewiſe pot many of them, both of the plain green and variegated kind, which are alſo ready ſale in market, to place, to adorn court-yards, balconies, &c.—But all the varieties may alſo be employed in the ſhrubbery compartments, in a dry ſituation, where they will effect an agreeable diverſity, both in foliage and flowers.

The propagation of all the varieties is by ſeed, and by ſlips and cuttings.

By Seed.——The common Rue in particular may be raiſed plentifully by ſeed in the open ground; ſowed in March or April, on a bed of light earth, and rake it in; they will ſoon come up, which, when two or three inches high, ſhould be planted out in nurſery-rows, and watered till freſh rooted.

From the ſcattered or ſelf-ſowed ſeeds of the common Rue, many young plants often riſe in autumn and ſpring.

By Slips or Cuttings.——This is the moſt expeditious method of propagation for all the ſorts, for every ſlip or cutting of the branches will readily grow; and is the only method of propagation, by which we can continue the different varieties diſtinct; therefore in ſpring, any time in March or April, ſlip or cut off a quantity of the young ſhoots, ſix or eight inches long, and plant them in a ſhady border, in rows half a foot aſunder, giving a good watering, and repeat it occaſionally, they will ſoon emit roots below, and ſhoots at top, ſo as to form little buſhy plants by autumn.

# S.

SACCHARUM, Sugar-cane, or Sacchariferous Reed.

The plants of this genus are tall-growing tender perennials, of the arundinaceous tribe, natives of the Indies, and retained here in our ſtoves for variety; one of which is a moſt valuable plant, as from the juice of its ſtalks is prepared the various ſorts of ſugar; they riſing with erect ſtrong ſtems, eight or ten feet high, adorned with very long leaves, and terminated by large panicles, and ſpikes of numerous bivalvous flowers.

Claſs and order, *Triandria Digynia.*

*Characters.*] CALIX, none, but a woolly-down incloſes each flower.——COROLLA, is bivalve; having too oblong-lanceolate, acuminate, concave valves.— STAMINA, three capillary filaments, as long as the valves, and oblongiſh antheræ.—PISTILLUM, a ſubulate germen, two cirrhoſe ſtyles, and ſimple ſtigmas.——PERICARPIUM, none, one narrow ſharp-pointed ſeed to each floret, inveſted by the valves.

The ſpecies are,

¹SACCHARUM *Officinarum.*

*Common Sugar Cane.*] Hath a long thick-jointed, fibrated, ſucculent root; ſending up ſeveral upright, round, jointed ſtems, from ſix or eight to ten feet high, or more, abounding with a pithy ſaccharine juice; having at each joint large oblong leaves, three or four feet long, the baſe embracing the ſtalk a conſiderable way up; and the ſtalks terminated by very large panicles of numerous ſmall flowers.

This ſpecies is the true Sacchariferous Cane, from which the ſugary juice is expreſſed, which being boiled and refined, becomes that well known uſeful ſubſtance called Sugar.

²SACCHARUM *Spicata.*

*Spiked Sugar Cane.*] Hath a thick-jointed fibrated root; upright jointed ſtems, ſix or eight feet high; oblong, waved leaves, two or three feet long; and the ſtalks terminated by ſpikes of purpliſh flowers.

Both theſe ſpecies are perennial in root; the ſtalks riſe ſeveral from each root; and in their growth reſemble the *arundo*, or common reed of the marſhes, but conſiderably larger, and inſtead of being hollow like thoſe plants, are filled with a whitiſh pith, containing the ſweet juice, or liquid, which renders theſe plants ſo very valuable; the ſtems are ſtrong, but brittle, generally growing to perfection in, from ſix or eight to twelve or fourteen months, becoming of a pale-yellowiſh colour; producing at top numerous ſmall flowers, collected into very large panicles, &c. ſometimes two or three feet long, each flower having only two ſmall valves for the corolla, and is wrapped up in long down; ſucceeded by oblong, narrow ſeeds included in the valves.

But it is the firſt ſort, *Saccharum Officinarum*, that is cultivated for ſugar, and for which purpoſe prodigious quantities are raiſed in the Weſt-Indies, and other hot countries; being propagated by ſuckers and cuttings, planting them in fields, in rows four or five feet aſunder, which ſoon ſhoot up into ſtalks, becoming fit to cut for uſe ſometimes in ſix or eight months, being then taken to a mill and ſqueezed between iron-caſed rollers, to expreſs the juice, which is then properly boiled and refined to form it into a due conſiſtence to become Sugar.

From the ſkimmings of the Sugar in the different boilings, and melaſſes, being the laſt drainings of the Sugar, mixing therewith a quantity of water, and the whole fermented, is extracted that ſpirituous liquor called rum, abounding with a ſalutiferous oilineſs, whence proceeds the excellence of that ſpirit, compared with brandy.

In this country however, this valuable plant cannot be cultivated without the aid of a hot-houſe all the year; ſo that only a few are raiſed by way of curioſity, being planted in pots of rich earth, and placed in the ſtove.

*Method of Propagation, &c.*

Their propagation is effected abundantly by ſlips or ſuckers from the root, and by cuttings of the main ſtalks.

In this country however, they are more generally propagated by ſlips from the bottom, or any ſide-ſhoots ariſing from the ſtems near the root, having earth raiſed about the bottom part, will ſoon emit fibres, and be fit for ſeparation; obſerving, theſe ſlips or off-ſets may be taken off at any ſeaſon, in which they appear fit for the purpoſe, being careful to detach them with ſome fibres to each, and plant them ſeparately in pots of rich earth, and plunged in the bark-bed, watered, and occaſionally ſhaded till they have got root; retaining them always in the bark-bed in the ſtove; and managed as other exotics of that repoſitory.

But in the Weſt-Indies, &c. theſe plants are moſt commonly propagated by cuttings of the tops of the old canes, or any part thereof, divided into lengths of from twelve to eighteen inches long, and placed horizontally in the ground three or four inches deep.

SALIX, Sallow, or Willow-tree.

The Sallow and Willow are principally of the tree kind of the deciduous tribe; valuable both as timber trees for various light uſes, and for all ſorts of baſket-work, poles, &c. Some ſorts alſo to diverſify garden plantations, there being many ſpecies growing from twenty to thirty or forty feet high, or more, garniſhed with oval, ſpear-ſhaped, and oblong leaves, in different trees, and dioecious apetalous flowers, diſpoſed in amentums.

Claſs and order, *Dioecia Diandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, diſpoſed in oblong, ſcaly, imbricated, katkins, or amentums, each ſcale containing one floret.—COROLLA, no petals, but cylindric nectarious glands in the centre.—STAMINA, in the males, generally two filaments, crowned with didymous quadrilocular antheræ.—PISTILLUM, in the females, an oval narrow germen, a ſcarcely diſtinguiſhable ſtyle, having two erect bifid ſtigmas.—PERICARPIUM, an oval-ſubulate, unilocular, bivalved capſule, having many ſmall ſeeds crowned with down.

There are about thirty different ſpecies of this genus, moſtly of the tree kind, of hardy growth, and ſome low under-ſhrubby, and herbaceous-like plants of no uſe; ſo that the tree kinds only merit conſideration for general culture, ſeveral of which grow to timber-trees; others are of great value to the baſket-makers, being planted in marſhy grounds, kept to low ſtools to produce a crop of ſhoots, or twigs to cut annually, for all kinds of wicker-work; and others being ſuffered to grow larger, to cut every three, or five, or ſix years for poles, uſeful for various purpoſes: and for garden culture, ſome particular ſorts may be introduced thinly in large plantations for variety; and ſome ſorts of the oſier kinds ſhould be planted in ſome moiſt place, to furniſh twigs for tying various garden articles.

The principal tree kinds in England are,

[1]SALIX *Caprea.*

*Common Sallow Tree.*] Grows to but a moderate height, having ſmooth, dark-green, brittle branches; oval, waved, rough leaves, indented at top, and woolly underneath.

*Varieties.*] Oblong, acute-pointed-leaved—ſilver-ſtriped leaved.

It grows abundantly in this country, but more frequently in dry than moiſt ſituations; is of a brittle nature, ſo is unfit for the baſket-makers; but will ſerve for poles, ſtakes, and to lop for fire-wood, and its timber is good for many purpoſes.

[2]SALIX *Alba.*

*White, or Silver-leaved Willow.*] Grows to a great height, and conſiderable bulk, having ſmooth pale green ſhoots; long, ſpear-ſhaped, acuminated, ſawed, ſilvery-white leaves, being downy on both ſides, with glands below the ſerratures.

This is the common White Willow, which grows abundantly about towns and villages, and by the ſides of rivers and brooks, &c.

[3]SALIX *Vitellina.*

*Yellow, or Golden Willow.*] Grows but to a moderate height, having yellow, very pliant, ſhoots; oval, acute, ſerrated, very ſmooth leaves, with the ſerratures cartilaginous, and with callous punctures on the foot-ſtalks.

[4]SALIX *Purpurea.*

*Purple, or Red Willow.*] Grows to a large height, having long, reddiſh, very pliable ſhoots, and long ſpear-ſhaped, ſerrated, ſmooth leaves, the lower ones being oppoſite.

[5]SALIX *Viminalis.*

*Viminalous or Oſier Willow.*] Grows but a moderate height, having ſlender, rod-like branches, very long, pliant, greeniſh ſhoots; and very long, narrow, ſpear-ſhaped, acute, almoſt entire leaves, hoary, and ſilky underneath.

[6]SALIX *Amygdalina.*

*Almond-leaved Willow.*] Grows to a middling height, with long, flexible, light-green branches and ſhoots; ſpear-ſhaped, ſerrated, ſmooth, ſhining-green leaves, on ſhort foot-ſtalks, having trapeza-ſhaped ſtipula.

[7]SALIX *Pentandria.*

*Pentandrous, Broad-leaved, Sweet-ſcented Willow.*] Grows to ſome conſiderable ſtature, having browniſh-green branches; oblong, broad, ſerrated, ſmooth, ſweet-ſcented leaves, ſhining above; and pentandrous flowers.

[8]SALIX *Triandria.*

*Triandrous Willow.*] Grows to a large ſtature, having numerous, erect, greyiſh-green branches, and pliant ſhoots; oblong, acute-pointed, ſerrated, ſmooth, ſhining-green leaves, eared at the baſe; and triandrous flowers.

[9]SALIX *Fragilis.*

*Fragile or Crack Willow.*] Riſes to a middling ſtature, with browniſh, very fragile, or brittle branches, long, oval-lanceolate, ſawed, ſmooth leaves of a ſhining-green on both ſides, having dentated-glandular foot-ſtalks.

This ſort in particular being exceedingly fragile, ſo that it eaſily cracks and breaks, is unfit for culture in oſier grounds.

[10]SALIX *Haſtata.*

*Haſtated-leaved Willow.*] Grows to a middling ſize, with long, green, pliable ſhoots; ſub-oval, acute, ſerrated, ſmooth, cloſe-ſitting leaves, having heart-ſhaped ſtipula.

[11]SALIX *Helix.*

*Helice of Theophraſtus, or Dwarf Yellow Willow.*] Grows but to a very moderate ſtature, having a yellow, rough-barked trunk, with browniſh branches; and narrow, lanceolate, ſerrated, ſmooth, blueiſh-green leaves, the upper ones obliquely oppoſite.

[12]SALIX *Babylonica.*

*Babylonian pendulous Salix, commonly called Weeping Willow.*] Grows to a largiſh ſize, having numerous, long, ſlender, pendulous branches, hanging down looſely all around in a curious manner, and long, narrow, ſpear-ſhaped, ſerrated, ſmooth leaves.

This curious Willow is a native of the Eaſt, and is retained in our hardy plantations for ornament, and exhibits a moſt agreeable variety; particularly when diſpoſed ſingly by the verges of any piece of water, or in ſpacious openings of graſs ground.

*Other eminent Sorts diſtinguiſhed by the following Names:*——Sound-growing Norfolk Willow.——Upland red Willow.——Broad-leaved Flanders Willow—Swallow-tail Willow—Dutch Oſier—Wire Oſier, &c. with ſome other varieties, particularly of the Oſier kinds, found principally in the oſier-grounds for the baſket-makers, diſtinguiſhed by different names, in different places.

The mode of flowering of all the ſorts of Willows is, in amentums, or katkins from the ſides of the branches, being male and female in different katkins on ſeparate trees; ripening in March and April.

All the above ſpecies and varieties of *Salix* are of the tree kind, very hardy, and remarkably faſt growers, and ſeveral of them attain a conſiderable ſtature, when permitted to run up to ſtandards, which frequently grow forty or fifty feet high, in twenty or thirty years, having proportionably large trunks; though ſome ſorts are apt to decay on the ſides, when large, and others will remain ſound to a conſiderable age and bulk: but all the ſorts may be eaſily raiſed from cuttings, both as ſtanards for timber; or kept down to dwarf ſtocks, for producing rods and twigs; or formed into pollards, or half-ſtandards for loppings.

Moſt of the ſorts grow naturally in England, &c. in great abundance, except the Triandrous and Haſtated Willows, which grow chiefly in Switzerland; and the Weeping Willow is a native of the Eaſt; but are all hardy enough to grow any where.

They are moſtly of the aquatic tribe, as being generally the moſt abundant, and of moſt proſperous growth in watery ſituations; they however will grow freely almoſt any where, in any common ſoil and expoſure; but grow conſiderably the faſteſt and ſtrongeſt in low moiſt land, particularly in marſhy ſituations, by the verges of rivers, brooks, and other waters; likewiſe along the ſides of watery ditches, &c. which places often lying waſte, may be employed to good advantage, in plantations of willows, for different purpoſes.——Some for ſtandards to grow to timber; ſome to form Oſier beds, and kept down to ſtools, a foot high, to furniſh an annual cutting of rods or twigs, for the baſket-makers; which, being cut every year, pay well for the the ground and trouble. Other plantations to furniſh poles, for cutting every three, four, five, or ſix years, for various uſes: and ſome planted alſo for pollards, forming ſtems, eight or nine feet high; which, branching out numerouſly at top, furniſh a lopping every four, five, or ſix years, both for poles, and for faggot-wood to burn. For all

of which purpoſes, they may be raiſed expeditiouſly by cuttings of all ſorts, either of the young ſhoots, one or two feet long, or large truncheons or poles, of from three to eight or ten feet in length, planted particularly in moiſt places; for the cuttings of theſe trees are remarkably free of growth, ſo that ſometimes, when uſed for common hedge-ſtakes, they ſtrike root freely and grow up to large trees.

For ornamental purpoſes in gardening, may introduce any of the ſorts in any hardy plantations for variety, as aforeſaid; but more particularly the white Willow, yellow Willow, purple Willow, pentandrous ſweet Willow, almond-leaved, and weeping Willow, being diſpoſed thinly in large out-plantations, will effect an agreeable diverſity: but the Babylonian, or weeping Willow, for its curious pendulous growth, demands culture in every garden; and which, for the general part, ſhould be diſpoſed ſingly or detached, both by the ſides of water, and in ſpacious opens of graſs ground; alſo near grottos, caſcades, caves, ruins, &c. in all of which, it will effect a moſt agreeable variety, with its numerous, ſlender, pendulous branches, bending arch-ways all around, terminated by very numerous, long, ſlender, hanging ſhoots. Likewiſe plantations of all the ſorts of Willow in aſſemblage with poplars, birch, and other aquatic trees, may be formed in any low watery ſituation, where other trees will not thrive, and they will exhibit an eligible diverſity, as well as ornament the premiſes.

Likewiſe for garden-culture, ſhould introduce ſome of the beſt Oſier kinds, which are of great uſe for tying and binding particular articles; ſuch as for tying the branches of eſpalier trees to the treillage; likewiſe in the nurſeries for binding bundles of trees for ſending to a diſtance; and in the market-gardens for binding their ware in bunches for market, ſuch as celery, turneps, coleworts, leeks, horſe-radiſh, &c. as practiſed by the London gardeners; alſo for tying up the leaves of early cabbages, &c. to facilitate their cabbaging and whitening in the heart: they are likewiſe uſeful for making and mending garden baſkets occaſionally: therefore it is proper, for all of thoſe purpoſes, to plant a quantity of cuttings, of the beſt Oſier kinds, in ſome moiſt ſituation, near water if poſſible, keeping them low, and they will furniſh a crop of twigs annually; a quantity of which being cut in winter, and tyed in bundles, may be preſerved for uſe all the year, which, when become dry, they being thrown into water will ſupple them for uſe.

*Method of Propagation and Culture.*

All the ſorts of Willows are propagated expeditiouſly by cuttings both of the young ſhoots of one or two years old, in lengths of half a yard or two feet long; and thoſe of ſeveral years growth in truncheons or poles, of from three or four, to eight or ten feet long, according to the purpoſes for which they are deſigned, as mentioned below; all of which will moſt readily ſtrike root, eſpecially in low moiſt ſoils: and the ſeaſon for planting them, is any time in open weather, from October until February: having generally a long iron-ſhod dibble, for planting the ſmaller cuttings, and an iron crow for making holes for the larger ſets, or make holes with a ſpade for very large long cuttings; though ſome uſe no inſtrument in planting the ſmaller cuttings, but ſharpen the ends of them, and thruſt them into the ground, eſpecially in ſoft land; but as this method is apt to force off the bark from the lower part of the cutting, it is therefore beſt to cut the bottom of each cutting even, and plant them with ſome inſtrument as above.

They are planted for different purpoſes; as for timber trees—to form oſier grounds—to cut for poles—pollards for lopping, &c. So the cuttings muſt be prepared and planted according as directed below, under their reſpective heads.

*For timber trees.*——The timber of Willows is eſteemed for ſeveral purpoſes, it being very white, of a fine grain, ſmooth, and takes a good poliſh, which renders it proper for many light articles: and, to raiſe them for timber, chuſe the larger growing ſorts, ſuch as the white, yellow, and purple, or red willows, &c. taking cuttings of the ſtrong young ſhoots, which may be planted at once where they are to remain, in any low marſhy ſituation, where they will grow amazingly faſt.

Having however prepared the ground, by proper digging, or plowing, as may be moſt convenient, and the ſituation admits; then provide a quantity of cuttings of ſtrong young ſhoots, of one or two years growth, cut to half a yard, or two feet lengths, which plant in rows, only ſix feet aſunder, and three or four diſtant in the rows, that they may draw each

each other up faſt in growth, and allow for a gradual thinning, inſerting each cutting two parts of three into the ground, by the method before obſerved; they will ſoon emit roots, and ſhoot ſtrongly at top in ſpring and ſummer, obſerving to clear all away but one of the ſtrongeſt leading ſhoots for a ſtem, which ſuffer to run up always at full length in its future growth; remarking, that in a few years, when the trees approach one another, they ſhould be thinned, which thinnings will ſerve for poles for ſeveral uſes, repeating the work of thinning in a few years more, according as the branches of the different trees interfere, leaving them at laſt about twelve or fifteen feet aſunder, to attain full growth: thus they will draw each other up very expeditiouſly with ſtreight handſome ſtems, forty or fifty feet high or more; and in twenty or thirty years, will be fit to fell for timber.

*For Oſier Grounds.*——Oſier grounds are plantations of oſier Willows, in low ſtools for producing twigs annually for the baſket makers, being formed in any low watery ſituation, planted with cuttings of the beſt oſiers, and all the other moſt pliant ſort of Willows, in rows two or three feet aſunder, and always kept to low ſtools a foot high, in order to force out a more plentiful annual crop of twigs and rods, from three or four, to ſix or eight feet long, of a pliant tough nature, fit for working into all kinds of baſket and wicker-work, which being cut annually in winter for ſale, are worth from five or ſix, to eight or ten pounds an acre per annum: ſo that, oſier plantations being thus formed in any low watery waſte land, incapable of yielding other produce to perfection, will turn out to great advantage; and, if near any navagable river, for the convenience of water carriage, it will ſtill be more advantageous: on which conſideration, very large tracts of waſte, boggy grounds and iſlands, along the river of Thames, is employed in oſier grounds, for the London conſumption.

Therefore, making choice of any convenient, low, moiſt ſituation, let it be digged or ploughed, for the reception of the oſiers: then, in the proper ſeaſon before-mentioned, gather a ſufficient quantity of oſier ſets of different ſorts, which muſt be cuttings of the one or two years old ſhoots, cut into two feet and half lengths; theſe being provided, then draw lines for planting them, two feet and half diſtance, inſerting each cutting about a foot and half into the ground, leaving the reſt out to form the ſtool, and let them be two feet and half diſtance in each row: having thus formed the plantation, the cuttings will root firmly in the ſpring, and ſhoot at top tolerably ſtrong in ſummer, each ſtool generally throwing out ſeveral ſhoots, of an erect growth; obſerving, during this firſt ſummer, to keep down all large weeds, that the ſtools may have full ſcope to produce the firſt ſhoots as ſtrong as poſſible, which, by the end of autumn, will probably be advanced ſome conſiderable length; and if much wanted, may be cut in the following winter; though, for a full plantation, they ſhould generally be ſuffered to continue their growth for two or three years, till the ſtools are firmly rooted and become ſtrong; then cut down all the tops cloſe to the head of the ſtools; they will ſerve for poles, &c. next year the ſtools will ſhoot out ſtrong, a numerous crop of twigs and rods, fit for cutting for the baſket-makers in winter following; and, the ſtools ſtill remaining, furniſh an annual crop, fit for cutting every winter, which ſhould be cut always down to the head of the ſtool, as juſt above obſerved; ſorting the twigs in ſizes, tie them in bundles, and ſtack them up for uſe.

*To cut for Poles.*——Willow poles are uſeful for various huſbandry purpoſes; ſuch as for handles for implements, and for making hurdles, &c. and plantations of ſtools may be made in any waſte, watery places, as before obſerved, to cut every three, or four, or five, or ſix years, according to the purpoſes for which they may be required.

For this purpoſe, procure a quantity of ſets, of two year old ſhoots, in cuttings about two feet and half long; plant them in rows, a yard aſunder, introducing each cutting two parts of three into the ground; they will all readily grow, and each ſend out ſeveral erect ſhoots, which, in three or four years, will become large poles fit to cut for uſe.

Or large cuttings or truncheons, three or four feet long, thruſt down along the ſides of rivers, brooks, ditches, &c. they will take root, and ſhoot out ſtrongly at top for poles, as above.

*To form pollard Standards.*——Willow pollards are common almoſt every where, they being raiſed commonly from large ſets or cuttings of poles, three yards long, or more, planted along the ſides of rivulets or watery ditches, &c. and that being generally topped

or

or diveſted of the leading ſhoot, they do not run up with tall ſtems, but branch out all around, at ſeven or eight feet height, into many erect branches, which, in four, five, or ſix years, being lopped down to the head of the ſtem, ſerve for poles, for hurdles, &c. alſo for fuel, as before obſerved; and the pollards ſhooting out again, they in this manner furniſh a lopping every fifth, ſixth, or ſeventh year, and thereby prove very profitable for many purpoſes.

The ſets or cuttings for raiſing theſe pollards, may be obtained in plenty from the loppings of any old pollard Willows, &c. chuſing the large ſtraight poles, cut into nine or ten feet lengths, which muſt be planted either with an iron crow, or ſome ſimilar implement, driven into the ground, to make wide holes, two feet and half deep, for their reception; or, if the ground is impliant and ſtubborn, may dig holes with a ſpade that depth, planting one ſet in each hole, placing them two feet and half in the ground, leaving ſix or ſeven above for a ſtem: thus, theſe ſets, though ſo large and long, if planted in moiſt places, will readily ſtrike root, and ſhoot out at top the following ſpring and ſummer, into many erect branches, which, after four or five years growth, become fit to top for poles, &c. and the trees will thus continue to afford a lopping every fifth, ſixth, or ſeventh year; or may grow larger, according to the purpoſes for which the loppings may be wanted.

*To form Hedges.* —— Sometimes Willow hedges are raiſed in ſome outward place, along ditch ſides, or elſewhere, when deſigned to form either a fence, blind, or ſhelter expeditiouſly; which is eaſily effected by cuttings, either of ſtrong young ſhoots, cut into two or three feet lengths, and planted in a row half a foot aſunder, and fifteen or eighteen inches deep; or with larger truncheons of ſeveral years growth, cut into ſets, two, three, four, or five feet long or more; and in either caſe, that when the ſets have made the firſt years ſhoot, the ſhoots may be plaſhed together in winter, both to ſtiffen the hedge and give it a thicker form: afterwards it may be kept regular by clipping it annually, or may be ſuffered to take its own natural growth, as occaſion ſhall require.

Obſerve however, that to form a Willow hedge, as ſoon as poſſible, you may uſe large ſtreight ſets, of five or ſix feet long, and plant them chequer-ways, placing each ſet half a yard or two feet in the ground, leaving three or four feet above; which, being arranged croſs one another in the above mentioned chequer manner, and ranged all an equal height, they will at once form a good firm fence, immediately fencible againſt cattle.

Or, where a ſpeedy fence is wanted, by way of blind or ſhelter, may procure a quantity of loppings, five, ſix, or ſeven feet long, well furniſhed with branches to the bottom, which plant in a deepiſh trench, pretty cloſe together, they will grow and form a ſort of fence directly.

*To furniſh Twigs for Garden Uſe*—Oſier twigs being uſeful in many gardens for various tyings, as we before obſerved, it is eligible to cultivate a few of the beſt oſiers in moſt gardens, to ſurniſh a ſupply for the different purpoſes; chuſing ſome moiſt ſituation, or near any watery ditch, or other water in any bye place, or where moſt convenient: and, having procured a quantity of the moſt pliant kind of Oſier ſets, cuttings of young ſhoots, half a yard or two feet long, which plant in the place allotted in rows, planting or thruſting them two parts of three into the ground; they will grow freely, and furniſh plenty of twigs every year, managing them as obſerved for thoſe of the *Oſier Ground.*

As to the culture of all the above different plantations of Willows, they require but little; which is principally the keeping down large weeds the firſt and ſecond year after planting, which is more particularly requiſite in the plantations of young low cuttings, till they are a little advanced in growth.

*For Nurſery Collections.*—Collections of the different ſorts of Willows, ſhould alſo be kept in all nurſery grounds, both public nurſeries for ſale, and in private nurſeries, to ſupply plantations occaſionally, raiſing them generally from young cuttings, of a year or two old, in half yard or two feet lengths, and planted in rows, two or three feet aſunder, to grow till wanted.

## SALLAD HERBS.

Various ſorts of eſculent herbs of different genera, are uſed for ſallading, which by different ſowings, plantings, &c. are obtained at all times of the year; but the moſt generally eſteemed ſorts, may be compriſed under the following three heads. — *Principal Sallad Herbs.—Small Sallad Herbs.—Occaſional Sallad Herbs.*

*Principal*

*Principal Sallad Herbs.*—Theſe conſiſt chiefly of three ſorts, *viz.* lettuce, all the varieties —endive, all the different ſorts—and celery, all the varieties—which three principal ſorts are all raiſed from ſeed, by different ſowings and tranſplantings; and are in beſt perfection for uſe when arrived to full growth: either of which may be eaten as a Sallad alone, or all of theſe ſorts mixed together, or any, or all of them mixed with a proper quantity of ſmall ſallading, or other Sallad Herbs occaſionally: but with ſmall ſallading in particular is very eligible in winter and ſpring; as the ſmall ſallading, being of a warm nature, renders the Sallad more grateful and wholeſome. Lettuce is generally eſteemed as the moſt material Sallad Herb, for general uſe, at moſt times of the year, but particularly in ſummer, when full grown and firmly cabbaged; but by ſeveral ſowings and tranſplantations at different times, from January and February, until September or October, in different ſituations, according to the ſeaſon, the plants may be obtained in tolerable plenty almoſt the year round, but always more finely cabbaged in ſummer that in winter. And as to the endive and celery, they are excellent for autumn and winter Sallads, they being in full perfection in September, October, and November, when they will be full grown and finely blanched, and they often continue in tolerable perfection all winter and ſpring.—But for other particulars, together with the method of culture of theſe three principal Sallad Herbs. See their reſpective genera, LACTUCA, CICHORIUM, and APIUM.

*Small Sallad Herbs.*—The principal ſorts, denominated Small Sallad Herbs, are creſſes, muſtard, radiſh, rape, and turnip, alſo lap-cabbage-lettuce: all of which herbs, conſidered as ſmall ſallading, are always in perfection as ſuch when quite young, or only a few days old, whilſt in the ſeed leaf, cutting them up, ſhank and top together, cloſe to the ground, as when they are thus quite young they eat exceeding tender, with an agreeably warm reliſh, for they being moſtly of ſo warm a nature, that if ſuffered to grow old for ſallading, they would eat very hot and diſagreeably ſtrong-taſted, but being uſed when quite young, as above, whilſt they remain of a palatably warm reliſh, they are highly proper to mix in all winter and ſpring Sallads in particular; though many people are fond of them at moſt times of the year; and many often uſe them alone, particularly in winter and ſpring; they, however, are preferable when mixed with lettuce and the other large ſallading.

All theſe Small Sallad Herbs are raiſed from ſeed, which, for the purpoſe of ſallading are ſowed at all times of the year, when they are required, in the open ground in the ſpring and ſummer, and in winter under frames and glaſſes, and occaſionally in hot-beds; and where a conſtant ſupply is wanted, a repetition of ſowings is requiſite every week, ten days, or a fortnight, being ſowed generally in ſhallow flat drills, very thick, and only juſt covered with earth. But for the particular culture of theſe herbs for ſallading, ſee the article SMALL *Sallad Herbs.*

*Occaſional Sallad Herbs.*—This head comprehends ſeveral other excellent Sallad Herbs; but not being in ſuch general eſtimation as the former ſorts, are only uſed occaſionally, *viz.* Corn Sallad or lamb's lettuce — purſlane—ſpear-mint—water-creſs—borrage and borrage-flowers — naſturtium-flowers — chervil —burnet; and ſometimes red-cabbage—radiſhes — red beet-root—finochia or Azorian fennel — horſe-radiſh — young onions, &c. each of which requiring a particular culture, we refer to their reſpective genera, where their uſes as Sallad Herbs, &c. and mode of propagation, &c. is fully exhibited.

SALSOLA, Glaſs-wort, and Stone-crop-tree.

This genus is compoſed of herbaceous annuals and perennials of but little merit as garden plants, and one ſhrubby ever-green, proper for the ſhrubbery.

Claſs and order, *Pentandria Digynia.*

*Character.*] CALIX, five oval permanent leaves.—COROLLA, no petals.—STAMINA, five very ſhort filaments inſerted into the diviſions of the calix—PISTILLUM, a round germen, a double, or a tripartite ſtyle, and recurved ſtigmas.—PERICARPIUM, an oval unilocular capſule lodged in the calix, having one large ſeed.

There are many herbaceous ſpecies, and and ſome of ſhrubby growth; one of the latter being the only ſort generally cultivated in the Engliſh gardens, *viz.*

SALSOLA *fruticoſa.*

*Shrubby Glaſs-wort, commonly called Stone-crop tree.*] Riſes with a ſhrubby erect ſtem, branching numerous and erectly, four or five feet high, cloſely garniſhed with very ſmall obtuſe fleſhy leaves, like the common Stone-crop on the walls.

This

This ſpecies was formerly retained in the genus *Chenopodium*, but is lately made a ſpecies of *Salſola*.

It inhabits the ſea-ſhores in England, France, and Spain, &c. but is retained in many curious gardens, in the ever-green collection, to adorn the ſhrubbery compartments, allowing it generally a ſheltered ſituation.

The propagation of this ever-green, is by ſuckers, layers, and cuttings; many ſtems generally riſing from the root, which may be divided in autumn or winter, into ſo many ſeparate plants; and layers or cuttings of the young branches in autumn or ſpring will be well rooted by autumn following.

SALVIA, Sage, Clary, &c.

It comprehends under-ſhrubby, herbaceous, and ſhrubby plants, both for the kitchen garden, pleaſure ground, and green-houſe, garniſhed moſtly with ſpear-ſhaped, oval, and oblong leaves, and ſmall, monopetalous, ringent flowers, generally terminating the branches in ſpikes.

Claſs and order, *Diandria Monogynia*.

*Characters.*] CALIX, is monophyllous, wide at the mouth and bilabiated—COROLLA, is monopetalous, tubulous below and ringent above, having the upper lip concave and indented, and the under one broad and trifid. —STAMINA, two ſhort filaments, ſplit into two parts, one of which ſupports the antheræ —PISTILLUM, a quadrifid germen, a long ſlender ſtyle, and bifid ſtigma.—PERICARPIUM, none; four roundiſh ſeeds lodged in the calix.

To this genus *Salvia*, is now joined *Sclarea*, or common Garden Clary, and *Horminum*, or Wild Clary, &c. amounting in the whole to above thirty ſpecies, though not half ſo many that merit culture, as garden plants, conſiſting of hardy under-ſhrubby, and herbaceous perennials for the open ground, and ſhrubby ever-greens for the green-houſe.

*Hardy under-ſhrubby kinds.*

Under this head is comprehended, the common Sage of the kitchen-garden, having many varieties; all under-ſhrubby perennials, exotics from the ſouthern parts of Europe, but are all hardy enough to ſucceed here in the open air, the year round.

[1]SALVIA *Officinalis.*

*Common officinal Sage.*] Riſes with ſhort, under-ſhrubby, hairy ſtems, branching numerouſly from the bottom, two feet high, or more, forming a very buſhy head; ſpear-ſhaped-oval, entire, ſlightly crenated, rough leaves, and the branches terminated by ſpikes of blueiſh flowers, having acute cups.

*Varieties.*] Common broad-leaved green Sage.——Common culinary red Sage, being of a black-red colour.——Broad-leaved, hoary, balſamic Sage, having generally the broadeſt leaves of all the ſorts, ſtanding on long foot-ſtalks.——Wormwood Sage.——Narrow-leaved hoary Sage, commonly called Sage of Virtue, having the baſe of the leaves ſometimes auriculated or indented in form of ears, and ſometimes not eared.——Lavender leaved Sage.——Variegated green Sage.—Variegated red Sage.

They all flower in June and July, and are ſometimes ſucceeded by ripe ſeed in autumn.

This ſpecies and varieties are all very hardy plants, perennial in root, ſtem, and branches, and retain their leaves the year round. They are plants of ſovereign virtue, as the name imports, and the leaves are the only uſeful part, being proper for various culinary purpoſes, and for medical uſes; are alſo often uſed in the manner of tea, by way of medicine, and eaten with bread and butter, and uſed for making ſage-cheeſe, &c. theſe plants therefore, demand culture in every family-garden; and any, or all the ſorts may be cultivated for uſe, they poſſeſſing nearly all the ſame quality; but the red Sage is the moſt commonly cultivated for general kitchen purpoſes; and the broad-leaved hoary Sage, and the Sage of Virtue, is often preferred for tea and other medical uſes, though it is probable any of the ſorts may be equally eligible, as being all varieties of one ſpecies.

*Hardy herbaceous kinds.*

There are many herbaceous ſpecies of *Salvia*, ſome of which formerly compoſed different genera, ſuch as *Sclarea*, or Garden Clary, and *Horminum*, or Wild Clary, &c. are moſtly of foreign growth, but grow freely in our gardens, in the open ground; though they poſſeſs no great merit, except one for culinary and medical uſe; and the others principally as plants of variety, and conſiſt of biennials, perennials, and annuals, garniſhed moſtly with broad rough leaves.

The moſt noted ſpecies are,

[2]SALVIA *Sclarea.* (*Biennial.*)

*Sclarea or common Garden Clary.*] Hath a fibrated biennial root, crowned with broad, oblong, heart-formed, ſerrated, rough, hairy leaves;

leaves; upright, thick ſtems, two feet high, branching oppoſitely, having all the branches terminated by large looſe ſpikes of pale blue flowers, attended by concave acuminated bractea, longer than the corolla and calix.

*Varieties.*] Broad-leaved—Long-leaved—Moſt wrinkled-leaved.

This ſpecies and varieties, are biennials, have all large, thick, woolly leaves, that impart a ſtrong odour, and are the uſeful part of the plants, which are cultivated in kitchen-gardens, for culinary uſes; being raiſed from ſeed annually, and planted out a foot and half aſunder, where they ſpread out into large leaves for uſe, till next ſummer; when they ſhoot up into ſtalk for flower and ſeed; then totally periſh.

[3]SALVIA, *Verbenaca.* (*Perennial.*)

*Verbenaceous common Wild Clary, or Oculus Chriſti.*] Hath a fibrated perennial root, oblong, ſinuated, ſerrated, wrinkled leaves; and declinated ſtems, a foot long, terminated by whorled ſpikes of ſmall blue flowers, having the corolla narrower than the calix.

It grows wild in England, &c. its virtues are ſuppoſed nearly the ſame as the garden-clary; and the ſeed being of a viſcous nature, is ſometimes uſed for clearing the eye from any moat that happens to fall into it, putting one of the ſeeds into one corner, and moving it about, the duſt ſticking thereto, removes it out of the eye.

[4]SALVIA *Indica.* (*Perennial.*)

*Indian Clary with a variegated Flower.*] Hath a fibrated perennial root, upright four-cornered ſtems, three or four feet high, heart-ſhaped, acutely crenated leaves, the upper ones ſeſſile, and half the upper part of the ſtalks adorned with blue variegated flowers, in remote whorls.

[5]SALVIA *Glutinoſa.* (*Perennial.*)

*Glutinous yellow Clary.*] Hath a ſtrong, fibrated, perennial root; heart-ſhaped, ſaggitated, acutely ſerrated, glutinous leaves, upright four-cornered, glutinous ſtems, three or four feet high, terminated by ſpikes of yellow flowers, in cloſe whorls.

[6]SCLAREA *Horminum.* (*Annual.*)

*Horminum, or purple-topped annual Clary.*] Riſes with upright ſtalks, a foot and half high, obtuſe crenated leaves, and the ſtalks terminated by whorled ſpikes of ſmall purpliſh flowers, with coloured bracteal leaves at top.

*Varieties.*] With purple tops—with red tops.

All theſe herbaceous ſpecies flower moſtly in June, and the ſeeds ripen in autumn.

They are all hardy enough to grow in any common ſoil, the firſt of which being for the kitchen-garden, and the others to encreaſe the variety of the herbaceous collection.

*Tender ſhrubby kinds for the Green-houſe.*

Conſiſts of four or five ſhrubby ever-green plants of the Sage kinds, natives of different warm countries, and retained here in our green-houſe collections for variety.

[7]SALVIA *Mexicana.*

*Shrubby Mexican Sage.*] Riſes with a ſhrubby branchy ſtem, eight or ten feet high; having four-cornered, purpliſh branches; oval leaves, pointed at both ends, and ſerrated; and cloſe ſpikes of blue flowers at the ends of the branches.

[8]SALVIA *Africana.*

*Shrubby African Sage.*] Riſes with a ſhrubby branching ſtem, four or five feet high; roundiſh ſerrated grey leaves, truncated and indented at the baſe; and whorled ſpikes of blue flowers towards the ends of the branches.

[9]SALVIA *Aurea.*

*Golden African Sage.*] Riſes with a ſhrubby branching ſtem, ſix or ſeven feet high; roundiſh entire leaves, truncated and indented at the baſe; and ſhort ſpikes of golden coloured flowers at the ends of the branches.

[10]SALLVIA *Pomifera.*

*Pomiferous or Apple-bearing Sage of Crete.*] Riſes with a ſhrubby branchy ſtem, four or five feet high, ſpear-ſhaped, oval, entire, ſlightly crenated, hoary leaves, and ſpikes of blue flowers, having obtuſe cups.

The branches of this ſort have ſometimes glandular protuberances as big as apples; hence the name Pomiferous Sage.

[11]SALVIA *Canarienſis.*

*Canary Sage.*] Riſes with a ſhrubby branching downy ſtem, garniſhed with haſtated-triangular, obtuſe, crenated leaves; and whorled ſpikes of blue flowers at the ends of the branches.

All the above ſpecies of *Salvia*, both hardy and tender kinds, are principally of the verticillate tribe, or ſuch as produce their flowers in a verticillus, or whorls round the ſtalks, ſome having the whorls ſtanding almoſt cloſe, others placed remote (ſee VERTICILLATUS and VERTICILLUS); and the flowers are univerſally monopetalous and rin-

gent, and generally ſmall, but numerous in each ſpike. See the *Characters*, &c.

All the under-ſhrubby and ſhrubby kinds, both hardy and tender ſorts, are durable in root, ſtem, and branches, and remain in leaf the year round.

But the herbaceous kinds are furniſhed with ſtems only in ſummer.

The *Salvia Officinalis*, or common Sage and varieties, conſidered as culinary and medical plants, merit culture in every kitchen-garden, allowing them a moderately dry ſoil, and ſunny ſituation, to enable them to ſtand the winter more effectually; for if planted in moiſt or ſhady places, they are liable to ſuffer by ſevere froſts: they are eaſily raiſed from ſlips, as hereafter directed, and afterwards planted in rows a foot and half aſunder; in which they will grow large buſhy plants, and remain ſeveral years, furniſhing leaves plentifully the year round; which are proper for uſe, both freſh gathered from the plants, and when dried; though for culinary purpoſes, they are beſt when freſh gathered, taking the young ſide-ſhoots or tops, ſlipping or cutting them off: and towards the latter end of ſummer, about July or Auguſt, gather a quantity to dry for tea: being careful in all the gatherings not to ſtump them too cloſe, particularly in autumn and winter.

But the varieties of the common Sage, may alſo be employed to diverſify the fronts of ſmall ſhrubbery clumps, &c. particularly the variegated kinds.

As to the merit of the herbaceous kinds, the *Garden Clary* being a culinary and medical herb, muſt be ſtationed in the kitchen-garden; and all the others, being conſidered principally as plants of variety, as aforeſaid, may be employed to diverſify any of the compartments of the pleaſure ground; all of which herbaceous kinds are eaſily raiſed from ſeed; and the ſeedlings, when two or three inches high, ſhould be planted out. See their *Propagation*, &c.

And as to the tender ſhrubby kinds, they requiring ſhelter from froſt, muſt be kept always in pots, in order for moving to a green-houſe in winter; and as being elegant evergreens, they will effect an agreeable variety among the exotics of that conſervatory.

*Propagation and general Culture of the common Sage kinds.*

The propagation of all the varieties of common Sage, is effected plenteouſly by ſlips or cuttings of the young ſhoots from the ſides of branches; and may alſo be raiſed from ſeed.

By ſlips or cuttings.——The ſlips both of the former and ſame years growth, planted in April or May, will readily grow. Slips of the former years ſhoot may be obtained plentifully any time in ſpring, but ſhould not be planted earlier than April; which however, if planted any time in April, or early in May, they will root freely, and form good plants againſt winter: but young ſlips, ſhoots of the year, are rarely fit for ſlipping before the middle of May, or beginning of June: theſe however moſt readily ſtrike root in a ſhort time, and aſſume a free growth: in either caſe, taking opportunity of moiſt weather, and having recourſe to ſome good buſhy plants; ſlip off a quantity of the moſt robuſt ſide-ſhoots, about five, ſix, or ſeven inches long; trim off all the lower leaves, then in ſome ſhady border proceed to plant them with a dibble in rows, half a foot aſunder, planting them down almoſt to their tops; giving water directly, to ſettle the earth cloſe, as well as to promote an early emiſſion of fibres, repeating the waterings occaſionally in dry weather; and the ſlips will ſoon emit fibres, and ſhoot freely at top: obſerving, if they ſhould ſpindle up with ſlender ſhoots, or run up to flower, it is proper to top them, in order to force out laterals, to aſſume a buſhy growth: thus they will form tolerable buſhy plants by Auguſt or September; when, or in ſpring following, they may be removed, with balls of earth about their roots, and planted where they are finally to remain, either in four feet beds, or in continued rows, a foot and half aſunder, if deſigned as a cloſe plantation for uſe: and thoſe deſigned for the pleaſure ground ſhould be diſpoſed accordingly.

Sometimes Sage, as before obſerved, having grown into large buſhy plants, with numerous branches riſing near the ground, which touching the earth, have formed plenty of fibres at bottom; and that being ſlipped off ſeparately with the fibres thereto, each immediately commences a proper rooted plant; they may either be ſlipped off as the plants ſtand in the ground, or the bunches of plants may be taken up and divided into as many ſeparate ſlips as are furniſhed with roots: and as they thus directly form rooted plants, they may be planted at once where they are to remain.

However, thoſe raiſed from young ſlips, generally form the ſtrongeſt buſhy plants in the end.

By

By Seed.——The raiſing theſe plants from ſeed, is hardly worth practiſing, ſince they may be propagated ſo eaſily by ſlips or cuttings. However, the ſeaſon for ſowing the ſeed, is any time in April, in a bed of light rich earth; ſow it evenly, and rake it in; the plants will ſoon come up: and when about two or three inches high, prick out the ſtrongeſt in nurſery-rows, half a foot aſunder, to gain ſtrength till September or ſpring following; then tranſplant with balls, where they are always to ſtand.

As to the culture of this ſpecies of Sage and varieties, all that is required is, the keeping them clean from weeds in ſummer, cutting down the decayed flower-ſtalks in autumn, and ſlightly digging between the rows in winter; and, if the ground ſhould be impoveriſhed, add a portion of rotten dung occaſionally in autumn, and dig it in.

*Propagation, &c. of the herbaceous kinds.*

All the herbaceous kinds of *Salvia* are eaſily raiſed from ſeed: ſowed in ſpring in the open ground; and the perennial ſorts alſo, by parting the roots.

By Seed.—The Garden Clary, being a biennial, muſt be raiſed every year from ſeed. Sow it in March, in any bed or border of common earth, and rake it in; and when the plants have got leaves two or three inches long, plant them out in ſhowery weather, in rows eighteen inches diſtance, and the ſame diſtance in the rows; they will ſoon get root, and grow large, and furniſh large leaves, fit for uſe in autumn, winter, and the following ſpring.

The perennial ſorts are alſo raiſed from ſeed, ſowed in a bed of light earth in March, and raked in, and the ſeedlings planted out in ſummer, in nurſery-rows till autumn, then tranſplanted into the borders, &c.

And the annual ſorts may be ſowed in ſpring, about the borders, in patches to remain.

By Parting the Roots—The perennial kinds only can be increaſed by this method, which may be performed in autumn, or early in the ſpring.

*Propagation, &c. of the tender ſhrubby kinds.*

All the five tender ſhrubby kinds for the green-houſe, are eaſily propagated by cuttings of the young ſhoots in ſpring and ſummer. If in ſpring, a quantity of cuttings planted in pots, and plunged in a hot-bed, will very ſoon emit roots at bottom, and ſhoots at top, when they ſhould be gradually hardened to the full air. But cuttings planted in ſummer, will often ſtrike without the aid of a hot-bed, planted either in pots, or in a bed of natural earth, under frames and lights, or covered cloſe with hand-glaſſes, ſhaded from the mid-day ſun, and occaſionally watered.

The plants muſt afterwards be potted off ſeparately, and managed as other ſhrubby exotics of the green-houſe. See GREEN-HOUSE PLANTS.

SAMBUCUS, Elder-tree.

This genus conſiſts of hardy deciduous trees and ſhrubs, and herbaceous perennials, proper for ſome uſeful purpoſes in gardening and for diverſifying hardy plantations; alſo for domeſtic and medical uſes in their leaves, flowers, and fruit; are all garniſhed with large winged leaves and numerous ſmall rotaceous flowers, moſtly in cymoſe umbels towards the ends of the branches, ſucceeded by large bunches of black and other coloured berries in autumn.

Claſs and order, *Pentrandria Trigynia.*

*Characters.*] CALIX, is ſmall, monophyllous, five parted, and permanent.—COROLLA, is monopetalous, rotated, and concave, and cut into five obtuſe reflexed ſegments.—STAMINA, five awl-ſhaped filaments, having roundiſh antheræ.—PISTILLUM, an oval germen under the corolla; no ſtile, but inſtead thereof, a ſwelling glandule and three obtuſe ſtigmas—PERICARPIUM, a roundiſh unilocular berry including three angular ſeeds.

There are only four ſpecies in this genus, three of which are of the tree and ſhrub kind, and one is an herbaceous perennial: two of them are common in England, &c. namely, the Common Black Elder-tree, and the Herbaceous Dwarf Elder; the other two are foreigners, one being from the ſouth of Europe, and the other of America; but are all hardy enough to grow here in any ſituation.

*Tree and ſhrub kinds.*

'SAMBUCUS *Nigra.*

*Common Black Elder-tree.*] Riſes with a tree-ſtem, branching numerouſly into a large ſpreading head, twenty or thirty feet high; pinnated leaves, of two or three pair of oval lobes and an odd one; and large, cymoſe, five-parted umbels of white flowers towards the ends of the branches, ſucceeded by large

bunches of black, and other different coloured berries, in the varieties.

*Varieties.*] Common Black-berried Elder-tree.—White-berried Elder.—Green-berried Elder.—Laciniated or Parſley-leaved Elder, having the folioles much laciniated, ſo as to reſemble parſley-leaves.—Gold-ſtriped-leaved Elder.—Silver-ſtriped Elder.—Silver-duſted Elder.

All theſe being varieties of *Sambucus Nigra*, have, for the general part, five or ſeven-lobed leaves; are of a tree-like growth, and quinquepartite umbels of flowers and fruit; the common Black-berried Elder, however, is the moſt generally known variety, and the moſt commonly cultivated; ſometimes as ſtandards among foreſt trees, but more frequently in forming outward hedges expeditiouſly, as being a very faſt grower; likewiſe often in detached ſtandards for the ſake of their berries for making of Elder-wine; and all the varieties may alſo be employed for diverſifying plantations: all the varieties make very ſtrong ſhoots, full of a white pithy ſubſtance, but becomes woody as they advance in age, and the old wood becomes ſolid and very hard, fit for many purpoſes: all of which varieties will grow in any ſituation, and may be raiſed very expeditiouſly by cuttings of the year-old ſhoots. See the *Propagation*.

The bark, buds, leaves, and flowers are uſed in medicine, being ſovereign in many diſorders.

And the ripe berries make an excellent cordial wine.

[2]SAMBUCUS *Racemoſa.*

*Racemoſe Red-berried Elder.*] Riſes with a tree-like ſtem, branching ten or twelve feet high, having reddiſh-brown branches and buds; pinnated leaves of ſix or ſeven oval deeply-ſawed lobes, and compound, oval, racemous cluſters of whitiſh-green flowers, ſucceeded by oval cluſters of red berries.

This is a reſident of the mountainous parts of the ſouth of Europe, and is retained in our gardens as a flowering ſhrub, having a peculiar ſingularity in its oval-cluſtered flowers and berries.

[3]SAMBUCUS *Canadenſis.*

*Canada Shrubby Elder.*] Riſes with a ſhrubby ſtem, branching eight or ten feet high, having reddiſh ſhoots; ſomewhat bi-pinnated leaves, often ternate below, the others compoſed of five, ſeven, or nine oval lobes; and towards the ends of the branches, cymoſe, quinquepartite umbels of flowers, ſucceeded by blackiſh red berries.

*Herbaceous kind.*

[4]SAMBUCUS *Ebulus.*

*Ebulus, or Herbaceous Elder; commonly called Dwarf Elder.*] Hath a thick, creeping, tough, perennial root, ſpreading widely around; herbaceous, ſtrong, pithy, green ſtems three or four feet high; large pinnated leaves, of from three or four to ſix or ſeven pair of long, acute-pointed, indented lobes, with leafy ſtipula, and large, cymoſe, three-parted umbels of white flowers, ſucceeded by black berries in autumn.

This is a perennial, and grows wild in England in hedges, banks, and fields, but is admitted in ſome gardens for variety and medical uſes.

*Variety.*] Laciniated-leaved, having the folioles beautifully jagged into ſegments.

All the ſorts of Elder are of the deciduous tribe, very hardy, and grow freely any where; are generally free ſhooters, but particularly the *Common Elder* and varieties, which make remarkably ſtrong, jointed ſhoots, of ſeveral feet length, in one ſeaſon; and they flower moſtly in ſummer, except the *Racemoſe Elder*, which generally begins flowering in April; their modes of flowering being in cymoſe umbels, and racemoſe cluſters, as in their reſpective deſcriptions; riſing generally towards the termination of the preceding year's ſhoot, each bunch conſiſting of numerous ſmall, wheel ſhaped, concave, ſemi-quinquefid flowers; and the bunches being large, ſpreading, and very abundant, are exceedingly conſpicuous; but they emit a moſt diſagreeable odour; are ſucceeded in moſt of the ſorts, by large bunches of ripe berries in autumn, which, although very unpalatable to eat, are in high eſtimation for making that well known cordial liquor called Elder wine, particularly the common Black-berried Elder.

The merit of Elders in gardening may be both for uſe and ornament, eſpecially in large grounds.

With reſpect to the tree and ſhrub kinds, the Common Elder may be introduced occaſionally in foreſt-tree plantations, and as detached ſtandards, in any bye-place, for the ſake of their berries, as before hinted; and all the ſorts may be employed to diverſify large ornamental plantations, diſpoſed, however,

ever, but thinly, particularly the Common Elders, as their flowers ſend forth a ſtrong diſagreeable ſcent, ſo ſhould be but ſparingly introduced near much frequented places; however, the different varieties thereof may be diſperſed in out-plantations ſo as to effect an agreeable diverſity; but as to the *Sambucus Racemoſa* and Canada Elder, they may be diſpoſed in any of the ſhrubbery compartments, more particularly the former, which will exhibit a conſpicuous ſingularity in its mode of flowering and fruiting.

And the Common Elder, being a very faſt grower, is often employed in forming outward hedges along ditch-ſides, or the ſides or tops of banks, where it is neceſſary to form a hedge-fence as cheap and expeditiouſly as poſſible, which may be raiſed from cuttings of the ſtrong ſhoots of from one or two to five or ſix feet long, planted at once where the hedge is intended, a foot diſtance in the row, and from one to two feet deep in proportion to their length; but the ſhort and middling cuttings generally form the cloſeſt hedge from the bottom: though long cuttings are ſometimes uſed in order to form an immediate fence, which being arranged chequer-ways will render the fence ſtronger, and more immediately fencible againſt cattle. The hedges, raiſed by either method, if deſigned merely as a fence, ſhould be trained only to a moderate height, and kept cloſe and regular by an annual clipping: but ſome ſuffer theſe Elder hedges to grow up high without any trimming, eſpecially at top, permitting them to branch out on each ſide upward, in order to produce large crops of berries, either for private uſe or for ſale.

As to the *Ebulus*, or Dwarf Elder, it is ſometimes admitted in gardens, by way of variety, in the herbaceous collection, and for medical uſe; obſerving, as this perennial multiplies exceedingly by its creeping root, it muſt be occaſionally trimmed at bottom to confine it within moderate limits.

*Method of Propagation, &c.*

All the tree and ſhrub Elders are propagated very expeditiouſly by cuttings of the young yearling ſhoots, and may alſo be eaſily raiſed from ſeed.

By Cuttings.—Cuttings of Elder ſhoots, in lengths of from one or two to five or ſix feet, very readily grow, and autumn, or any time in open weather, from October till ſpring, is the proper ſeaſon for planting them; chuſing cuttings of the laſt year's ſhoots, not thoſe that are green and ſucculent, but ſuch as are become a little woody; obſerving, that if they are deſigned for nurſery-rows, to train occaſionally for different purpoſes, cut them into ſhort lengths of about three joints, planting them in rows two feet aſunder, each cutting two parts of three in the ground: they will readily emit roots in the ſpring, and ſhoot ſtrongly at top in ſummer, training them for the purpoſes wanted, ſome to run up with a ſingle ſtem for ſtandards, others to form buſhy ſhrub-like plants, &c. and in a year or two they may be tranſplanted finally, if required.

Or if intended to form an Elder-hedge, cuttings of the Common Elder, of the above length, may be planted at once, where the hedge is intended, either in a ſingle or double row, about a foot aſunder.

But in ſome particular caſes, large cuttings of from a yard to five or ſix feet long, or more, particularly of the Common Elder, may be planted in any moiſt ſituation, or along ditch-ſides, either to form ſpreading ſtandards, as ſoon as poſſible, for producing plenty of berries, or to form a growing hedge immediately fencible, as it were; in either caſe, planting the cuttings of this length half a yard or two feet deep, and ten or fifteen feet aſunder, for the ſtandards, and one foot apart for the hedge, arranged either ſlanting or chequer-ways, as before obſerved.

The planting of all theſe cuttings may be performed either with a long iron-ſhod dibble, or with an iron crow, or large ſtake driven into the ground to make holes for the long ſets: or, ſometimes, in moiſt, ſoft, deep ſoils, the ends of the cuttings being ſharpened, they may be thruſt into the ground a proper depth, eſpecially the moderate-ſized cuttings.

By Seed.—This mode of propagating Elders is not generally practiſed, they being much more expeditiouſly raiſed from cuttings as above; however, they may alſo be eaſily raiſed in abundance from the ſeed or berries, ſowed in autumn, in beds of common earth, half an inch deep, and managed as other nurſery ſeedling trees.

The ſcattered or ſelf-ſowed ſeeds of theſe trees, falling any where accidentally, either on the ground, in the crevices of old walls, or hollow trees, grow without care or trouble, and produce young plants.

The

The fourth ſort, *Sambucus Ebulus*, is propagated very plenteouſly by parting the roots in autumn.

SAND, See COMPOSTS, EARTH, LOAM, &c.

SANGUINARIA, Puccoon.

It conſiſts of one low, herbaceous, flowering perennial for the flower borders, riſing with a low ſtalk, crowned with octa-petalous flowers.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, two oval concave leaves that fall away.—COROLLA, eight oblong, obtuſe, ſpreading petals.—STAMINA, many ſhort filaments, having ſingle antheræ —PISTILLUM, an oblong compreſſed germen, no ſtyle, but a thick, two-furrowed, permanent ſtigma.—PERICARPIUM, an oblong-bellied bivalvular capſule, having many roundiſh acute ſeeds.

There is but one ſpecies, *viz.*

SANGUINARIA *Canadenſis.*

*Canada Sanguinaria, or Puccoon.*] Hath a tuberous fibrated root, crowned with large, roundiſh, indented leaves, and low, ſlender, leafleſs ſtalks, terminated each with one large, octa-petalous, pure-white flower.

*Varieties.*] Single-flowered,——Semi-double-flowered,—Full-double-flowered.

They are all perennial in root, but annual in ſtalk and leaves; the ſtalks riſing in the ſpring, and flower in April, very ornamentally.

All the varieties are hardy, and proper to intermix with other low ſpring flowers in the fronts of the borders and other compartments; ſhould be planted in autumn, when the ſtalks and leaves are decayed, any time from Auguſt till October, planting them about a foot, or fifteen or eighteen inches from the edge of the border, and about two or three inches deep, and they will all flower in ſpring following.

They are all eaſily propagated by parting the roots in autumn, when the leaves and ſtalks decay.

SANTOLINA, Lavender Cotton.

This genus furniſhes low, under-ſhrubby ever-greens, and herbaceous perennials, for ornamenting the pleaſure-ground and for medical uſe, garniſhed with very ſmall hoary leaves, ſimple and pinnated, in different ſpecies, and compound rayleſs flowers terminating the branches.

Claſs and order. *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, a hemiſpherical, imbricated, general cup.——COROLLA, a compound uniform flower, conſiſting of numerous hermaphrodite funnel-ſhaped florets. —STAMINA, five fine hair-like filaments, and cylindric tubulous antheræ.—PISTILLUM, an oblong tetragonous germen, filiforme ſtyle, and two oblong, depreſſed, truncated ſtigmas.—PERICARPIUM none; each floret is ſucceeded by one four-cornered ſeed, reſting on the common receptacle.

There are four ſpecies; two of them are ſhrubby and two are herbaceous; all, originally, exotics from the ſouth of Europe, but hardy enough to proſper here, in the open ground, all the year.

*Shrubby kinds.*

Conſiſts of two low, ſhrubby, buſhy perennials, compriſing ſome varieties, all durable in root, ſtem, and branches, and retain their leaves the year round, moſtly aſſuming a hoary-whitiſh appearance.

[1]SANTOLINA *Chamæ Cypariſſus.*

*Chamæ Cypariſſus, Dwarf Cypreſs, or Common Lavender Cotton.*] Riſes with a low ſhrubby ſtem, very branchy and buſhy, two or three feet high, very cloſely garniſhed with ſmall taper, quadriſariouſly-indented hoary leaves; and the branches terminated by long peduncles, each ſupporting one compound yellow flower.

[2]SANTOLINA *Roſemariniſolia.*

*Roſemary-leaved Lavender Cotton.*] Riſes with a ſhrubby ſtem, branching numerouſly from one or two feet to a yard high, in different varieties, cloſely garniſhed with ſmall linear hoary leaves, with tuberculated margins, and the branches terminated by long pedunculi, each ſuſtaining one compound pale-yellow flower.

*Varieties of this.*] Greater Roſemary-leaved Lavender Cotton, growing about a yard high —Minor Roſemary-leaved Lavender Cotton, with blunt leaves growing in cluſters—Dark-green leaved—Villoſe hoary-leaved, with a large flower.

The above two ſhrubby Lavender Cottons, and varieties, are retained in our gardens, both as plants of ornament and for medicinal uſe, the leaves, flowers, and ſeeds being proper, particularly the firſt ſpecies.

*Herbaceous kinds.*

[3]SANTOLINA *Anthemoides.*

*Anthemis-leaved Lavender Cotton.*] Hath fibrous perennial roots, herbaceous, very branchy, hairy ſtalks, eight or ten inches high; bipinnated, many-parted downy leaves

leaves like thoſe of chamomile, and the branches terminated by long pedunculi, each ſuſtaining one compound yellow flower.

4 SANTOLINA *Alpina.*

*Alpine Lavender Cotton.*] Hath fibrey perennial roots, herbaceous unbranching ſtalks eight or ten inches high, bipinnated grey leaves, and pedunculi terminated by one yellow flower.

The two ſhrubby ſpecies and varieties, being hardy, low, buſhy ever-greens, are proper ornamental plants for adorning the fronts of ſmall ſhrubbery compartments, where, with their hoary, and lighter and darker-green leaves, in different varieties, they will exhibit an agreeable variety. Some may alſo be potted, to move occaſionally, to embelliſh any particular compartment in aſſemblage.

The herbaceous kinds being alſo hardy, are likewiſe employed occaſionally to cauſe variety in the pleaſure ground.

*Method of Propagation.*

The ſhrubby kinds are propagated the moſt expeditiouſly by ſlips or cuttings of the young ſhoots, and may alſo be raiſed from ſeeds.

By Slips, or Cuttings.——In ſpring, or early in ſummer, ſlip or cut off a quantity of the laſt year's ſhoots, five or ſix inches long, clear away all the lower leaves, then plant them in any ſhady border in rows half a foot aſunder, water them directly, and repeat it in dry weather, and they will root freely and form tolerable plants by autumn, when, or in the following ſpring, they may be tranſplanted with balls, in wider nurſery-rows, &c. or ſome of the largeſt where they are finally to remain.

By Seed.——Sow it in the ſpring, in a bed of light earth, either in ſhallow drills or all over the ſurface, covering it a moderate depth; they will grow the ſame year, and towards autumn, or in the next ſpring, prick them out half a foot aſunder, and after having a year's growth they muſt be tranſplanted to wider diſtances.

The two herbaceous kinds are propagated by parting the roots in autumn; and by ſeed in the ſpring, ſowed in any common earth and raked in, and when the ſeedlings are a little advanced in growth plant them out.

SAPONARIA, Sope-wort.

The plants are herbaceous perennials and annuals, of hardy temperature, ſome of the former being cultivated as flowering plants for variety, &c. producing annual ſtalks two or three feet high, terminated by bunches of pentapetalous flowers.

Claſs and order. *Decandria Digynia.*

*Characters.*] CALIX, is monophyllous, tubular, quinquedented and permanent.—— COROLLA, five petals, narrow and angular below, and broad, obtuſe, and plane above. —STAMINA, ten awl-ſhaped filaments, inſerted alternately into the ungues or tails of the petals, having long incumbent antheræ. —PISTILLUM, a taper germen, two parallel ſtyles crowned with acute ſtigmas.—PERICARPIUM, a cylindric, covered, unilocular capſule, having many ſmall ſeeds.

There are ſeveral ſpecies, one of which only is common to the Engliſh gardens, *viz.*

SAPONARIA *Officinalis.*

*Common Sope-wort.*] Hath a creeping, very ſpreading, perennial root, upright-jointed ſtalks two feet high or more, garniſhed with oval-lanceolate oppoſite leaves, and the ſtalks terminated by umbel-like bunches of purpliſh flowers.

*Varieties.*] Common Single-flowered Sopewort—Double-flowered—Hybrid Sopewort with concave leaves.

This ſpecies grows wild in England, but is ſometimes retained in gardens for variety, particularly the Double-flowered and Hybrid concave-leaved ſort; they all ſucceed in any common ſoil, are durable in root, which ſend up ſtalks annually in the ſpring, and flower in July, continuing in ſucceſſion till September,

The root and leaves are uſed in medicine; and the leaves were formerly uſed inſtead of Sope, and by being boiled in water afford a ſope-like froth, proper for waſhing cloaths; hence the name Sope-wort.

Theſe plants are eaſily propagated by parting the roots, any time in open weather, from autumn till ſpring.

SATUREJA, Savory.

This genus is compoſed of low, under-ſhrubby, and herbaceous aromatic perennials and annuals, for the kitchen-garden, pleaſure ground, and green-houſe, ornamented with ſmall narrow leaves, and ſmall monopetalous ringent flowers at the ſides and termination of the branches.

Claſs and order. *Didynamia Gymnoſpermia.*

*Character.*] CALIX, is monophyllous, erect, tubulous, ſtriated, five-parted at top, and permanent—COROLLA, is monopetalous and ringent, with a cylindric tube, and ſimple chaps, having the upper-lip acutely emarginated,

ginated, and the under-lip three-parted. ——STAMINA, two long and two ſhort filaments, crowned with connivent antheræ.—PISTILLUM, a quadrifid germen, a briſtly ſtyle, having two briſtly ſtigmas.—PERICARPIUM, none, four roundiſh naked ſeeds lodged in the permanent calix.

There are eight or nine ſpecies; the following ſix of which are the ſorts principally known in our gardens, being all exotics from different countries; three of which are hardy, and the others tender, requiring ſhelter of a green-houſe in winter.

*Hardy kinds.*

Conſiſts of three ſpecies; two low under-ſhrubby, and herbaceous perennials, and one annual; all of the aromatic tribe; two of which, Winter Savory and Summer Savory, are eminent pot-herbs, for the kitchen-garden and for medical uſe.

[1]SATUREJA *Montana.* (*Perennial.*)

*Mountain Satureja, commonly called Winter Savory*] Riſes with a low ſhrubby ſtem, branching numerouſly about a foot high; cloſely garniſhed with ſmall linear-lanceolate leaves, many together at the joints; and at the ſides of the branches, ſhort-forked peduncles, ſupporting ſmall whitiſh-red flowers.

This is a fine aromatic perennial, durable in root, ſtem, and branches, and continues in leaf the year round.

[2]SATUREJA *Virginiana.* (*Perennial.*)

*Virginian Savory.*] Riſes with upright, ſtiff, angular ſtalks, branching a foot and half high; ſmall ſpear-ſhaped, pointed, ſtiff leaves, ſcented like penny-royal; and the branches terminated by white flowers in round heads.

[3]SATUREJA *Hortenſis.* (*Annual.*)

*Garden Satureja, or Summer Savory.*] Riſes with upright ſlender ſtalks, branching by pairs a foot or more high; narrow, ſpear-ſhaped, ſtiff, odoriferous leaves, and from the ſides of the branches pale-red flowers, two on each peduncle.

This is a choice aromatic annual pot-herb for the kitchen-garden.

*Green-houſe kinds.*

They conſiſt of three low, under-ſhrubby, ever-green, aromatic perennials, exotics from warm countries, and require ſhelter here in winter.

[4]SATUREJA *Juliana.*

*St. Julian's Thymbra, or True Savory*] Riſes with erect, ſlender, ligneous ſtalks, branching moderately nine or ten inches high; narrow, ſpear-ſhaped, finely-ſcented leaves, and ſmall white flowers, in whorled bunches, round the branches.

[5]SATUREJA *Thymbra.*

*Legitimate Thymbra.*] Riſes with ſhrubby ſtems, branching about two feet high; oblong, acute, odoriferous leaves, and reddiſh flowers, in thick hiſpid whorls round the branches.

[6]SATUREJA *Capitata.*

*Capitated Savory, or Legitimate Thyme.*] Riſes with ſhrubby long ſtalks, branching eight or nine inches high; narrow, carinated, punctated, ciliated leaves, and the branches terminated by capitated ſpikes of white flowers.

All theſe plants flower in June and July; the flowers are ſmall, and each formed of one ringent petal, and in ſome ſorts are ſucceeded by ſeeds in our gardens, particularly the Winter and Summer Savory.

With reſpect to the three hardy ſpecies, the two firſt are perennial, and the third is annual; are all hardy enough to ſucceed in the open ground; the firſt and third ſort merit culture, in every kitchen-garden, as aromatic pot-herbs and as medical plants; and all the three ſorts may alſo be employed to diverſify the compartments of the pleaſure garden, &c. allowing them generally a dry ſoil.

And the tender kinds, requiring ſhelter from froſt, muſt be kept in pots, and placed among the green-houſe exotics, where they will encreaſe the variety, managing them as other ſhrubby exotics of that collection.

*Method of Propagation for all the Sorts.*

The three hardy ſorts are propagated, ſome by ſeed, and the two perennials alſo by ſlips or cuttings of the branches, and by parting the roots.

By Seed.—The Winter and Summer Savory furniſh plenty of ſeed annually in autumn, by which they may be raiſed in abundance, ſowed in the open ground in ſpring; therefore, in the latter end of March, or in April, dig a bed or border of light rich earth, and ſow the ſeed thereon moderately thick, and rake them in evenly, they will ſoon come up; being then careful to give occaſional weeding, and if the plants are any where too much crouded, thin them moderately, and they may either remain where ſowed, thinning them to due diſtances, or may be tranſplanted.

Obſerve,

Obſerve, however, of the Winter Savory, that when the ſeedlings are about two or three inches high, it is eligible to plant out a quantity of the ſtrongeſt, in moiſt weather, in nurſery-rows ſix inches aſunder, to remain till September or ſpring following, then to be tranſplanted with balls where they are finally to remain, in rows a foot aſunder.

But the annual or Summer Savory, may either remain where ſowed, thinning the plants to ſix or eight inches diſtance; or when two inches high, a quantity may be pricked out in beds, in rows the above diſtance; in either caſe the plants will become uſeful in June or July until winter, when they will totally periſh.

Or, when deſigned to have the Winter or Summer Savory remain where ſowed, the ſeeds may be ſowed in ſhallow drills, either in beds, or along the edge of any bed or border by way of an edging.

By Slips, &c.—In the ſpring, or early part of ſummer, the common Winter Savory may be encreaſed plentifully by ſlips or cuttings of the young ſhoots or branches, which very freely take root; therefore, ſlip or cut off a quantity of young ſhoots five or ſix inches long, plant them with a dibble, in any ſhady border, in rows ſix inches aſunder, giving occaſional waterings, and they will be well rooted by September, when they may be tranſplanted with balls when wanted; thoſe for the kitchen-garden plant in rows a foot aſunder, or may be planted in rows along the edge of any border, or other compartment, by way of an edging, as before obſerved of the ſeedlings.

By parting the Roots.—The Virginian Savory, in particular, may be propagated in plenty by parting the roots in autumn or ſpring.

The three tender kinds are very eaſily propagated by ſlips or cuttings in May, June, or July, chuſing ſome of the moſt robuſt young ſide-ſhoots, ſlipping or cutting them off, and plant them in pots, ſeveral in each, which, if plunged in a hot bed, will greatly facilitate their rooting, or, in default thereof, place them under a frame and lights, or ha d-glaſſes, ſhading them from the ſun, and give water, they will ſoon ſhow ſings of growth, when let them enjoy the free air, and, when well rooted, towards autumn tranſplant them in ſeparate pots.

As theſe kinds are apt to dwindle off in three or four years, it is therefore proper to continue raiſing a freſh ſupply of new plants accordingly.

SAXIFRAGA, *Saxifrage.*

This genus comprehends many low, hardy, herbaceous perennials; ſome of which producing ornamental flowers, are proper for the decoration of the pleaſure ground, riſing moſtly with annual ſtalks, ſome a foot high or more, others not ſo much, adorned with ſmall lobated and entire leaves, and terminated with ſmall pentapetalous flowers.

Claſs and order, *Decandria Digynia.*

*Characters.*] CALIX, is ſhort, monophyllous, five-parted, and permanent.—COROLLA, five potent petals.—STAMINA, ten awl-ſhaped filaments, with roundiſh antheræ.—PISTILLUM, a roundiſh acuminated germen, two ſhort ſtyles and obtuſe ſtigmas.—PERICARPIUM, an oval, biroſtrated, or two-beaked, unilocular capſule, containing numerous ſmall ſeeds.

There are upwards of thirty ſpecies of this genus, but not more than five or ſix that are eſteemed for general culture, which are conſidered generally as flowery plants, for variety in the pleaſure-ground, as aforeſaid.

The principal ſpecies are,

[1]SAXIFRAGA *Granulata.*

*Granulous-rooted, Common White Saxifrage.*] Hath a granulous perennial root, being compoſed of numerous ſmall tuberous parts like grains of corn, crowned with many ſmall, kidney-ſhaped, lobated leaves, upright branchy ſtalks a foot high; garniſhed alſo with kidney-ſhaped leaves, and terminated by tufted bunches of numerous white flowers.

*Varieties.*] Common Single-flowered of the meadows--Double flowered of the gardens, being very ornamental.

They flower in April and May, which, when in large tufts, as many ſtalks riſe cloſe together, they make a very ornamental appearance, particularly the Double-flowered variety, and may be diſpoſed either in patches, towards the fronts of borders, or in pots.

[2]SAXIFRAGA *Cotyledon.*

*Cotyledon Saxifrage, with a paniculated and pyramidally branching ſtalk.*] Hath a thick, fibrated, perennial root, crowned with tongue-ſhaped cartilaginous-ſawed leaves, in an aggregate cluſter like houſe-leek, an upright paniculated branching ſtalk, a foot or more high, having all the branches terminated by panicles of white flowers.

*Varieties.*] Common Paniculated Cotyledon Saxifrage——Pyramidal Saxifrage, branching

branching almoſt from the bottom a foot and half high, with the branches diminiſhing gradually in length upward, and all of them terminated by ſpreading white flowers; the whole forming a beautiful pyramid.

[3]SAXIFRAGA *Umbroſa.*

*Umbroſe Saxifrage, commonly called London Pride, or None-ſo-pretty* ] Hath a fibrated perennial root, crowned with ob-oval nearly retuſed leaves in circular heads, having cartilaginous crenated margins; and upright, ſlender, naked, paniculated ſtalks a foot or more high, terminated by panicles of whitiſh flowers ſpotted with red, having alſo red piſtils.

This is an old inhabitant of our gardens, and was formerly planted for edgings, though it is rather improper for that purpoſe, but being diſpoſed in tufts about the borders, it will effect a proper variety.

[4]SAXIFRAGA *Hypnoides.*

*Cuſhion Saxifrage, commonly called Lady's Cuſhion.*] Hath a fibrated perennial root, crowned with narrow trifid leaves, many trailing ſpreading ſhoots, garniſhed with entire and trifid leaves, and upright, almoſt naked ſtalks, but a few inches high, terminated by ſmall bunches of whitiſh flowers.

The trailing ſhoots and leaves of this plant forming a cloſe roundiſh bunch like the ſhape of a cuſhion or pillow, hence it is commonly called Lady's Cuſhion.

[5]SAXIFRAGA *Punctata.*

*Spotted Saxifrage.*] Hath a fibrous perennial root, crowned with roundiſh indented leaves, in a circular cluſter, on long foot-ſtalks, and upright, ſlender, naked ſtalks a foot high, terminated with panicles of white flowers ſpotted with red punctures.

[6]SAXIFRAGA *Hirſuta.*

*Hairy Saxifrage.*] Hath a fibrous perennial root, crowned with heart-ſhaped-oval retuſe leaves, with cartilaginous crenated edges, and hairy leafleſs ſtalks, near a foot high, terminated by panicles of white flowers, having a few red ſpots.

Theſe ſix ſpecies are all hardy perennials, generally conſidered as flowery plants; but the firſt three ſorts are the moſt commonly cultivated, and have the greateſt merit as plants of ornament; however, all the ſorts may be employed for variety, and diſpoſed in patches towards the fronts of flower-borders, &c. and the firſt and ſecond ſort are alſo often planted in pots to move to any place occaſionally, more particularly the Granulous Double White Saxifrage, and the Cotyledon Pyramidal Saxifrage, both of which demand ſingular attention for their ornamental flowers.

They are all durable in root, and ſome ſorts alſo retain their leaves all the year; the Granulous Saxifrage, however, is deciduous, and all the ſorts produce flower-ſtalks annually in the ſpring, flowering, in the different ſorts, from April till June; the firſt ſpecies and variety generally flower in April and May, and the others in May and June.

All the ſorts are very eaſily propagated by off-ſets of the roots and heads, which they furniſh abundantly.

The firſt ſort multiplies exceedingly by its granulous roots, which, towards autumn, when their ſtalks and leaves decay, may be divided, not too ſmall, but in little bunches, and let them be planted again directly, ſome in the open borders, &c. and ſome in pots, forming a ſmall hollow in the earth an inch deep, in which depoſit the bunch of roots, covering them the ſame depth with earth; and being thus planted in bunches, they will ſend up ſeveral ſtalks in a cluſter together, and exhibit a large tuft of flowers.

The ſecond and third ſpecies multiply very faſt by ſide off-ſets from the head or crown of the plant, each furniſhed with roots, which may be parted or ſeparated in autumn, or early in the ſpring, and planted where they are finally to remain, obſerving to plant ſome of the Cotyledon pyramidal ſort in pots, and the others in patches towards the front of the borders.

The other three ſorts are alſo propagated by off-ſets, and parting the roots, in autumn or ſpring.

SCABIOSA, Scabious.

This genus of plants conſiſts of herbaceous annuals, biennials, and perennials, for ornament and variety in the pleaſure-ground, and ſhrubby perennials for the green-houſe, garniſhed with leaves of different forms in the different ſpecies, and terminated with numerous aggregate heads of flowers, each head compoſed of many ſmall florets contained in one general calix.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX, a ſpreading many-leaved general cup, containing many florets, each floret having a double calix.—COROLLA, each floret of the aggregate is monopetalous, tubulous, and cut into four or five parts at top.—STAMINA, four awl-ſhaped filaments in each floret, having oblong incumbent

cumbent antheræ.—PISTILLUM, a germen under each floret, and a ſlender ſtyle, crowned with an obtuſe, obliquely emarginated ſtigma. —PERICARPIUM, none; a ſingle, oblong, oval ſeed to each floret crowned with the calix.

There are many different ſpecies of Scabioſa; a few only are in eſteem for general culture, principally as plants of ornament and variety, conſiſting of ſome hardy herbaceous annuals, biennials, and perennials; and three ſhrubby exotics for the green-houſe.

*Hardy herbaceous kinds.*

This head comprehends ſome remarkable flowery annuals and biennials, and ſome perennials for variety, riſing with upright branchy ſtems, two or three feet high or more, garniſhed with leaves below, and numerous flowers at top; obſerving, the firſt two are annuals, the reſt perennial; but the annual kinds are the moſt generally known, and cultivated as ornamental plants.

[1]SCABIOSA *Atropurpurea. (Annual,* &c.)
*Dark-Purple Sweet Indian Scabious.*] Hath a fibrous annual root, crowned with a large tuft of oblong leaves, variouſly jagged and cut on the edges, and often into ſegments, and upright ſtems, branching numerouſly, on every ſide, three feet high or more; and from the ſides and ends of the branches, numerous dark-purple, and other coloured flowers, in the varieties, having all quinquefid florets and awl-ſhaped receptacles.

*Varieties.*] Common Dark-purple Sweet Scabious — Pale-purple-flowered — Red-flowered—White-flowered—Black-flowered —Hen and Chicken-flowered, having ſeveral ſmall flowers ariſing from the ſides of the main one—Striped-flowered, &c.

They all flower in June, continuing in plentiful ſucceſſion till September, forming a very ornamental appearance, and are ſucceeded by abundance of ripe ſeeds in autumn.

All the varieties of this ſpecies are very hardy, and may be conſidered both as annuals and biennials, for, being raiſed from ſeed forward in the ſpring, they will run up to ſtalk and flower the ſame year, and generally periſh the following winter; but if not ſowed till ſummer, they produce only leaves that year, encreaſe in ſtrength, and remain vigorous till ſpring following, when they will ſhoot up vigorouſly into very ſtrong branchy ſteme, and produce an amazing quantity of flowers from June till autumn, and furniſh plenty of ſeeds, then totally periſh root and ſtem towards winter, ſo that a freſh ſupply muſt be annually raiſed from ſeed both as annuals and biennials.

[2]SCABIOSA *Stellata. (Annual, &c.)*
*Starry Spaniſh Scabious.*] Hath a fibrous annual root, crowned with oblong leaves, variouſly cut on the edges, and upright ſtems branching numerouſly about a yard high, garniſhed with oblong, finely cut leaves, and the upper parts ſupporting numerous purple flowers compoſed of quinquefid ſtar-ſhaped florets with roundiſh receptacles, flowering in July.

This ſort may alſo be treated both as an annual and biennial, as obſerved of the former ſort; but more commonly as an annual.

[3]SCABIOSA *Arvenſis.*
*Common Field Scabious.*] Hath fibrous perennial roots, upright hiſpid ſtems, branching three feet high, garniſhed with pinnatifid leaves, with the lobes at a diſtance, and blue flowers, having radiated florets.

*Varieties.*] With reddiſh flowers—Purple-flowered, &c.

It grows wild in the fields and meadows in England, but is ſometimes cultivated for variety.

[4]SCABIOSA *Succiſa.*
*Succiſa, or Devil's Bit (Morſus Diaboli.)* Hath a thick, ſhort, downright root, terminated abruptly as if bit off, crowned with oval, ſpear-ſhaped, entire leaves; upright ſingle ſtalks two feet high, with the branches growing near, and terminated by blue flowers with equal quadrifid florets.

This grows naturally in England, &c. in paſtures and woods.

[5]SCABIOSA *Alpina.*
*Alpine Blue Scabious.*] Hath a ſtrong, fibrous, perennial root, ſending up ſeveral ſtrong ſtems, branching four or five feet high, garniſhed with pinnated leaves of four or five pair of ſpear-ſhaped ſawed lobes; and from the upper parts, whitiſh-yellow drooping flowers, having quadrifid equal florets.

[6]SCABIOSA *Argentea.*
*Silvery Oriental Scabious.*] Riſes with low ſlender ſtems, dividing into ſpreading branches, pinnated ſilvery-white leaves, with ſpear-ſhaped lobes, and the branches terminated by long, naked, ſmooth peduncles, ſuſtaining ſmall pale flowers with quinquefid florets.

[7]SCABIOSA *Gramina.*

*Graſs-leaved Silvery Scabious of the Helvetian Mountains.*] Hath a fibrous perennial root, ſending up herbaceous ſtalks half a yard high, garniſhed below with very narrow, lanceolate, entire ſilvery leaves; and the upper part ſupporting pale-blue flowers, having quadrifid florets.

All theſe herbaceous kinds are very hardy plants, that ſucceed in any common ſoil of a garden, and in almoſt any ſituation.

But the two annual ſorts are the moſt generally known and cultivated, and have the greateſt merit as ornamental flowery plants.

*Tender Shrubby kinds for the Green-houſe.*

Compriſes three ſhrubby ſpecies, exotics from warm countries, as mentioned in their titles, and require ſhelter here in winter, ſo muſt be kept in pots and placed among the green-houſe plants.

[8]SCABIOSA *Cretica.*

*Cretan Shrubby Scabious.*] Riſes with a ſhrubby ſtem, branching two or three feet high; long, ſpear-ſhaped, whitiſh, entire leaves, numerouſly in cluſters, and the branches terminated by fine blue flowers, having quinquefid florets.

*Variety.*] Auricula-leaved.

[9]SCABIOSA *Africana.*

*African Shrubby Scabious.*] Riſes with a ſhrubby ſtem, branching four or five feet high; oval-ſpear-ſhaped cut leaves, and the branches terminated by fleſh-coloured flowers, having quinquefid florets.

*Varieties.*] Rough crenated-leaved—Finely cut-leaved—Woolly-leaved.

[10]SCABIOSA *Rigida.*

*Rigid or Stiff-leaved Shrubby Æthiopian Scabious.*] Riſes with a ſhrubby ſtem, branching two or three feet high; ſpear-ſhaped, ſerrated, ſtiff, ſhining leaves, and the branches terminated by whitiſh flowers, having quadrifid, nearly-radiated florets, and obtuſe calicinal ſcales.

All the above ſpecies of *Scabioſa* flower commonly in June, July, and Auguſt, and ſome continue in ſucceſſion till autumn, generally producing the flowers upon long foot-ſtalks ſingly, each flower being an aggregate of ſeveral ſmall quadrifid or quinquefid florets, placed all within one common calix, forming together a moderately large flower, which, in ſome ſpecies, are prodigiouſly numerous, and very ornamental, particularly the two annual kinds; and which two ſorts furniſh plenty of ſeeds in autumn, likewiſe moſt of the other ſpecies.

The merit of theſe plants is, ſome for ornament others for variety.

The two annual kinds, in particular, producing abundance of ornamental flowers, very conſpicuouſly, two or three months in ſummer, are choice furniture for all the common flower compartments, and merit culture in every garden; being raiſed annually from ſeed in ſpring and ſummer, in the open ground, and thence planted out to remain to flower, which, in thoſe of the ſpring ſowing, will be effected the ſame year, but thoſe raiſed in ſummer do not flower till the ſummer following.

The herbaceous perennial kinds may be introduced in the compartments of large gardens for variety.

And the ſhrubby kinds, being potted and placed among the green-houſe exotics, they will effect a good variety, and flower ornamentally in ſummer.

*Propagation and Culture of all the Sorts.*

Firſt, the Annual and Biennial Sorts.—The two firſt ſpecies, being hardy annuals and biennials, may be raiſed plentifully from ſeed annually, in a bed or border of common earth, and, as formerly noticed, may be conſidered both as annuals and biennials, and may be treated accordingly, more particularly the *Scabioſa Atropurpurea* and varieties; obſerving, that if intended to raiſe them as annuals, for flowering the ſame year, they ſhould be ſowed in the ſpring, about March, on a warm border, or, to bring them as forward as poſſible may ſow them in a hot-bed; and being planted out about the borders, in May or beginning of June, they flower the ſame year in July or Auguſt, though not near ſo ſtrong as plants raiſed the year before as biennials: therefore, in order to have ſtrong flowering plants, it is moſt eligible to ſow a principal ſhare in June, to encreaſe in growth all ſummer without running up to ſtalks, and ſtand the winter, for flowering early next ſummer, in which they will produce much ſtronger ſtems, branching more numerous and ſtrong, and produce a greater number of flowers: however, it may be proper to ſow both in ſpring for flowering the ſame year, and in June for next year's flowering; but it is more particularly proper to ſow ſome of the Starry Scabious in ſpring as annuals.

Obſerve,

Obſerve, in ſowing theſe two annual ſorts, that the firſt ſort in particular may be ſowed for tranſplantation, chuſing a bed of light moiſt earth; ſow the ſeed evenly and rake it in; and when the plants are two or three inches high, prick out ſome of the ſtrongeſt, in moiſt weather, where they are to remain to flower, eſpecially the ſpring-ſowed plants; but thoſe deſigned for next year's flowering ſhould be planted in nurſery-beds, in rows ſix or eight inches aſunder, giving neceſſary waterings and weeding, and they will grow fine large plants by autumn, when, or in the following ſpring, tranſplant them with balls of earth to the places where they are to flower.

But the Starry Scabious may either be ſowed in ſpring for tranſplantation, or in patches about the borders, to remain where ſowed, to flower.

Perennial Sorts.—The five hardy, herbaceous, perennial Scabiouſes, are all very eaſily propagated, both by ſeeds ſowed in any bed or border of common earth in the ſpring, and the ſeedlings planted out where they are to remain, and by parting the roots in autumn.

Shrubby kinds.—All the three ſhrubby ſorts are expeditiouſly propagated by planting ſlips or cuttings of the branches in ſpring or ſummer; if in ſpring, plant them in pots, and place them either in a hot-bed or under ſhelter of glaſſes; but in ſummer they may be planted in the full ground, ſhaded and watered; and in either method they will root tolerably well the ſame year, and towards autumn may be potted off ſeparately, and managed as other ſhrubby exotics of the green-houſe.

SCANDIX, Shepherd's Needle, Garden Chervil, &c.

This genus is compoſed of herbaceous annuals and a perennial, for the kitchen-garden and for variety, riſing with finely-divided leaves, and erect ſtalks from one to four or five feet, terminated by umbels of flowers.

Claſs and order. *Pentandria Digynia.*

*Character.*] CALIX, umbellate flower; the general umbel long, and compoſed of a few rays, and the partial umbels of many, and the ſmaller umbellæ only have a five-leaved involucrum—COROLLA, a deformed, radiated, general umbel, having both hermaphrodite and female florets, compoſed of five heart-ſhaped petals.—STAMINA, five ſlender filaments with roundiſh antheræ.—PISTILLUM, an oblong germen, two permanent ſtyles and obtuſe ſtigmas—PERICARPIUM, none, a long two-parted fruit, having two awl-ſhaped furrowed ſeeds.

There are ſeven or eight ſpecies, one of which only is common to the Engliſh gardens, known by the name of Garden Chervil, a fine aromatic, eſteemed as a ſallad and ſoup herb. There is alſo a perennial ſort ſometimes cultivated for variety.

[1]SCANDIX *Cerefolium.* (*Annual*)

*Cerefolium, or Garden Chervil.*] Hath a fibrated annual root, crowned with many finely-divided leaves, of an aromatic flavour, and upright ſtalks, one or two feet high, terminated by umbels of white flowers, with lateral umbels ſitting cloſe, ſucceeded by oval, awl-ſhaped, ſhining ſeeds.

This is an annual plant, but remains in leaf all winter, and is cultivated as a culinary herb for winter and ſpring ſervice; it may alſo be continued for uſe the year round, by ſowing ſeveral times from February till September, becauſe the ſpring and ſummer ſowing run up to ſeed the ſame year, but the autumn ſowing will remain green until ſpring before it runs.

[2]SCANDIX *Odorata.* (*Perennial.*)

*Odoriferous, Great, Perennial Chervil, or Sweet-fern.*] Hath a thick, fibrated, perennial root, of a ſweet aromatic taſte, crowned with large divided leaves, reſembling fern, and upright hollow ſtalks, four or five feet high, terminated by large umbels of white, very fragrant flowers, ſucceeded by long, angular, furrowed ſeeds.

Theſe plants are both very hardy; the firſt is an annual, and the other a perennial. The annual ſort is in eſtimation both for ſallads and ſoups, as before obſerved, and the leaves are the uſeful part; the young leaves of the ſecond were alſo ſometimes uſed formerly, but rarely now, ſo is only retained in ſome gardens to encreaſe the variety in the pleaſure ground, and the annual ſort for the kitchen-garden only, which will grow in any ſoil and ſituation.

They run up to ſtalk in ſpring, flower in May or June, and the ſeeds ripen in July.

As to the culture of the *Cerefolium*, or Garden Chervil, it is by ſeed annually, obſerving, if it is required moſt part of the year, the ſowing ſhould be continued every month till Auguſt or September, as before hinted; but if required only for winter and early ſpring uſe, an autumn ſowing in Auguſt or begin-

beginning of September, will be ſufficient, and the plants coming up ſoon after remain uſeful from October till March or April. The ſeed may be ſowed any where, either broad-caſt and raked in, or in ſhallow drills ſix or eight inches aſunder; and in either caſe the plants are to remain where ſowed, being careful to give occaſional weeding, which is all the culture they require, and they will ſoon be fit to cut for uſe.

The ſecond may alſo be raiſed from ſeed, and plant out ſome of the plants about the large compartments, and when once thus raiſed they will remain ſeveral years, and from its ſcattered ſeeds many young plants will riſe in the adjacent ground.

SCHINUS, Indian Maſtic tree.

It conſiſts of two ſhrubby ever-green exotics for the green-houſe and ſtove, riſing eight or ten feet high, adorned with pinnated many-lobed leaves, and the branches terminated by bunches of pentapetalous flowers.

Claſs and order. *Dioecia Decandria.*

*Characters.*] CALIX, dioecious flowers, having monophyllous, acutely five-parted cups, that of the females being permanent. —COROLLA, five oval petals in the males, and five oblong ones in the female flowers; thoſe in both ſexes being petiolated.—STAMINA, ten filiforme ſpreading ſegments, having roundiſh antheræ.——PISTILLUM, a roundiſh germen, no ſtyle, but three oval ſtigmas.—PERICARPIUM, a globular trilocular capſule, having three ſeeds.

There are only two ſpecies, which being natives of Peru, and other parts of the Indies, require ſhelter of a good green-houſe here in winter, ſo muſt always be kept in pots.

[1]SCHINUS *Molle.*

*Molle-tree of Cluſius, or Peruvian Maſtic-tree.*] Riſes with a woody ſtem, branching numerouſly eight or ten feet high, with pinnated leaves of ten or twelve pair of ſawed lobes and an odd one, which is much the longeſt; and the branches terminated by looſe bunches of whitiſh flowers.

[2]SCHINUS *Areira.*

*Areira, or Braſilian Maſtic-tree.*] Hath a woody ſtem, branching eight or ten feet high, with pinnated leaves of ten or twelve pair of entire lobes, and an odd one, all of equal length; and at the ſides and ends of the branches ſmall cluſters of whitiſh flowers.

Both theſe ſpecies are ſhrubby, durable in root, and top, and retain their leaves the year round; and being natives of hot countries, require ſhelter here of a good green-houſe in winter; or, if ſheltered in a ſtove, two or three winters whilſt young, it will be an advantage to the plants; however, they both ſucceed tolerably with the culture of common green-houſe exotics. They being pretty ever-greens, with finely pinnated leaves, merit a place in the collection of our tender exotics, in which they will effect a good variety; let them, therefore, be cultivated in pots of rich earth, and placed among the plants of the above department.

They are propagated by ſeed obtained from abroad, alſo by layers and cuttings.

Sow the ſeeds in the ſpring, in pots of rich earth, and plunge them in a hot-bed, managing them as other tender ſeedling exotics.

Layers of the young branches in the ſpring will be well rooted in one year.

And cuttings of the young ſhoots, planted in ſpring, in pots, and plunged in a hot-bed, will readily emit roots in ſix or eight weeks.

SCILLA. Squill, or Sea-Onion, Starry Hyacinth, &c.

This genus comprehends a fine collection of hardy, bulbous-rooted, flowery perennials, for adorning the flower borders, having moſtly very large tunicated and ſolid bulbous roots, crowned with long narrow leaves, and erect flower ſtalks, annually; in ſome ſorts two or three feet high, in others but a foot, and ſome but ſix or eight inches, ornamented at top with pyramidal and conic cluſters of hexapetalous ſtarry flowers.

Claſs and order. *Hexandria Mongynia.*

*Characters.*] CALIX, no cup.—COROLLA, ſix oval petals, ſpreading out like the figure of a ſtar.—STAMINA, ſix awl-ſhaped filaments, crowned with oblong, incumbent antheræ.—PISTILLUM, a roundiſh germen, ſimple ſtyle, and ſingle ſtigma.—PERICARPIUM, a nearly oval, three furrowed, trilocular, trivalved capſule, containing many roundiſh ſeeds.

There are about eight ſpecies, all of the bulbous-rooted tribe, ſeven of which are originally from diſtant countries, as Spain, Portugal, France, &c. and the eighth grows wild in ſome parts of England, &c. and all the ſorts are hardy enough to ſucceed in our gardens in the full ground.

[1]SCILLA *Maritima.*

*Maritime Squill, or Common Sea Onion.*] Hath a large oval tunicated onion-like bulbous root, ſending up long narrow leaves, near half a yard in length, and an upright

right naked ſtalk, two or three feet high, having the upper half adorned with a pyramidal thyrſe of white ſtarry flowers appearing early in ſummer.

*Varieties.*] Red-rooted—White-rooted.

This ſpecies is a maritime plant, inhabiting the ſandy ſea-ſhores of Spain and other warm countries, but the bulbs are ſent here annually for medical uſe, and are planted in many gardens as flowery plants for curioſity.

[2]SCILLA *Lilio-Hyacinthus.*

*Lily Hyacinth.*] Hath a ſquamous, or ſcaly, bulbous, lily-like, yellow root, crowned with oblong lily-like leaves, half a foot long or more, and an upright ſlender ſtalk, about a foot high, terminated by many ſtar-ſhaped blue flowers, appearing in June.

[3]SCILLA *Peruviana.*

*Peruvian Hyacinth, or Hyacinth of Peru.*] Hath a large, oblongiſh, bulbous brown root, ſending up ſeveral carinated ſpreading leaves, ſix or eight inches long, broad at the baſe, decreaſing to a point at top, and upright, thick, ſucculent ſtalks, ſix or eight inches high, terminated by a conical corymbus cluſter of deep-blue ſtarry flowers, appearing in May.

*Variety.*] With white flowers.

[4]SCILLA *Italica.*

*Italian, Blue-ſpiked, Starry Hyacinth.*] Hath a roundiſh, white, bulbous root; longiſh leaves with obtuſe points, and erect ſtalks, eight or ten inches high, terminated by a hemiſpherical corymbus of pale-blue flowers, appear in April.

[5]SCILLA *Amœna.*

*Fine Byzantine Hyacinth.*] Hath a large, roundiſh, bulbous, purpliſh root, ſending up ſeveral narrow, carinated, ſpreading leaves a foot long, and upright purpliſh ſtalks eight or ten inches high, ornamented upward with fine ſky-blue ſomewhat drooping flowers, riſing laterally in alternate order, appearing in March or April,

[6]SCILLA *Bifolia.*]

*Two-leaved Early Star Hyacinth.*] Hath a ſmall, roundiſh, ſolid, bulbous root, ſending up only two narrow leaves, about ſix inches long, and a ſlender ſtalk half a foot high, terminated by a few, nearly-erect, blue, ſtarry flowers, appearing early in March.

*Variety.*] With white flowers.

[7]SCILLA *Autumnalis.*

*Autumnal Squill, or Engliſh Starry Hyacinth.*] Hath a ſmall, round, white, bulbous root, very ſlender linear leaves, ſix inches long, and upright ſlender ſtalks, half a foot high, adorned at top with a corymbus of ſmall, blue, ſtarry flowers, having naked peduncles, riſing over one another, the length of the flower, appearing early in September. This grows naturally in many parts of England, &c.

All theſe ſpecies of *Scilla* are bulbous perennials, durable in root, but annual in leaves and ſtalks, which riſe immediately from the root: in ſome ſorts the leaves ſpring up in autumn, and remain green all winter, and decay in ſpring, particularly the firſt, third, and laſt ſort, and ſome others: and in ſome the leaves and flower-ſtalks appear at the ſame time. The ſtalks are generally naked or leafleſs, and terminated by the flowers, which conſiſt univerſally of ſix oval petals, ſpreading open, in a ſtar-like manner, with great uniformity and beauty, exhibiting a good ornamental appearance; and in moſt of the ſorts are ſucceeded by ripe ſeeds in autumn, by which all the ſorts may be raiſed; but more expeditiouſly by off-ſets of the roots annually, when the leaves and ſtalks decay.

They being all of hardy temperature, may be employed as flowery plants to adorn the pleaſure ground, diſpoſed either in patches about the borders, &c. or depoſited in beds by themſelves.

Obſerve, they ſhould generally be removed for tranſplantation when their leaves and flower-ſtalks are decayed, when the roots may be taken up, and either planted again directly, where wanted, or kept till autumn, &c. though the autumnal ſort ſhould be planted early, in order that they may blow the ſame year in autumn; planting all the ſorts about three or four inches deep, or in proportion to the ſize of the bulb. See BULBUS.

The bulbs of all the ſorts may be had, moderately cheap, at moſt of the nurſery-grounds and ſeed-ſhops.

### *Method of Propagation, &c.*

The propagation of all the ſorts is by off-ſets of the roots; the firſt ſpecies, however, being a native of ſandy ſea-ſhores, it encreaſes but ſparingly in gardens, but is obtained plentifully from abroad. All the others furniſh plenty of off-ſets, which may be ſeparated every other year, if required, when their leaves, &c. decay, as practiſed for other bulbous roots.

They

They may all be propagated alſo by ſeed, though this is a tedious method, as the ſeedlings are ſeveral years before they blow: they ſhould be ſowed in autumn, in light earth, an inch deep, obſerving, the ſame method of ſowing and culture practiſed for the Common Hyacinths, &c. See HYACINTHUS.

SCORPIURUS, Caterpillar.

The plants of this genus are hardy, herbaceous, trailing annuals, cultivated in the pleaſure ground more as plants of ſingularity than beauty, for the oddity of their caterpillar-like ſeed-pods; they riſing with procumbent ſtalks, garniſhed with oblong ſimple leaves, and papilionaceous flowers, ſucceeded by contorted pods reſembling green caterpillars.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, inflated, and cut into five acute ſegments.—COROLLA, is papilionaceous; the ſtandard, roundiſh, emarginated, ſpreading, and reflexed; the wings are looſe and nearly oval, and a ſemi-lunulated, pointed, erect keel, two-parted below.—STAMINA, ten diadelphous filaments, with ſmall antheræ.—PISTILLUM, an oblong taper germen, a riſing inflexed ſtyle, terminated by a punctura or point.—PERICARPIUM, an oblong, coriaceous, revoluted, rough pod, of many tranſverſe cells, each containing one ſeed.

There are four ſpecies, natives moſtly of the ſouth of Europe, but grow freely here, in our gardens, in the open borders.

The ſpecies are,

[1]SCORPIURUS *Vermiculata.*

*Common, Vermiculated, Uniflorous Caterpillar.*] Riſes with trailing herbaceous ſtalks, a foot or more long, garniſhed with oblong ſpatula-ſhaped leaves; and at the axillas long pedunculi, each ſupporting one papilionaceous yellow flower, ſucceeded by oblong twiſted pods, covered on every ſide with obtuſe ſcales.

[2]SCORPIURUS *Muricatæ.*

*Muricated Biflorous Caterpillar.*] Riſes with thick- trailing, herbaceous ſtalks, a foot and half long, garniſhed with oblong, broad, obtuſe leaves, and at their axillas long pedunculi, each ſuſtaining two papilionaceous yellow flowers, ſucceeded by oblong, very twiſted, rough pods, having the outſide armed with obtuſe oculi.

[3]SCORPIURUS *Sulcata.*

*Sulcated Triflorous Caterpillar.*] Riſes with ſlender, trailing, herbaceous ſtalks, a foot long, oblong obtuſe leaves, and each pedunclе ſupporting three yellow flowers, ſucceeded by ſlender moderately-twiſted pods, armed on the outſide with acute diſtinct ſpines.

[4]SCORPIURUS *Subvilloſa.*

*Subvilloſe Quadriflorous Caterpillar.*] Riſes with trailing herbaceous ſtalks, a foot and half long, oblong obtuſe leaves, and long pedunculi, each ſuſtaining four yellow flowers, ſucceeded by oblong, ſlender, very contorted pods, armed on the outſide with ſharp ſpines in cluſters.

All theſe four ſpecies of *Scorpiurus* are hardy herbaceous annuals, that riſe from ſeed annually in the ſpring; are all of trailing growth, extending their ſtalks along upon the ground, having one leaf at each joint, and at the wings of the leaves ariſe the flowers, being univerſally papilionaceous, appearing in June and July, and are ſucceeded by oblong pods, variouſly contorted and ſtained, ſo as to bear a very great reſemblance to large caterpillars, apparently feeding on the plants, effecting a curious ſingularity, thoſe of the firſt ſort in particular, which are the largeſt, moſt conſpicuous, and caterpillar-like; however, all the ſorts form an agreeable variety, and they all furniſh plenty of ripe ſeeds in autumn.

Theſe plants, therefore, merit a place in the collection of hardy annuals, principally for the ſingularity of their caterpillar-like ſeed-pods, and being diſpoſed in patches about the borders they will exhibit an eligible variety.

They are propagated by ſeed in the ſpring, which ſucceeds in the full ground, and ſhould generally be ſowed in patches about the borders, where the plants are deſigned to remain, as they do not ſucceed ſo well by tranſplantation; therefore, form ſmall patches in the different compartments, ſowing ſeveral ſeeds in each patch, half an inch deep; and when the plants are come up an inch or two high, thin them to two or three in each place, and clear out weeds, which is all the culture they require, and they will flower in June, and exhibit their pods abundantly all the latter part of ſummer.

SCORZONERA, Viper's Graſs, but commonly called *Scorzonera.*

The plants are herbaceous perennials, biennials, and annuals, moſtly of the carrot-rooted kind, one of which, in particular, producing large eatable roots, is cultivated as a kitchen-garden eſculent: they riſe moſtly with

with long, narrow, graſſy leaves from the root, and erect tall ſtalks, ſurmounted by large compound flowers.

Claſs and order. *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, a long, imbricated, nearly-cylindric, general cup, containing many florets.—COROLLA, many, tongue-ſhaped, quinquedented, imbricated, hermaphrodite florets, the outer ones being the longeſt.—STAMINA, five ſhort filaments, having cylindric antheræ.—PISTILLUM, an oblong germen, filiforme ſtyle, and two reflexed ſtigmas.—PERICARPIUM, none, a ſingle oblong ſeed in each floret, ſitting on the receptacle within the connivent calix.

There are ſeveral ſpecies, but of which there is only one cultivated for uſe, as an eſculent and medical plant; the others having but little merit their culture is not attended to, except in ſome curious botanic gardens merely for variety.

The cultivated ſort therefore is,

SCORZONERA *Hiſpanica.*

*Spaniſh Viper's Graſs, or Common Scorzonera.*] Hath a long, downright, carrot-ſhaped eatable root, covered with a brown ſkin, but white and milky within, crowned with ſeveral long, narrow, entire, ſlightly-ſawed leaves, terminating in a long acute point; and when it ſhoots for ſeed, runs up with an erect, robuſt, branchy ſtem, a yard or more high, garniſhed with amplexicaulous leaves, like the lower ones, and all the branches terminated by large, compound, bright-yellow flowers.

The root is the uſeful part, being in perfection in autumn and winter, and is boiled and eaten like carrots, &c. and is by many greatly eſteemed.

This ſpecies, though of a perennial nature in the root, yet, for general uſe, it ſhould be commonly treated as an annual or biennial; for, being raiſed from ſeed in the ſpring, the roots will be fit for uſe in the following autumn, and remain in perfection till next ſpring, when they will ſhoot up ſtalks for flower and ſeed, and become hard, ſticky, and unfit for uſe, ſo ſhould be thrown away, and a freſh ſupply raiſed from ſeed.

The general propagation of this plant is by ſeed annually, in any open light ſpot of ground, ſowed the latter end of March or beginning of April, not earlier, leſt the plants fly up to ſeed the ſame year, before the roots acquire perfection: having, therefore, made choice of an open ſpot of ground in the kitchen-garden, and at the proper ſeaſon digged it one good ſpade deep at leaſt, then let the ſeed be ſowed either broad-caſt, all over the ſurface, thinly, and raked in, or may draw ſhallow drills, ten or twelve inches aſunder, and ſow the ſeeds therein, and rake the mould evenly over them half an inch thick; in either method the plants will riſe in two or three weeks; obſerving, when they are a little advanced in growth, let them be thinned and cleaned from weeds, by hoeing them in dry weather, cutting out the plants to eight or ten inches diſtance, and cutting away all weeds between them; thus they will grow freely, and their roots continue encreaſing in ſize till September, when they will have acquired their full ſize, diſcoverable by their leaves beginning to decay; at which token of maturity, may begin to draw them for uſe.

The roots may either remain in the ground, and drawn as they are wanted, or may be taken wholly up in autumn, when their leaves decay, and preſerved in ſand all winter, that they may be ready at all times, eſpecially in froſty weather, when they cannot be dug out of the ground.

To ſave ſeed of this ſpecies, let ſome of the plants remain where ſowed, when they will ſhoot up in the ſpring, and produce plenty of ſeed in autumn.

SEDUM, Leſſer Houſe-leek, Orpine, and Stone-crop.

This genus is compoſed principally of hardy herbaceous ſucculents for variety, riſing with annual ſtalks, ſome erect, a foot or two high, ſome but a few inches, and ſome are of trailing growth; adorned with fleſhy leaves, and terminated with bunches of pentapetalous flowers.

Claſs and order, *Decandria Pentagynia.*

*Characters.*] CALIX, is erect, acute, five-parted, and permanent.—COROLLA, five, ſpear-ſhaped, plane, ſpreading petals, and five nectariums, formed each of one emarginated ſcale, inſerted in the outſide of the germen.—STAMINA, ten awl-ſhaped filaments, having roundiſh antheræ.—PISTILLUM, five oblong germens, terminating in ſlender ſtyles, crowned by obtuſe ſtigmas.—PERICARPIUM, five acuminated ſpreading capſules, opening longitudinally, and are filled with many ſmall ſeeds.

There are many ſpecies of *Sedum*, conſiſting of herbaceous perennials and annuals, inhabitants moſtly of dry ſterile places, as hills,

rocks, and tops of walls and buildings; and a few of the perennials only are retained in gardens for variety, and ſome as medical plants, moſt of which are ſucculent both in ſtalk and leaves; ſome riſing with erect ſtalks half a yard high, others not ſix inches, and ſome trail along the ground, as above hinted, and are moſtly deciduous plants, one ſpecies only being evergreen.

The moſt noted ſpecies are,

[1]SEDUM *Telephium.*

*Telephium, Common Orpine, or Livelong.*] Hath a perennial root, compoſed of many knobbed tubercles, ſending up erect, round, ſucculent ſtalks, branching half a yard or two feet high, garniſhed with oblong, plane, ſerrated, ſucculent leaves, and the ſtalks terminated by a leafy corymbus of flowers, of different colours in the varieties.

*Varieties.*] Purple-flowered Orpine—— White-flowered—Broad-leaved.

This ſpecies is an inhabitant of woods and dry places in England, &c. but has been long a reſident of gardens for variety and medical uſe: conſidered as a medicinal plant, it has great virtue in eaſing pains both of green wounds and old ſores, the leaves being peeled or bruiſed, and applied to the part affected; and it is ſaid they will alſo cure corns.

There is a ſingularity in this plant, that the ſtalks being cut in ſummer, and faſtened upright in a room, they, by their ſucculency, will continue ſhooting a long time, only by ſprinkling them with water once a week.

[2]SEDUM *Anacampſeros.*

*Anacampſeros, or Decumbent Evergreen Italian Orpine.*] Hath a fibrous perennial root, decumbent or trailing ſtalks, wedge-ſhaped entire leaves, and the ſtalks terminated by a corymbus of purple flowers.

[3]SEDUM *Rupeſtre.*

*Rock Sedum, or Stone-crop of St. Vincent's Rock.*] Hath ſlender, trailing, purple ſtalks; ſhort, thick, awl-ſhaped, ſucculent, glaucous leaves in cluſters, quinquefariouſly imbricated round the ſtalks, and the ſtalks terminated by roundiſh cymoſe bunches of bright yellow flowers.

It grows naturally on St. Vincent's Rock near Briſtol, and other rocky places in Europe.

[4]SEDUM *Aizoon.*

*Aizoon, or Siberian Yellow Orpine.*] Hath a tuberculated, fibrous, perennial root; many upright, round, ſucculent ſtalks, a foot high; lanceolate, plane, ſerrated, thickiſh leaves; and the ſtalks terminated by a cloſe-ſitting cymoſe cluſter of bright yellow flowers.

[5]SEDUM *Reflexum.*

*Reflexed, Small Yellow Sedum, or Prick Madam.*] Hath a ſlender, fibrous, perennial root; ſmall trailing ſucculent ſtalks, garniſhed with thick, awl-ſhaped, ſucculent leaves ſparſedly, the lower ones recurved, and the ſtalks terminated by reflexed ſpikes of bright yellow flowers.

It grows naturally on old walls and buildings in England, &c.

[6]SEDUM *Acre.*

*Acrid Sedum, Common Stone-crop of the Wall, or Wall Pepper.*] Hath ſmall fibrey roots, very ſlender ſucculent ſtalks, four or five inches high, very ſmall, ſub-oval, gibbous, erect, alternate leaves, cloſe together; and the ſtalks terminated by trifid-cymoſe bunches of ſmall yellow flowers.

This ſort grows abundantly on rocks, old walls, and tops of buildings, almoſt every where, which often appear covered with the flowers in ſummer: it merits culture in pots of rubbiſhy earth, and in patches in dry ſtony banks, and in rock-work, or on tops of walls, &c. where it will encreaſe into large tufts, and exhibit a pretty variety when in flower.

Its leaves, &c. are of an acrid biting quality.

[7]SEDUM *Sexangularis.*

*Sexangular Stone-crop.*] Hath a fibrey perennial root; thick, ſhort, ſucculent ſtalks; ſmall, ſub-oval, gibbous, erect leaves cloſe together, arranged ſix ways imbricatim, and the ſtalks terminated by bunches of yellow flowers.

It grows on rocky and other dry places in England, &c.

[8]SEDUM *Album.*

*White Stone-crop.*] Hath fibrey perennial roots; trailing ſlender ſtalks, ſix or eight inches long; oblong, obtuſe, ſeſſile, ſpreading leaves; and the ſtalks terminated by branchy cymoſe bunches of white flowers.

This grows on old walls, rocks, and buildings in England, &c.

[9]SEDUM *Hiſpanicum.*

*Spaniſh Sedum.*] Hath fibrous perennial roots, crowned with cluſters of taper, acute, ſucculent leaves; ſlender ſucculent ſtalks, four or five inches high, garniſhed alſo with taper leaves, and terminated by downy cymoſe cluſters of white flowers.

All

All theſe ſpecies of *Sedum* are hardy, herbaceous, ſucculent perennials, durable in root, but moſtly annual in ſtalk, &c. which, riſing in ſpring, flower in June, July, and Auguſt, in different ſorts; the flowers conſiſting univerſally of five ſpreading petals, generally crowning the ſtalks numerouſly in corymbus and cymoſe bunches and ſpikes, appearing tolerably conſpicuous, and are ſucceeded by plenty of ſeeds in autumn, by which they may be propagated, alſo abundantly by parting the roots, and by ſlips or cuttings of the ſtalks in ſummer; in all of which methods they readily grow and ſpread very faſt into tufted bunches.

They being all of ſucculent growth, they conſequently delight moſt in dry ſoils, or in any dry rubbiſhy earth, and moſt of them will grow upon rocks and buildings.

Theſe plants merit culture for variety, but particularly the firſt five or ſix ſorts, and the firſt ſort alſo as a medicinal plant, indulging them generally with a light dry ſoil, as they are commonly the moſt durable in any dry rubbiſhy earth, either in the full ground or in pots, alſo in rocks, ruins, and the tops of buildings, with only a ſmall portion of ſoil at firſt to root in.

They may therefore be diſpoſed for variety, ſome in any dry or rubbiſhy bank or border, and ſome in pots of dry ſoil, to move to different compartments occaſionally; in both caſes, planting either ſlips of the root in the ſpring or autumn, or ſlips or cuttings of the young ſhoots in ſpring or ſummer, they will all readily grow and encreaſe faſt enough; the common Orpines will alſo ſucceed in any common dry ſoil in any of the borders.

They may likewiſe be employed as rock-plants to embelliſh rock-work, ruins, and the like places, either planting the roots, or cuttings of the ſhoots, in a little mud, or any moiſt ſoil at firſt, and place it in the crevices, &c. they will ſoon root and fix themſelves, and ſpread about very agreeably; and all the Stone-crop kinds in particular may may be made to occupy the tops of walls and buildings, by planting them as aboveſaid in a little mud or moiſt earth, previouſly placed on the wall, &c. they will readily root and eſtabliſh themſelves without farther care.

*Method of Propagation for all the Sorts.*

All the ſorts are eaſily propagated by ſlipping the roots, at almoſt any time of the year; likewiſe by ſlips or cuttings of their ſhoots in ſpring and ſummer, more particularly all the Orpine kinds; but cuttings of all the ſorts will very readily grow; and as to the Stone-crop kinds, ſhoots of them may be eaſily ſlipped in ſpring and ſummer with roots to their bottom; the ſame may alſo be often practiſed to moſt of the other ſpecies: obſerving, in all the methods of propagation, the ſlips and cuttings may either be planted in the nurſery way till well rooted, or planted at once where they are to remain, in the places and manner before mentioned.

They may alſo be propagated by ſeeds ſowed in any dry ſoil, or in the crevices of buildings, &c.

SEMEN, the Seed, being the eſſence of the fruit of every vegetable, containing the future plant in miniature, and conſiſts of the following eſſential parts.

*Corculum, or Punctum Vitæ* The little heart, the point of life, or embryo of the future vegetable, being the ſmall point or ſpeck, placed in the center of the Seed, between the cotyledons or lobes, and attached thereto, and is diſtinctly viſible in the bean and moſt other leguminous ſeeds: conſiſts of two parts, the *roſtellum* and *plumula*, the former being the radical or deſcending part that ſtrikes downwards, and becomes the root, the other is the aſcending part, that ſhoots upward and become the ſtem and branches, &c.

*Cotyledon or Side Lobes.* Being the ſide periſhable lobes of the Seed, which involve, and for ſome time nouriſhes the *corculum* or embryo plant: theſe lobes are generally two in number, very conſpicuous in the bean and other ſeeds of the leguminous tribe, particularly if they have been previouſly laid in earth or water.

After the Seeds have been committed to the earth, the *corculum* or *punctum vitæ*, begins to germinate, and the cotyledons expand, burſt open the outer cover, and riſes gradually out of the earth in form of leaves, commonly called the Seed-leaves, exhibiting the firſt viſible formation of the infant plant, accompanying it for ſome time after its eruption from the earth, till the firſt proper leaves are formed in the center of the vegetable, and advanced a little in growth, then the lobes or ſeminal leaves becoming uſeleſs, wither and decay.

Moſt plants have two cotyledons or Seed-leaves, (*Dicotyledones*) particularly almoſt all the tribe of fibrous-rooted herbaceous plants,

and all trees and ſhrubs; but ſome have only one cotyledon, (*Monocotyledones*) as in moſt of the bulbous plants of the liliaceous tribe, riſing out of the ground like a ſheath; and ſome ſeeds have no cotyledon at all (*Acotyledones*), ſuch as the ferns, moſſes, flags, and funguſes.

Other parts of the Seed are:

*Ala or Wing*. Many Seeds are winged, or furniſhed with a thin membrane or film, and, by its flying, helps to diſperſe them, as in fir, birch, maple, aſh, elm, hops, and numerous other ſorts.

*Coronulla or Little Crown*. Many Seeds are crowned, and ſome ſurrounded with a pappus, *i. e.* a feathery or hairy down, particularly many of the compound tribe and others, for the purpoſe of diſſemination, being framed for flying like a ſhuttlecock, ſo as to be eaſily tranſported by the wind to very conſiderable diſtances from the parent plant; hawk-weed, grounſel, and dandelion furniſh examples.

But numerous ſorts of Seeds are ſimple, *i. e.* have neither wing nor pappus.

The number, form, ſize, and ſubſtance of Seeds are extremely various in different plants.

In point of number it conſiſts of from one to ſeveral hundred, or even thouſands in each ſeed-veſſel; for ſome plants have only one, ſome two, three, four, or many Seeds, and ſome are of amazing fertility, amounting to many hundreds, as for inſtance, a ſingle Seed-veſſel of tobacco often contains about one thouſand Seeds; that of white poppy, eight thouſand; and the whole produce of one tobacco-plant is upwards of forty thouſand, though ſome have computed the number above three hundred thouſand; and the produce of a ſingle ſtalk of ſpleen-wort is eſtimated at upwards of a million of Seeds.

As to form, Seeds are either round, oval, kidney ſhaped, heart-ſhaped, angular, &c.

With reſpect to ſize, Seeds are of numerous ſizes in different plants, from the large ſize of cocoa nuts down to the minute Seeds of creſſes, moſſes, and others much ſmaller.

And as to ſubſtance, ſome Seeds are ſoft or fleſhy, ſome membranous, and ſome are of a hard bony nature, as in all the nuciferous tribe.

Seeds are covered or naked. Covered Seeds (*Angioſpermia*) are ſuch as are contained in ſome veſſel, either of the capſule, pod, berry, apple, or cherry kind: and naked Seeds (*Gynoſpermia*) are thoſe that are not contained in any veſſel, but lodged in the receptacle, or in the bottom of the calix.

The vaſt variety of ways nature has provided for the diſſemination of ſeeds is truly wonderful; in moſt plants the fruit or veſſels, containing the ſeed, are raiſed above the ground either by erect firm ſtems, or often by climbing ſtalks, ſo that the fruit, being elevated from the ground, it may be more eaſily ſhaken by the wind, which often blows Seeds to a great diſtance; for the ſame reaſon that ſpecies of ſeed-veſſel called a capſule, opens at the top, that the Seeds may be more eaſily diſſeminated. Many Seeds being winged, as before obſerved, are by that means ſpread far and near by the winds; theſe wings conſiſting either of a thin membrane or film, as in the fir, birch, maple, elm, aſh, hops, &c. as formerly hinted; or of a fine feathered or hairy down, beard, or tail, as in moſt of the compound plants, alſo in the ſcabious, valerian, and many others, whereby they are eaſily wafted to a great diſtance to different ſoils and territories. Some ſeed-veſſels are endued with a remarkable elaſticity, by which means they dart their Seed, with an elaſtic force, to ſome conſiderable diſtance, ſuch as touch-me-not, and ſpirting cucumber, &c. Many Seeds and ſeed-veſſels being armed with hooks, hairs, &c. by which they attach themſelves to animals, and are thereby diſperſed, ſuch as in carrot, hemp agrimony, burdock, &c. Likewiſe Seeds of many ſorts, being devoured by birds, they void them entire, often in different parts, at a diſtance, and they grow. Berries, and other pulpy fruit, being eaten as food, the Seeds, or kernels of many ſorts often paſs through unhurt, and falling to the ground often grow. Seeds are alſo often diſſeminated by rivers, torrents, and all running waters and tides, hence often conveyed many hundred leagues from their native ſoil, and caſt upon a very different climate, to which, however, they ſometimes, by degrees, render themſelves familiar.

The duration of Seeds, in reſpect to the retention of their germinative property, is very conſiderable: for inſtance, the cucumber, melon, and gourd, often retain their vegetative power eight, ten, or twelve years; and it is ſaid, the *mimoſa* or ſenſitive plant, will retain the principle of life thirty or forty years; on the other hand, the greater number of ſeeds will not keep good above one or two years, and many will not grow well if.

if more than one year old, and ſome Seeds require to be ſowed ſoon after they are ripe, or they will not grow till the ſecond year; others, unleſs ſowed ſoon after they are gathered, will not grow at all, as is often the caſe with the coffee-berries. It is however obſervable, of almoſt all ſorts of Seeds, that being ſowed the firſt year, they generally riſe ſooner and ſtronger than older Seeds; for which reaſon it is adviſable to chuſe principally new Seeds, not more than one year old, if poſſible, of all ſorts of plants and trees, only a few excepted, ſuch as cucumbers and melons in particular, of which, Seeds of two or three years old, or more, are often preferable, becauſe plants raiſed from new Seed are apt to run vigorouſly to ſtem without producing much fruit.

All Seeds produced in dry capſules, pods, and other dry Seed-veſſels, keep much longer in their ſaid veſſels than if taken out; though it is probable that moſt Seeds will retain their germinative faculty longeſt in the bowels of the earth, when they have been accidentally buried a conſiderable depth out of the reach of the influence of the ſun and air. And it has been obſerved of corn-ſallad in particular, which by accident have been buried three feet deep in the ground thirty years, and the ſoil being turned up that depth to the top, they have growed freely; the ſame has alſo been obſerved of many other Seeds, which by chance have been immerſed in the ground ſeveral feet deep; and in the bottom of wells, vaults, ponds, and ditches, that have not been ſtirred for many years, as may be judged from circumſtances; for when occaſion required the ſoil to be thrown to the top, and expoſed to the ſun and air, many plants have riſen that had not been remembered to have been ſeen thereabouts before, or at leaſt for many years paſt.

Likewiſe moſt ſorts of Seeds, if ſowed too deep, remain inactive, and ſome never grow at all; others, nevertheleſs, preſerve their growing property; and when the ground is again freſh ſtirred, ſuch of the Seeds as happen to be moved nearer the ſurface will often come up, which ſhews the power of the ſun and free air in promoting vegetation in Seeds and plants.

Seeds, therefore, ſhould never be ſowed too deep, and always in proportion to their ſize; from about a quarter, or half an inch deep, for the ſmaller Seeds, to about one or two inches for the middling and large kinds of Seeds. See SOWING OF SEEDS.

The germination or growth of Seeds, after being regularly ſowed or committed to the earth a proper depth, is in ſome ſorts very quick, and others ſlow; as for inſtance, creſſes, muſtard, turnip, and many others, come up in a few days; ſome other ſorts in one, two, or three weeks, as in moſt of the eſculents of the kitchen-garden; and numerous others of the herbaceous tribe, though parſley, and ſome others, often remain inactive a month or ſix weeks, and ſome ſorts lie a year or two in the ground before they germinate. As to the tree and ſhrub Seeds, ſome will riſe in a month or ſix weeks, or leſs time, others require two or three months to vegetate, and ſome ſorts lie a whole year at leaſt before they begin to grow, ſuch as the hawthorn, holly, and moſt other of the very hard bony ſeeded kinds; all of which, both in the herbaceous and woody tribe, is generally hinted in the culture of the reſpective ſorts under their proper genera. See alſo GERMINATIO.

For particulars in regard to the various methods of ſowing of Seeds, ſee SOWING OF SEEDS.

SEMPERVIVUM, Live-ever, or Houſe-leek.

The plants are of the ſucculent tribe, herbaceous and ſhrubby, conſiſting of low, hardy, herbaceous, ever-green perennials, for variety in the pleaſure ground, &c. and medical uſes, and ſhrubby ever-green ſucculents for the green-houſe collection, adorned with roundiſh and oblong, thick, fleſhy, ſucculent leaves all the year, and the ſtalks terminated by bunches of polypetalous flowers.

Claſs and order. *Dodecandria Polygynia.*

*Characters.*] CALIX, is concave, cut into many acute ſegments, and permanent.—— COROLLA, from ſix to ten or twelve oblong, ſpear-ſhaped, acute, concave petals—STAMINA, twelve awl-ſhaped filaments, with roundiſh antheræ.——PISTILLUM, twelve germina, placed circularly, terminating in the like number of ſpreading ſtyles, crowned with acute ſtigmas.—PERICARPIUM, about twelve oblong, compreſſed, circularly-placed capſules, pointed outward and opening on the inſide, filled with many ſmall roundiſh ſeeds.

There are about ſix or ſeven ſpecies, four or five of which are hardy herbaceous plants, and two are ſhrubby ſucculent exotics for the green-houſe.

*Hardy*

*Hardy Horbaceous kinds.*

They are low herbaceous ever greens, with ſucculent leafy heads cloſe to the crown of the root, ſending up flower-ſtalks annually, in ſome a foot high, others not half ſo much; one ſort (*Common Houſe-leek*) grows naturally in England, &c. on buildings, or barren hills, the others in mountainous parts on the continent of Europe, but are all hardy enough to grow here, any where either in the full ground or in pots, or on tops of walls, buildings, or rock-work, &c.

[1]SEMPERVIVUM *Tectorum.*

*Houſe Sempervivum, or Common Houſe-leek.*] Hath a fibrous perennial root, crowned with many ovaliſh, pointed, ciliated, ſucculent leaves, in roundiſh heads, cloſe to the earth, having many ſpreading off-ſets; and upright, round, ſucculent, reddiſh ſtalks a foot high, terminated by reflexed ſpikes of ſpreading red flowers, in July and Auguſt.

This is the Common Houſe-leek, which grows naturally on the tops of buildings and barren hills in England, and moſt countries in Europe; and we may ſee it growing in tufts on the tops of ſheds, and other low buildings, almoſt every where, with hardly any ſoil in which to root, for the off-ſets being planted at firſt in a little lump of any ſoil, and placed on the tiles or thatch of any building or on the coping of a wall, they will readily ſtrike and multiply into large bunches without any culture.

This ſpecies, being of a very cooling quality, is uſed againſt the St. Anthony's fire, ſhingles, burns, ſcalds, and inflammations, &c.

[2]SEMPERVIVUM *Globiferum.*

*Globiferous Siberian Houſe-leek.*] Hath a fibrous root, crowned with numerous, narrow, ciliated, ſucculent leaves in compact globular heads, producing many globular off-ſets; and erect, round, ſucculent ſtalks, ſix or eight inches high, terminated by yellowiſh flowers.

*Variety.*] With Red flowers.

This ſpecies produce numerous ſmall globular off-ſets, which being thruſt off by the larger heads, and falling on the ground, &c. take root freely of themſelves, and become proper plants.

[3]SEMPERVIVUM *Arachnoideum.*

*Arachnoide Alpine Houſe-leek, or Cob-web Sedum.*] Hath fibrous roots, crowned with ſhort, narrow, ſucculent leaves in ſmall heads, having many hair-like threads, interſecting one another from leaf to leaf, reſembling a ſpider's web; and erect, round, ſucculent ſtalks, ſix inches high, terminated by ſpikes of bright red flowers ranged moſtly along one ſide.

[4]SEMPERVIVUM *Montanum.*

*Mountain Helvetian Houſe-leek.*] Hath fibrous roots, crowned with oblongiſh, pointed, ciliated, ſucculent, ſmooth leaves, in expanded open heads, producing very ſpreading off-ſets; and erect ſucculent ſtalks, eight or ten inches high, terminated by ſpikes of deep-red flowers.

All theſe herbaceous *Sempervivums* are very hardy ever-green perennials, formed of roundiſh cluſters of ſucculent leaves cloſe to the ground, &c. remaining green all the year, and from the center of the heads of leaves ariſe the flower-ſtalks annually, flowering moſtly in July and Auguſt, ſucceeded by ripe ſeeds in autumn.

They are all hardy enough to grow any where in any dry ſoil or rubbiſhy banks, or in pots, and the tops of buildings, rock-work, &c.

The ſmalleſt off-ſet, being planted at firſt in a ſmall portion of any ſoil, will grow and increaſe ſurpriſingly.

*Tender ſhrubby kinds.*

Theſe conſiſt of two ſhrubby ſucculent exotics, with ſtrong erect ſtems, terminated by heads of numerous ſucculent leaves, and ſpikes of flowers, and being natives of hot countries require ſhelter of a green-houſe here in winter.

[5]SEMPERVIVUM *Arboreum.*

*Tree Houſe-leek.*] Riſes with an upright, thick, fleſhy, tree-like, ſmooth, branching ſtem, ſix or eight feet high, with the branches terminated by large cluſtering heads of ſpear-ſhaped, bright-green leaves; and, from the center of the heads, large pyramidal ſpikes of bright yellow flowers, in autumn and winter.

*Varieties.*] Variegated-leaved Tree Houſe-leek, which is a very curious variety of a fine ornamental appearance — White-flowered. Both the varieties flower very ornamentally, and the flowers continue long in beauty.

It is a native of Portugal, Crete, and the Cape of Good Hope.

[6]SEMPERVIVUM *Canarienſe.*

*Canary Shrubby Houſe-leek.*] Riſes with an upright, ſucculent, rugged ſtalk, half a yard or more high, appearing ragged with the rudiments

diments of paſt foliage, having the top crowned by large globular heads of retuſe ſucculent leaves; and from the center of the head a long pyramidal ſpike of greeniſh flowers, in June and July.

All the above ſix ſpecies of *Sempervivum* retain their leaves the year round, which, in all the ſorts, are thick, fleſhy, and ſucculent, and generally collected many together into round heads; and from the center of the heads ariſe the peduncle or flower-ſtalk, terminated by the flowers in ſummer and autumn, each flower compoſed of from about eight or ten to twelve petals, ſpreading out every way in a ſtar-like manner, exhibiting a good ornamental appearance, and are ſucceded by ripe ſeeds in autumn.

All the ſorts being of a very ſucculent nature, are the moſt proſperous and durable in the drieſt light ſoils; and the hardy ſorts, in particular, thrive on the tops of walls, buildings, and rock-work.

The four hardy ſorts ſucceed any where, in the open air, all the year, and may be planted for variety in any dry rubbiſhy bank, or in pots of the like ſoil; alſo upon rock-work, the tops of walls, and buildings; for as they increaſe exceedingly by off-ſets on every ſide, and theſe being ſlipped off at almoſt any time, and planted in a little ſtiff mud or ſtrong earth, placed on any building, &c. they will grow freely, and ſoon multiply into large bunches, as may be obſerved of the Common Houſe-leek.

The two tender ſhrubby ſorts, requiring ſhelter in winter, muſt be kept in pots of light ſandy earth, or any dry rubbiſhy ſoil, and placed among the green-houſe plants, where they will exhibit a conſpicuous variety at all times of the year; but more eminently the *Sempervivum Arboreum* and variety, managing them as other ſucculents of the green-houſe collection, being particularly careful to water them but ſparingly in the winter, as too much moiſture is deſtructive of tender ſucculents in that ſeaſon. See GREEN-HOUSE PLANTS.

*Method of Propagation, &c.*

All the four hardy *Sempervivums* are very expeditiouſly propagated by their off-ſet heads, which may be readily ſlipped off with roots, or even without any they will ſucceed; planting them in any light dry ſoil, or rubbiſh, as before obſerved; and if on buildings or rock-work, &c. lay a little mud or ſtiff ſoil thereon in patches, in which plant the ſlips, and they will grow and flouriſh without farther trouble.

The two green-houſe kinds are propagated by cuttings of the branches and by ſeed.

By Cuttings.—The firſt of theſe two ſorts in particular is eaſily propagated by cuttings of the ſmaller branches, any time from April or May till July, either with or without the aid of hot-beds, though, if planted early, they may be greatly forwarded by the aſſiſtance of artificial heat; however, in any of the ſummer months they will readily take root in a bed, or pots of natural earth, in the open air; obſerving, in taking off the cuttings, if they appear very ſucculent in the cut part, it is eligible to lay them in the dry a few days to ſkin over, previous to planting; then either plant them in pots of dry light ſoil, or in a bed of common light earth till rooted; in either method allow them occaſional ſhade from the ſun, and ſometimes moderately watered in very dry weather, eſpecially thoſe in pots; they will thus be well rooted in two or three months, and may then be potted ſeparately in middling pots, and placed among the other green-houſe exotics.

By Seed.—The Canary Houſe-leek, in particular, producing ſeed in tolerable plenty in our gardens, it may be alſo propagated by ſowing the ſeed in autumn, or early in ſpring, in pots of light earth, placing them in a frame to have ſhelter from froſt, but expoſed in mild weather; and as the warm ſeaſon advances the plants will begin to appear, which, when an inch or two high, prick them in ſeparate ſmall pots, and manage them afterwards as other ſucculents of the green-houſe.

SERRATULA, Saw-wort.

It conſiſts principally of tall, hardy, herbaceous, flowery perennials, for ornamenting the pleaſure garden; riſing with annual ſtalks from two to ſeven or eight feet high, adorned with pinnatifid and entire leaves in the different ſpecies, and the ſtalks terminated by ſcaly heads of compound flowers.

Claſs and order. *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, an oblong, imbricated, general cup, compoſed of many ſpear-ſhaped, acute, ſmooth ſcales.—COROLLA, a uniform compound flower, compoſed of many hermaphrodite funnel-ſhaped florets, with an inflexed tube and ventricoſe limb, cut

into five parts.—STAMINA, five ſhort hair-like filaments, with cylindric antheræ.—— PISTILLUM, an oval germen, filiforme ſtyle, and two oblong reflexed ſtigmas.—PERICARPIUM, none, each floret ſucceeded by one oval ſeed crowned with down.

The principal ſpecies, in the Engliſh gardens, are the following, the firſt of which is a native of England, the others of different parts of America, but are all of hardy growth, conſiſting both of fibrous and tuberous-rooted perennials,

[1]SERRATULA *Tinctoria.*

*Tinctturaceous Common Saw-wort.*] Hath a fibrous perennial root, upright annual ſtems, two feet high, lyre-ſhaped pinnatifid leaves, having the terminal lobe the largeſt, and the ſtalks terminated by ſcaly heads of purple and white flowers in the different varieties.

This grows naturally in woods and meadows in England, &c. and is ſometimes cultivated for variety.

[2]SERRATULA *Noveboracenſis.*

*New-York Saw-wort.*] Hath a fibrated perennial root, upright channelled ſtalks, ſeven or eight feet high, oblong, lanceolate, ſerrated, pendulous leaves, downy underneath, and the ſtalks terminated by heads of purple flowers.

[3]SERRATULA *Glauca.*

*Glaucous Maryland Saw-wort.*] Hath a fibrous perennial root, upright, channelled, purple ſtalks, ſix or ſeven feet high, oblong-oval, acuminated, ſawed, glaucous-coloured leaves, and the ſtalks terminated by corymbus bunches of purple flowers, having roundiſh cups.

[4]SERRATULA *Scarioſa.*

*Scarioſe-flowered Virginia Saw-wort, or Tuberous Knap-weed.*] Hath a tuberous perennial root; upright, ſtrong, channelled ſtalks, three or four feet high; ſpear-ſhaped entire leaves; and the ſtalks adorned upward with many purple flowers, riſing laterally on obtuſe peduncles, having alſo rough ſcaly calixes.

[5]SERRATULA *Squarroſa.*

*Squarroſe Virginia Saw-wort, or Tuberous Melancholy Thiſtle.*] Hath a tuberous perennial root, an upright ſtalk, near a yard high, linear, or very narrow ſtiff leaves, and the ſtalk adorned upward with purple flowers, riſing laterally and ſitting almoſt cloſe in ſquarroſe, or rough, ſcaly, acuminated cups.

[6]SERRATULA *Spicata.*

*Spiked Virginia Saw-wort.*] Hath a tuberous perennial root, upright ſingle ſtalks, two or three feet high; linear leaves, ciliated at the baſe; and the ſtalks terminated by long ſpikes of cloſe-ſitting purple flowers, riſing laterally.

[7]SERRATULA *Prælta.*

*Prælatous Peach-leaved Virginia Saw-wort.*] Hath a fibrous root, upright branching ſtalks, four or five feet high, oblong, ſpear-ſhaped, ſerrated, ſpreading leaves, hairy underneath, and the branches terminated by looſe bunches of purple flowers.

All theſe ſpecies of *Serratula* are perennial in root but annual in ſtalk, which, riſing in ſpring, flower in June, July, and Auguſt, in the different ſorts; the flowers are univerſally compound, conſiſting of many tubular florets in large ſcaly calixes, and in moſt of the ſorts are tolerably conſpicuous and ornamental; but thoſe of the American kinds are not always ſucceeded by good ſeeds in our gardens; they, however, multiply faſt enough by the root.

Theſe plants being moſtly of erect tall growth, are proper ornaments for the compartments of large gardens, and to interſperſe in ſhrubberies, and along the verges of woods, walks, &c.

*Method of Propagation.*

They are propagated by parting the roots, and by ſeeds.

By Parting the Roots.—All the ſorts ſend out off-ſets from the root, but the fibrous-rooted kinds the moſt abundantly, and the roots may be ſlipped or divided, either in autumn, when the ſtalks decay, or in ſpring before new ones begin to ſhoot up, though if done early in autumn they will flower much ſtronger the following year.

By Seed.—All the ſorts may alſo be raiſed from ſeeds; but the tuberous ſorts, in particular, not encreaſing very plentifully by roots, they muſt be often raiſed from ſeeds, ſowed in autumn or early in ſpring, in an eaſt border, in ſhallow drills; and when the ſeedlings are two or three inches high, prick ſome of the thickeſt out in nurſery-rows till autumn, then plant the whole finally to remain.

SEXUS *Plantarum*, Sexes of Plants.

The different Sexes of plants, with regard to their being male, female, or hermaphrodite, is determinable by their flowers and fruit only.

All

All plants, from the largeſt tree down to the ſmalleſt moſſes and fungi, and other the moſt minute vegetables, are furniſhed with flowers either viſible or inviſible, or concealed; but in the greater number viſible and conſpicuous: and in either caſe the flowers are the genitals or generative organs of all vegetables, being furniſhed with male, female, and hermaphrodite fructifications, ſometimes on different plants of the ſame genus, and ſometimes both male and female on different parts of the ſame plant; but the greater part of the vegetable kingdom is of the hermaphrodite kind, having both male and female organs (*ſtamina and piſtillum*) all within the ſame flower: all which genital parts, or fructifications in the above different ſexes, being eſſentially neceſſary for the purpoſe of generation, as ſerving the important office of fecundation to impregnate the embryo fruit, and fertilize the ſeed. See GENUS, and FLOS; alſo FOEMINA FLOS, MASCULUS FLOS, HERMAPHRODITUS FLOS, FRUCTIFICATIO, &c.

Every flower, however large or minute, is furniſhed with genitals, *i. e. ſtamina* and *piſtillum*, either in the ſame or in different plants and flowers, &c.

For example:

Male plants are ſuch as produce male-flowers only, which male-flowers are thoſe that are furniſhed only with the *ſtamina*, conſiſting of the filaments and antheræ, being the male genitals, but want the *piſtillum*, or female organs.

Female plants being productive of female flowers only, ſuch as are furniſhed with the *piſtillum*, conſiſting of the germen, ſtyle, and ſtigma, the female fructifications, but want the *ſtamina*, or male genitals.

And hermaphrodite plants are thoſe which produce only hermaphrodite flowers, being ſuch as contain both *ſtamina* and *piſtillum*, the male and female organs, all within the ſame calix and corolla, as prevail in the greater number of the vegetable creation.

Likewiſe obſerve,

Monoecious, or androgynous plants, are ſuch as produce both male and female flowers diſtinct, ſituated on different parts of the ſame vegetable, as in the cucumber, melon, and many other. See the Claſs MONOECIA.

Polygamous plants. Such that bear the ſeveral ſexes of flowers, as hermaphrodite and male and female flowers together. See the Claſs POLYGAMIA.

The exiſtence of the Sexes of plants was greatly diſputed by many of the ancient botaniſts and others; but whoever is ſtill doubtful in that point, will but examine the curious ſtructure of flowers, and make ſome experiments, will ſoon be convinced, that the flowers of all plants are furniſhed with proper generative organs; and that the male genitals, the filaments, and antheræ, being furniſhed with a certain ſubtle powder impregnates therewith the *piſtillum* of the females, and fertilizes the embryo fruit and ſeed in the germen, or ovary; ſo that when the flower fades, the fruit ſwells, and the ſeeds become fertile, as may be experienced in early cucumbers in frames by carrying the antheræ of the male bloſſom and touch the ſtigma of the female flower therewith, ſo as to leave ſome of its golden powder on the ſtigma, or female organ, which infallibly impregnates the germen, or miniature fruit, and it will ſoon viſibly ſwell and increaſe faſt in magnitude, furniſhed alſo with fertile ſeed, which, without being previouſly fecundated by the male duſt, generally prove ſterile, or barren, and if ſowed they would not germinate.

So that if we were to remove all the male flowers of cucumbers, or melons, erroneouſly called falſe-bloſſoms, before they blow, we render the females, or fruit-bloſſoms, abortive.

Likewiſe, if flowers of any ſort were caſtrated, or deprived of the male organs, the filaments and antheræ, before they ripen their impregnating powder of the antheræ, the female parts would become ſterile, or, at leaſt, the fruit would either not ſwell at all, or but very imperfectly, and the ſeeds would remain unfertilized, and if ſowed they would not grow.

For although ſome ſorts of plants may probably by chance produce a ſort of imperfect fruit and ſeeds, without the immediate vicinity of male flowers, the ſame as a hen may lay eggs without the congreſs of a cock, yet for want of being fertilized with the male ſperm, neither will the ſeeds grow, nor the eggs bring forth chickens.

Linnæus, in his definitions of the Sexes of plants, ſays, the calix is the marriage-bed in which the male and female organs conſummate the nuptials of plants, and in which theſe tender organs are cheriſhed and defended from external injuries; and the corolla, or petals, are the curtains cloſely ſurround-

ing the genitals, in order to reſiſt ſtorm, rain, or cold; but when the ſun ſhines bright they expand freely, both to give acceſs to the fecundating duſt and to the ſun's rays, to promote the fecundating faculty of the ſaid powder, in acting with due effect on the ſtigma and ſtyle: for the filaments are the ſpermatic veſſels of the males, by which the juice ſecreted from the plant is carried up to the antheræ in form of a fine powder, which is the pollen, or male duſt, anſwering to the male ſperm of animals, or the roe of fiſhes; for although it is dry, it is more eaſily conveyed by the winds, or air, to the ſtigma, or female organ, where it is moiſtened, thence proceeds to the ſtyle, which is the vagina, or tube through which the effluvia, or male duſt paſſes to the germen, or ovary, and there impregnates the fruit or ſeed, which immediately becomes fertile, and then the petals of the flower withers, and the fruit and ſeed grow faſt to perfection.

Thus we need not wonder, that in the vegetable kingdom ſuch numbers of plants are of the hermaphrodite race, *i. e.* the flowers having both male and female organs within the ſame calix and corolla; though in the animal kingdom there are very few of the hermaphrodite kind, for here one ſex can eaſily go to another, whereas plants are fixed to one ſpot and cannot go from it, ſo that the male and female parts of fructification being within the ſame cover, the ſecundation is more eaſily effected by nature.

Other plants again having the male and female parts in different flowers, have their ſituation on the plants and their genitals ſo wonderfully diſpoſed by nature that the ſecundation is effected by the winds and certain inſects conveying the male duſt from the antheræ to the female organs.

Moſt plants appear the moſt beautiful when in flower; but when the genitals of the flower have performed their natural function, the flower ſoon after fades, and many plants gradually loſe much of their former ſplendor, and numerous ſorts, after flowering and ripening ſeeds, either decay wholly, as in all the annual and biennial tribe, and ſome only die down to the root, as in numerous herbaceous perennials; likewiſe ſome plants and trees, after obtaining a great age and bulk, totally decay, after having once flowed; ſuch as often occurs in the *agave*, or great American aloe, which in this country in particular, after fifty or an hundred years growth before they attain a flowering ſtate, they then expanding in the centre and ſhoot up rapidly, into a ſtalk of prodigious height, for flowering, which continuing in bloom two or three months, and the plants generally decay ſoon after, never ſurviving to flower again: the ſame alſo happens in the *muſa paradiſiaca*, or plantain-tree, which having been in ſome European gardens a hundred years, and after having once flowered, no art can prevent its lofty ſtem from periſhing the year after; and the like alſo often occurs in the *lavatera arborea*, or tree-mallow.

SIDEROXYLON, Iron-Wood.

It conſiſts of ſhrubby ever-green exotics of Africa, retained here in hot-houſes for variety; are adorned with oval leaves, in one ſort large, the other ſmall, and monopetalous wheel-ſhaped flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is ſmall monophyllous, five-parted at top, and permanent.—COROLLA, is monopetalous, wheel-ſhaped, and five-parted.—STAMINA, five awl-ſhaped filaments, having oblong incumbent antheræ.—PISTILLUM, a roundiſh germen, awl-ſhaped ſtyle, and ſimple obtuſe ſtigma.—PERICARPIUM, a roundiſh umbilicated unilocular berry, containing one oval unilocular nut.

There are about three ſpecies, one of which is inermous, or without ſpines, the others are ſpinous.

[1]SIDEROXYLON *Inerme.*

*Inermous, or Smooth Æthiopian Sideroxylon*] Riſes with a ſhrubby ſtem, branching irregularly ſix or eight feet high, being inermous, or without ſpines, garniſhed with large, oval, firm, ſmooth, ſhining, green leaves, and flowers at the ſides and ends of the branches.

[2]SIDEROXYLON *Spinoſum.*

*Spinous Malabar Sideroxylon.*] Riſes with a ſhrubby branching ſtem, ſeveral feet high, armed with ſpines, ſmall, oval, firm, ſmooth, perennial leaves, and flowers at the ends of the branches.

The above two plants rarely flower in England.

They being tender exotics from hot countries, muſt be kept always in pots and placed in the ſtove.

[3]SIDEROXYLON *Lycioides.*

*Lycioides, or Canada deciduous Sideroxylon.*] Hath a ſhrubby ſtem and branches, armed with

with ſpines, and garniſhed with ſpear-ſhaped, ſhining green, deciduous leaves.

The wood of theſe ſhrubs being ſo very ſolid, remarkably hard and ponderous, as to ſink in water, they obtained the appellation of Iron-wood.

They are propagated by ſeeds procured from abroad, which, of the two firſt ſorts in particular, muſt be ſowed in ſpring, in pots of rich earth, and plunged in the bark-bed; and when the ſeedlings are come up two or three inches high, pot them off ſeparately, and place them always in the ſtove.

Their propagation may alſo be tried by layers and cuttings, aſſiſted by heat.

SILENE, Viſcous Campion, &c.

The plants are moſtly hardy herbaceous annuals and perennials, ſome of which merit culture, as flowering plants, which are principally of erect growth, with ſtalks about half a yard, or two or three feet high, garniſhed with oblong, oval, and narrow ſimple leaves, and the ſtalks terminated by bunches of ſmall pentapetalous flowers.

Claſs and order, *Decandria Trigynia.*

*Characters.*] CALIX, is monophyllous, quinquedented, and permanent.—COROLLA, five plane, obtuſe, ſometimes bifid petals, with narrow ungues, and a nectarium formed of two denticles in the neck of each petal.—STAMINA, ten awl-ſhaped filaments, alternately inſerted into the ungues of the petals, having oblong antheræ. — PISTILLUM, a cylindric germen, three ſimple ſtyles, crowned by ſtigmas, reflexed contrary to the ſun.—PERICARPIUM, a cylindric trilocular capſule opening five ways at top, and many reniforme ſeeds.

There are many ſpecies, annuals, biennials, and perennials, and of which the following are the moſt noted ſorts.

[1]SILENE *Armeria.* (*Annual.*)

*Armeria, commonly called Lobel's Catch-fly.*] Riſes with erect, branchy, clammy ſtalks, half a yard high, having the upper leaves heart ſhaped, and all the branches terminated by faſtigiated bunches of flowers, of different colours in the varieties.

*Varieties.*] Common red-flowered, —— white flowered,—purple-flowered.——All of which flower in June and July.

[2]SILENE *Quinquevulnera.* (*Annual.*)

*Quinquevulnerous, Viſcous Campion, commonly called Dwarf Lychnis.*] Riſes with upright channelled ſtalks, branching numerouſly twelve or fifteen inches high, oval ſpear-ſhaped, hairy, oppoſite leaves, and all the branches terminated by ſhort ſpikes of purple flowers edged with white, having roundiſh entire petals, ſucceeded by erect fruit alternately: appearing in May, June, and July.

Both the above ſpecies are hardy annual flowers, and have been in eſtimation for adorning the borders in ſummer, being commonly ſowed in ſmall patches in the places where they are to flower.

[3]SILENE *Muſcipula.* (*Biennial.*)

*Muſcipula, or Spaniſh Viſcous Campion.*] Hath a biennial root, an upright, round ſtalk with ſwelling joints, and branching by pairs, a foot and half high; narrow ſpear-ſhaped, ſmooth leaves, ſurrounding the ſtalk in cluſters; and at the axillas, cloſe-ſitting, red-flowers, with bifid petals.

[4]SILENE *Viridiflora.* (*Biennial.*)

*Green-flowered Portugal Campion.*] Hath a biennial root, upright, taper, downy ſtalk, branching alternately a foot or more high; oval, ſpear-ſhaped, downy leaves, and the branches terminated by panicles of whitiſh-green flowers.

[5]SILENE *Nutans.* (*Perennial*)

*Nutant or Nodding Mountain Campion.*] Hath a fibrous perennial root, upright ſtalks, two feet high, ſpear-ſhaped leaves; and from the upper part of the ſtalks, nodding panicles of white flowers arranged, drooping on one ſide, having bifid petals.

[6]SILENE *Bupleuroides.* (*Perennial.*)

*Bupleuroide-leaved Perſian Campion.*] Hath a perennial root crowned with large cluſtered heads of ſpear-ſhaped acute leaves, upright ſtalks a foot and a half high; and oppoſite pedunculi, each ſuſtaining two or three white flowers with bifid petals and ſhort bractea.

[7]SILENE *Fruticoſa.* (*Perennial.*)

*Shrubby Sicilian Viſcous Campion.*] Riſes with a low ſhrubby ſtem, branching a foot or more high, having broad ſpear-ſhaped leaves, trichotomous panicles of greeniſh-white flowers.

All theſe plants flower here in ſummer from May till Auguſt in the different ſorts, each flower having five petals, and ſeveral of the ſorts produce ripe ſeeds, particularly the annuals and biennials, by which all the ſorts may be raiſed, and the perennials alſo by parting the roots, &c.

They are all hardy herbaceous plants, and for the general part have very viſcous or

clammy ſtalks, particularly juſt below the joints, to which flies often ſtick faſt, hence the name Catchfly, and Viſcous Campion, &c.

They will all proſper in any of the garden compartments, and may be employed for ornament and variety in different parts of the pleaſure-garden.

The two annual ſorts, in particular, are cultivated in many gardens as flowery plants, which being raiſed from ſeed may be ſowed in autumn or ſpring, where they are to flower: the autumnal-ſowed plants flower earlier and ſtrongeſt, though it is beſt to ſow at both ſeaſons, repeating alſo the ſowing in ſpring and early part of ſummer, in order to obtain a longer bloom, obſerving to ſow them in patches about the borders; and after the plants come up thin out the weakeſt, leaving only two or three in each patch, and they will then grow ſtrong and flower plentifully in June and July, and ripen abundance of ſeeds in autumn.

The biennial ſorts are raiſed from ſeeds ſowed in autumn or ſpring in a bed or border and raked in, and when the plants are come up an inch or two high, prick them out in nurſery-beds till autumn, then tranſplant them into the borders, &c.

The perennials may be propagated by ſlipping their heads, and parting the roots, and the ſhrubby ſort alſo by ſlips of its branches in a ſhady border.

They may alſo be raiſed from ſeeds like the biennial.

SILPHIUM, Baſtard Chryſanthemum.

The plants are principally tall-growing, herbaceous perennials for ornamenting the pleaſure-ground, riſing with annual ſtalks ſeveral feet high, adorned with divided and entire leaves, and the ſtalks crowned with compound radiated flowers.

Claſs and order. *Syngeneſia Polygamia Neceſſaria.*

*Characters.*] CALIX, is oval, ſcaly, imbricated, and permanent, having the ſcales prominent and reflexed in the middle.—— COROLLA, a compound radiated flower, conſiſting of funnel-ſhaped, barren, hermaphrodite florets in the diſc, and ſpear-ſhaped females in the radius.—STAMINA, five ſmall filaments in the hermaphrodite florets, having cylindric antheræ.—PISTILLUM, in the hermaphrodites a taper germen, long ſlender hairy ſtyle, and ſimple ſtigma; and in the females a heart-ſhaped germen, ſhort ſimple ſtyle, and two briſtly ſtigmas.—PERICARPIUM, none.—SEMEN, no ſeed in the hermaphrodite, but in the females ſingle heart-ſhaped ſeed, having a membranaceous two-horned border.

The ſpecies are,

[1]SILPHIUM *Trifoliatum.*

*Trifoliate Virginian Silphium.*] Hath a fibrated, ligneous, perennial root, upright, firm, purpliſh ſtalks, branching four or five feet high; large, oblong, rough, ſharply-ſerrated leaves, generally by threes or fours round the ſtalk; and at the ſides and ends of the branches long peduncles, each ſuſtaining one radiated yellow flower.

[2]SILPHIUM *Solidaginoides.*

*Solidaginoide Virginian Silphium.*] Hath a fibrated perennial root, upright ſtalks a yard high; ſpear-ſhaped, acute, ſerrated, oppoſite leaves on ſhort foot-ſtalks; and the ſtalks terminated by radiated yellow flowers looſely diſpoſed.

[3]SILPHIUM *Aſteriſcus.*

*Aſteriſcus, American Sylphium.*] Hath a fibrous, perennial root, upright, thick, hiſpid ſtalks three or four feet high; oblong, rough, undivided, cloſe-ſitting leaves, alternate below, but oppoſite above; and the ſtalks terminated by radiated yellow flowers.

[4]SILPHIUM *Laciniatum.*

*Laciniated American Sylphium.*] Hath a fibrous perennial root; upright, very thick, taper, ſimple ſtems, eight or nine feet high; large pinnatifid, ſinuated leaves alternately; and the ſtalks terminated by radiated yellow flowers.

All theſe four ſpecies flower here annually in July and Auguſt, the flowers are univerſally compound and radiated, each flower conſiſting of many florets in one ſcaly, imbricated, general calix, tubular florets in the diſc, and ſpear-ſhaped ones from the radius; but the ſeeds do not ripen freely in England.

They are all very hardy herbaceous perennials, durable in root, but renew their ſtalks annually in ſpring, which flowering in ſummer, decay to the root in autumn.

All the ſorts are proper ornamental furniture for large compartments in aſſemblage with other tall-growing perennials, where they will effect a good variety in ſummer.

They are all eaſily propagated by parting their roots in autumn, planting the ſlips at once where they are to remain, and they will flower the following year.

SINAPIS,

SINAPIS, Muſtard.

The plants are moſtly hardy herbaceous annuals, ſome of which merit culture as eſculent herbs, both for ſallading and for their ſeeds for making muſtard; all of which riſe with erect branchy ſtalks from two to three or four feet high, garniſhed with broad, rough, deeply-jagged leaves, and the branches terminated by ſpiked cluſters of tetrapetalous cruciforme flowers.

Claſs and order. *Tetradynamia, Siliquoſa.*

*Characters.*] CALIX, four narrow, cruciforme, deciduous leaves.—COROLLA, four roundiſh, plane cruciforme petals, and four oval nectari.—STAMINA, four long and two ſhort filaments, having erect patent antheræ. PISTILLUM, a taper germen, a ſtyle the length thereof, crowned with a headed ſtigma.—PERICARPIUM, an oblong, ſwelling, rough, bilocular, bivalvous pod, having many globoſe ſeeds.

The principal ſpecies for general culture are,

[1]SINAPIS *Alba.*

*Common White Muſtard.*] Riſes with large, rough, jagged leaves, upright, branchy, hairy-ſtalks two feet high, or more, garniſhed alſo with jagged rough leaves, and all the branches terminated by looſe ſpikes of numerous yellow flowers, ſucceeded by hiſpid pods, having long oblique beaks, and contain white ſeeds.

This is the common White Muſtard uſually cultivated in gardens as one of the ſmall ſallad-herbs, and may alſo be raiſed for its ſeed to make Muſtard.

[2]SINAPIS *Nigra.*

*Black Muſtard.*] Riſes with erect, branching ſtalks, four feet high or more, garniſhed with large, rough, jagged leaves, and the branches terminated by ſpiked cluſters of yellow flowers, ſucceeded by ſmooth pods, tetragonous at top, containing blackiſh-red ſeeds.

This is the ſort which is commonly cultivated in fields for its ſeed, of which to make the common Muſtard for general uſe.

[3]SINAPIS *Arvenſis.*

*Field Sinapis, or Durham Muſtard.*] Riſes with erect ſtalks two feet high, garniſhed with oblong, rough leaves, and the branches terminated by bunches of yellow flowers, ſucceeded by multangular, ſwelling, turgid pods, with long beaks.

The two firſt ſpecies flower in June and the ſeeds ripen in July and Auguſt, but the third flowers in May and the ſeeds ripen in June.

Theſe three ſpecies of *Sinapis* are hardy herbaceous annuals, that grow naturally in the fields in England, and moſt parts of Europe; but the ſecond and third ſort, in particular, grows abundantly among the corn, and by way-ſides in many parts of England, and are alſo cultivated in gardens and fields in large quantities for their ſeeds for Muſtard; the *Sinapis Alba*, however, is cultivated in gardens principally as a ſallad-herb: and the *Sinapis Nigra*, and the Field *Sinapis* are the chief ſorts that are cultivated for their ſeed to manufacture for Muſtard; but of the ſeed of the third ſpecies in particular is made that ſort called Durham Muſtard; however, good Muſtard may be made of all the three ſorts, all of which being ſowed in the ſpring ſoon come up, ſhoot up to ſtalks, and produce ripe ſeeds in three or four months, then totally periſh; ſo that a freſh ſupply is raiſed annually from ſeed.

The White Muſtard, however, being uſed in gardens as a ſallad-herb, is ſowed along with other ſmall ſallading at all times of the year, even ſometimes every week or oftener, in a bed or border of light earth, ſowed generally in ſhallow drills very thick, covering it very thinly with earth; and in winter, and early in ſpring, during the cold weather, is ſowed alſo in hot-beds; and the herbs are always cut for uſe whilſt in the ſeed-leaf and but a few days old; otherwiſe they will become too ſtrong and rank taſted.

But for the particular methods of raiſing this ſort as a ſallad-herb, together with other ſmall ſallading at different times of the year. See SALLAD-HERBS and SMALL SALLADING.

Obſerve, in order to ſave ſeed of this ſort for garden uſe, ſow it on an open ſpot of ground in March or April, either thinly in drills a foot aſunder, or broad-caſt all over the ſurface, and let the plants run up to ſtalk, and they will furniſh ripe ſeeds in Auguſt.

To raiſe the plants for the ſeed for Muſtard, they ſhould be ſowed in the ſpring, any time in March, in ſome open ſituation either in a kitchen-garden, or in the open fields, where large quantities are required for ſale; in either caſe, having digged or ploughed the ground, then ſow the ſeed broad-caſt all over the ſurface, and rake or harrow them in lightly, or ſow it in ſhallow drills a foot aſunder. They will ſoon come up, obſerving, that when the plants have four or more

leaves

leaves an inch or two broad, thoſe ſowed in the broad-caſt way ſhould be hoed and thinned, leaving them ten or twelve inches aſunder, and cut up all weeds, repeating it once or more if neceſſary; after this the plants will ſoon ſpread and cover the ground, and ſhoot faſt up to ſtalks for flowers and ſeed, which will ripen in July or Auguſt, and the third probably in June, when the ſtalks ſhould be cut or pulled up, and thraſhed out for uſe.

SISIMBRIUM, Water-Creſs.

Conſiſts of hardy herbaceous annuals and perennials, moſtly of the aquatic tribe, one of which is in high eſtimation as a ſallad-herb; are moſtly of ſpreading growth, garniſhed with pinnated and pinnatifid leaves, and the ſtalks terminated by ſpikes of ſmall tetrapetalous cruciforme flowers.

Claſs and order, *Tetradynamia Siliquoſa.*

*Characters.*] CALIX, four linear, ſpear-ſhaped, ſpreading, deciduous leaves.—COROLLA, four oblong, patent, cruciforme petals.—STAMINA, four long and two ſhort filaments, having ſimple antheræ.—PISTILLUM, an oblong, ſlender germen, very ſhort ſtyle, and obtuſe ſtigma.—PERICARPIUM, a long, taper, incurved, bivalvous bilocular pod, having many ſmall ſeeds.

There are more than twenty different ſpecies of this genus, but the greater part being plants of no merit are rarely cultivated: one ſort however, *Common Water-Creſs*, demands attention as a wholeſome ſallad-herb.

SISYMBRIUM *Naſturtium.*

*Naſtartium Aquaticum, or Water-Creſs.*] Hath a fibrous, ſpreading, perennial root, ſtriking deep in the mud under the water, and ſends up ſeveral branchy ſhoots, becoming hollow ſtalks, garniſhed with pinnated leaves of four or five pair of nearly heart-ſhaped lobes, and an odd one, and the branches terminated by looſe ſpikes of ſmall whitiſh flowers, in June, and the ſeeds ripen in July.

This plant is a perennial, grows abundantly in ſhallow ſtanding waters, on the margins of ſmall rivers, brooks, running ſprings, watery ditches, and moiſt meadows, almoſt every where; and being of a fine warm, agreeable, fat reliſh, is greatly eſteemed as a winter and ſpring ſallad herb, and as ſuch every one may obtain it at an eaſy rate, either by gathering it themſelves where it grows naturally, or by purchaſing it of the ſimplers, or herb-people, eſpecially about London, where great quantities are daily brought for ſale in autumn, winter, and ſpring, tied in ſmall bunches, which they retail for a penny or two-pence *per* dozen; and many people buy them conſtantly as a choice, wholeſome, palatable ſallad, to eat either alone, or mixed with other ſallad-herbs.

It is a good purifier of the blood, and is admirable againſt the ſcurvy.

This plant, however, as it grows wild in great plenty almoſt every where in watery places; is rarely cultivated in gardens, though it may be eaſily raiſed abundantly in any ditches of water, ſhallow ponds, and other moiſt places, either by tranſplanting the plants with roots from the places of their growth, or by ſeed.

Its propagation therefore may be effected both by parting the roots and by ſeed.

By parting the Roots.—In ſpring, or any time of the year, whilſt the plants are young, may eaſily ſlip off a quantity, with plenty of roots to each, which plant directly, in ſome ſhallow, watery place, as before obſerved, they will readily ſtrike into the mud, ſpread conſiderably, and will ripen ſeed and ſow themſelves, and furniſh plenty of plants for uſe.

By Seed.—Procure a quantity of the ſeed in ſummer as ſoon as ripe, in the places where the plants grow naturally, and ſow them directly in any moiſt place to remain; or get a quantity of the plants juſt as the ſeeds begin to ripen, and throw them into any ſhallow water, they will ſtrike root, ripen, and ſhed their ſeeds, which falling to the bottom will grow and furniſh plenty of young plants.

SISYRINCHIUM *Bermudiana.*

The plants are low, herbaceous, flowery perennials for the pleaſure-garden, riſing with ſword-ſhaped leaves and ſtalks half a foot high, adorned at top with ſpathaceous hexapetalous flowers.

Claſs and order, *Gynandria Triandria.*

*Characters.*] CALIX, is a ſpatha, or ſheath, formed of two compreſſed, keel-ſhaped leaves.—COROLLA, ſix oblong-oval, acute-pointed, ſpreading petals.—STAMINA, three very ſhort filaments, with bifid antheræ affixed to the ſtyle.—PISTILLUM, an oval germen under the flower, awl-ſhaped ſtyle, and trifid reflexed ſtigma.—PERICARPIUM, an oval, trigonous, trivalved, trilocular capſule, having numerous roundiſh ſeed.

There is but one ſpecies, which, however, comprehends two or three varieties, all of which are fibrous-rooted perennials.

The

The ſpecies is,

SISYRINCHIUM *Bermudiana.*

*Bermudian Siſyrinchium.*] Hath a fibrous perennial root, crowned with ſeveral ſword-ſhaped, two-edged, ſtiff leaves, five or ſix inches long; amidſt them an erect, two-edged ſtalk half a foot high, garniſhed alſo with ſword-ſhaped, amplexicaule leaves, and adorned at top with ſeveral ſpreading deep-blue flowers, having yellow bottoms.

*Variety. Virginian Siſyrinchium.*] Hath a fibrous perennial root, crowned with narrow, ſword-ſhaped leaves, but three or four inches long, and erect two-edged ſtalks the ſame height, terminated by two or three pale-blue flowers.

Both theſe varieties flower in June, and are ſucceeded by ripe ſeeds in autumn.

They may be employed as flowery plants in any of the compartments of the pleaſure-ground, placing them towards the front in aſſemblage with other low perennials, where they will cauſe an agreeable variety.

Their propagation is by parting the roots, and by ſeed.

By parting the Roots.—This may be performed in autumn, any time in September or October, when the roots may be taken entirely up, and ſlipped into ſeveral ſeparate off-ſets, but not too ſmall, planting them again directly, and they will root firmly before winter, and flower the year following.

By Seed.—Sow them in autumn, or early in ſpring in an eaſt border, in ſhallow drills, covering them half an inch deep; they will come up in April or May like graſs, keep them weeded all ſummer, and towards autumn prick out a quantity in nurſery-rows ſix inches aſunder, to ſtand till ſpring, then tranſplanted with balls, to where they are to remain.

SIUM Water-Parſneps and Skirret.

This genus is compoſed of hardy herbaceous perennials, one of which, (Skirret,) having an eſculent root, is ſometimes cultivated in kitchen-gardens, the others being plants of no merit are rarely cultivated; they riſe moſtly with winged leaves and upright annual ſtalks, terminated by umbellate cluſters of flowers.

Claſs and Order, *Pentandria Digynia.*

*Characters.*] CALIX, umbellate flowers, having the general umbel compoſed of ſeveral ſmaller plane umbels, with the general involucrum formed of many ſpear-ſhaped, reflexed leaves, and the partial ones of many ſmall narrow leaves.—COROLLA, the general umbel is uniform and compoſed of many ſmall flowers, each having five heart-ſhaped, inflexed petals.—STAMINA, five filaments with ſimple antheræ.—PISTILLUM, a ſmall germen under the flower, two reflexed ſtyles, and obtuſe ſtigmas.—PERICARPIUM, none.—SEMEN, two oval ſeeds to each floret.

There are ſeven or eight ſpecies of this genus, one of which only, an eſculent, have merit as garden-plants, ſome being wild weeds of ditches, and other moiſt places in England, &c. and ſeldom admitted into gardens.

The garden-ſort is,

SIUM *Siſarum.*

*Siſarum, or Skirret.*] Hath a perennial eatable root, compoſed of ſeveral oblong, thick, fleſhy fibres, collected into a head at top, crowned with pinnated leaves, of two or three pair of oblong folioles and an odd one, and when it ſhoots to ſeed, riſes with an upright ſtalk a foot high, having ternate leaves above, and terminated by an umbel of white flowers.

The root of this plant is eatable, of a ſweetiſh reliſh, being boiled and eaten like carrots and parſneps, and was formerly in much eſteem, but has become in diſrepute of late years; it is, however, accounted a very wholeſome root.

*Method of Propagation.*

It is propagated both by ſeed and by off-ſets of the roots.

By Seed.—In ſpring, any time in March, or beginning of April, is the ſeaſon for ſowing, chuſing an open ſituation, which being properly digged, ſow the ſeed either broad-caſt all over the ſurface and raked-in, or in ſhallow drills a foot aſunder; they will come up in a month or five weeks, and in two or three weeks after, they muſt be cleaned from weeds and thinned either by hand or hoe, leaving the plants ſix or eight inches diſtance; the plants will ſoon after cover the ground with their leaves, and the roots encreaſe in growth till the leaves decay in autumn, then they will be fit for uſe, and continue good till next ſpring, when they will ſhoot up for ſeed.

By Off-ſets of the Root.—The roots put out many ſide off-ſets, which in ſpring being ſlipped off ſeparately each with one or more buds or eyes at top; and in an open ſpot of ground plant them with a dibble in rows a foot

ſoot aſunder, with the crown of each ſlip an inch within the ground; or may plant them thin by trench planting, in ſmall trenches, as for aſparagus, placing them erect againſt the back of the trench, and cover in the mould over them the above depth; in either method the plants will ſoon come up ſtrong, and by autumn following the roots will be full grown, and encreaſed into large bunches fit to take up for uſe from October till March.

To ſave ſeeds of this plant, let a few of the large roots ſtand to ſhoot up into ſtalks, which will flower in July, and the ſeeds will ripen in autumn.

SLIPS, the propagating plants by Slips.

Great numbers of plants, both woody and herbaceous kinds, are propagated plenteouſly by Slips; and the method is very eaſy as well as very expeditiouſly performed.

It is effected in the woody kinds by ſlipping off young ſhoots from the ſides of the branches, &c. with the thumb and finger, inſtead of cutting them off with a knife, and are therefore called Slips, which in numerous ſmall, ſhrubby plants will grow; but is more commonly practiſed to the lower ligneous plants, ſuch as ſage, ſouthernwood, roſemary, rue, lavender, and moſt other low ſhrubby growths, which may with the utmoſt facility be multiplied by this method: and the beſt ſeaſon of the year for effecting the work is generally in ſpring and beginning of ſummer, though many ſorts will grow if planted at almoſt any time of the year; but the proper ſeaſon for the various plants is always hinted in their culture, under their reſpective genera.

Obſerve, in performing the work of ſlipping theſe ſorts, to chuſe the young ſhoots chiefly of but one year's growth, and in many ſorts the ſhoots of the year will grow the moſt readily even to plant the ſame ſummer they are produced, eſpecially the hard-wooded kinds, but in the more ſoft-wooded plants, the Slips will alſo often readily grow when a year or two old; being careful always to chuſe the moſt robuſt ſhoots ſituated on the outward part of the plants, from three to ſix or eight, or ten inches long, ſlipping them off cloſe to the branches; and clear off the lower leaves, then plant them two parts of three in the ground, giving occaſional ſhade and water, if in ſummer, till properly rooted; and then towards autumn tranſplant them where they are to remain.

Many ſhrubby plants growing into large bunches from the root, ſuch as roſes, ſpiræas, raſpberries, and numerous other ſorts, all of which may be ſlipped quite to the bottom into ſeparate plants, each furniſhed with roots, and may be planted either in nurſery-rows, or at once where they are to remain.

As to the ſlipping of herbaceous plants, numerous ſorts multiply by the root, &c. into large bunches, which may be ſlipped into many ſeparate plants; and it is effected by ſlipping off the encreaſed ſuckers or off-ſets of the root, and ſome ſorts by the off-ſets from the ſides of the head of the plants, and ſome few ſorts by Slips of their ſtalks or branches; but for the greater part by ſlipping the roots, as in moſt of the bulbous-rooted tribe, and innumerable fibrous-rooted kinds.

The ſlipping of the bulbous plants is performed in ſummer when their leaves decay, and the roots being then taken up, ſlip off all the ſmall off-ſets from the main bulb, and the Slips and off-ſets ſhould generally be planted again ſoon in nurſery-beds for a year or two. See BULBUS.

And as to the fibrous-rooted ſorts, the ſlipping ſhould generally be performed in the ſpring, or early part of autumn, which may be effected either by ſlipping the outſide off-ſets with roots, as the plants ſtand in the ground; or to perform it more effectually, may take the whole bunch of plants up, and ſlip them into ſeveral ſeparate parts, each Slip being furniſhed alſo with roots, planting them, if ſmall, in nurſery-rows a year, to gain ſtrength; or ſuch as are ſtrong may be planted at once where they are to remain.

Farther particulars of the method of ſlipping plants is mentioned in the culture of the different ſorts under the proper heads.

SMALL SALLAD HERBS.

Several young ſeedling-herbs of a warm nature are in eſtimation for Small Sallading to mix with the larger principal Sallad Herbs, as obſerved on a former occaſion, ſuch as lettuce, endive, and celery, in order to improve their flavour and wholeſome quality.

The ſorts therefore in general eſtimation as Small Sallad Herbs, are creſſes, muſtard, radiſh, rape, and turnep; alſo ſometimes lap-cabbage-lettuce for winter and early

ſpring uſe; all of which herbs conſidered as Small Sallading, are always in perfection as ſuch, when quite young, that is, not more than a week, or ten or twelve days old, whilſt they remain moſtly in the ſeed-leaf, being then cut up cloſe to the ground for uſe; for they being moſtly of a warm reliſh, in which conſiſts their chief excellence for winter and ſpring Sallads, if ſuffered to grow large, and come into the rough leaf, they become of a diſagreeable, ſtrong, hot taſte; but being uſed when only a few days old, conſiſting principally of the ſeed-leaves, as juſt above obſerved; they eat exceedingly tender with an agreeable warm flavour, highly reliſhing to moſt palates, which renders them eminent furniture to mix in all winter and ſpring Sallads particularly; but from June till September they are not ſo generally regarded, though many perſons are fond of them at all ſeaſons of the year, and in default of other Sallad Herbs many often uſe them alone as Sallading in the winter and ſpring months; they, however, are preferable when mixed with lettuce and the other principal Sallad Herbs. See SALLAD HERBS.

Let it be obſerved, all the above-mentioned Small Herbs belong to different genera, and that, beſides their uſes for Sallads, ſeveral of them are alſo cultivated for other uſeful purpoſes, all of which is hinted, together with their proper culture for their ſeveral uſes under their reſpective genera; but conſidered as Sallad Herbs, they require a particular culture, and we therefore judged it eligible to exhibit their culture for that purpoſe under this head, *Small Sallad Herbs*, and, as ſuch, the ſame culture ſerves for all the ſorts, they being all raiſed from ſeeds at various ſowings the year round, as directed in their culture below.

Obſerve, therefore, that for the purpoſe of Sallading they may be obtained young at all times of the year, in ſpring and ſummer in the open ground; and in winter under ſhelter of frames and glaſſes, and occaſionally in hot-beds.

*General Obſervations on their Culture.*

They are all raiſed from ſeed, which for Sallading, is ſowed at all times of the year, when they are required; in the open ground, from March till October or November, and in the winter months they will require ſhelter of frames and glaſſes, &c. and the aſſiſtance of hot-beds occaſionally, as we before noticed: and where a conſtant ſupply is required, a repetition of ſowing will be requiſite every week, or ten days, or a fortnight, according to the ſeaſon of the year and the demand for uſe, being ſowed generally in flat ſhallow drills, very thick, and only juſt covered with earth, and are alſo ſometimes ſowed all over the ſurface, eſpecially upon hot-beds.

But as they require ſomewhat different culture at different times of the year, we will exhibit it under different heads accordingly, viz. *Spring Culture*, *Summer Culture*, *Winter Culture*.

*Spring Culture.*

In the ſpring-culture of Small Sallading, it may be raiſed both in the open borders and in hot-beds occaſionally, according as it may be required, early or late, but when it is required as early as poſſible it muſt either be ſowed in hot-beds under frames and lights, &c. or in default of a hot-bed, in a warm border under glaſſes.

Firſt the early culture in Hot-beds.—You may begin to ſow in hot-beds any time in January or February, and when a conſiderable ſupply is daily required, may continue ſowing every week or fortnight in hot-beds till March, or during the cold weather. Let a moderate hot-bed of dung be made for one, two, or more garden-frames, only half a yard, or two feet depth of dung, according to the temperature of the ſeaſon, as the heat is only required to bring up the ſeeds quickly, and forward the plants about a week; place a frame thereon directly, and mould the bed all over with light rich earth, five or ſix inches thick, making the ſurface level and ſmooth; then if you would forward your Sallading as much as poſſible, you may directly ſow the ſeed, which may be effected either in drills as ſhallow as poſſible, about three inches broad, and flat at the bottom, and three inches aſunder, ſowing the ſeeds of each ſort ſeparate and very thick, ſo as almoſt to cover the ground, and only juſt cover them with earth: or, to make the moſt of the bed, may ſow the ſeed all over the ſurface, previouſly ſmoothing it lightly with the back of the ſpade, then ſow the ſeeds all over the bed, the different ſorts ſeparately, and all very thick, as juſt obſerved, and after preſſing them all even and lightly down alſo with the ſpade, cover them very thinly with earth, by ſifting over as much light mould as will only juſt cover the ſeed, as aforeſaid, and as

ſoon as the ſowing is performed in either method, put on the lights; the ſeeds will quickly germinate and will come up in two or three days or leſs, being careful at this time to give vent to the ſteam ariſing in the bed, as well as indulge the plants with plenty of free air daily, either by tilting the lights in back or front, according to the temperature of the weather, or by drawing the lights a little down, or taking them quite off occaſionally in mild days at firſt; for the hot-bed being yet new, there will be a conſiderable ſteam ariſing, and the Sallading coming up very thick, unleſs due vent is given to paſs off the ſteam and admit freſh air, they will be apt either to burn, or fog (as the gardeners term it) and mould off as faſt as they come up. Such hot-beds, however, that are not freſh made, do not require all this precaution, but in new made beds it muſt be ſtrictly obſerved till the Sallading is all fairly come up, and as long as the ſtrong ſteam continues, and the plants will be fit for uſe in a week or ten or twelve days from the time of ſowing.

Thus continue to repeat the ſowing in hot-beds every week or ten days during the cold weather; the ſame hot-bed ſometimes retaining its heat, will admit of two ſowings, by ſowing again as ſoon as the firſt crop is gathered; however to obtain a regular ſupply daily, continue to make freſh hot-beds occaſionally, ſowing and managing them as above.

Sometimes where only a ſmall quantity for family uſe may be wanted only at a particular time, as ſoon as poſſible, and that you have the convenience either of cucumber and melon hot-beds, or a hot-houſe, &c. ſome ſeed of each ſort may be ſowed in pots or boxes, and placed in the ſaid hot-beds or ſtove juſt to bring up the plants fit for uſe; which on ſome particular occaſion may be ſufficient without making a hot-bed on purpoſe.

For want of frames and lights to place over the hot-bed, may uſe hand or bell-glaſſes, or arch the bed with low hoop-arches, in order to cover with mats at night, and in bad weather.

Or in default of hot-beds in cold weather early in the ſpring, may prepare part of a warm-border, or other ſunny ſituation, for ſome garden-frames and lights, hand-glaſſes, &c. raiſing the ground ſomewhat to the ſun; and having dug it, and raked it fine, then ſow the ſeed either in ſhallow drills, as before obſerved, or all over the ſurface in the manner as directed alſo in the hot-bed culture, covering it lightly with earth, and having ſet on the ſames and glaſſes, the ſeeds will ſoon come up, and the Sallading will be ready ſome conſiderable time ſooner than in the open ground.

Their Culture in the Full-ground.—From about the middle or end of February, or beginning of March, according to the forwardneſs or mildneſs of the ſeaſon, may begin ſowing Small Sallading in the open ground, repeating the ſowings every week or ten days; the firſt ſowing being performed on a warm border, and continue ſowing in that ſituation till the beginning or middle of April, then it may be ſowed in any of the open quarters, and in which the ſowings may be repeated weekly; but according as the hot-weather approaches ſhould rather ſow in a ſomewhat ſhady ſituation.

Let the ground for each ſowing, in the different ſituations, be properly digged, and the ſurface raked ſmooth.

And as to the method of ſowing in the open ground, it is moſt commonly in ſhallow drills, which ſhould be drawn with a ſmall or middling hoe held edge-ways downward, flat, or horizontally, drawing the drill along the width of the hoe, as ſhallow as poſſible, and flat or level at bottom, and three or four inches aſunder, in which ſow the ſeed evenly all along the bottom, each ſort ſeparate, and very thick, covering them in evenly with the fineſt of the mould, not more than a quarter of an inch deep; or if the ſmaller ſeeds are but juſt covered it is ſufficient, for the ſeeds being ſowed very thick, if deeply covered with mould the plants will not be able to riſe regularly.

Obſerve in the early ſpring-ſowings in the open ground, that in cold nights and all bad weather, it is eligible to cover the ground both before and after the plants begin to riſe, with large mats, which will be better if ſupported on low hoop-arches, or ranges of pegs ſtuck in the ground, juſt high enough to ſupport the mats a little from the earth, and by aſſiſtance of this covering, occaſionally in the early ſowings, you will enſure a more effectual crop, as well as forward the Sallading ſome days.

Remark, likewiſe, of the later ſowings, that when the dry warm weather commences it is proper to give occaſional waterings.

Obſerve farther, that as Small Sallading being always ſowed extremely thick, and the plants

plants conſequently coming up very cloſe together, and the ground being ſometimes by means of wet cruſted or caked at top, ſo as they cannot readily make their way through, in which caſe it is proper to whiſk the ſurface of the earth lightly with the hand, or with a ſlender broom juſt to break and diſperſe the mould a little.

*Summer Sowings.*

Small Sallading is not in general eſteem during the hot weather in ſummer, from the middle or end of May until September.

However, ſome require it all ſummer long, and it may be ſowed in any open ſituation from May till September: obſerving, however, that during the hot dry weather, it ſhould either be ſowed in ſome ſhady borders, or ſhaded with mats in ſunny days during the greateſt heat, from about ten till four o' clock, till the ſeed come up: and the ſowings ſhould be repeated every week; but as in ſummer theſe herbs ſoon become very hot taſted, to have them perfectly young and tender, it is adviſeable to repeat the ſowings every four or five days in very hot weather.

The ſowings are to be performed in ſhallow flat drills, as obſerved in the *Spring Sowing*, in the open ground, the ſeed ſowed very thick and but lightly covered with earth, for the reaſons formerly given.

And in very dry weather give daily waterings both before and after the plants begin to appear.

*Autumn and Winter Culture.*

From September to January, February, or March, is to be underſtood for the *Autumn and Winter Culture* of Small Sallading, the firſt part of which time it may be obtained in the open ground; but as ſoon as the cold weather ſets in, it muſt be raiſed under glaſſes, and in hot-beds occaſionally.

We may continue ſowing in the open ground all September and October, alſo, often, the greater part of November in mild ſeaſons; obſerving, that until towards the middle of October we may ſow them in any open ſituation, but from the middle or latter end of October, and in November, the ſowings muſt be on warm ſouth-borders, ſtill performing the ſowings in ſhallow drills; and in cold nights beſtow a covering of mats, or hand-glaſſes, &c. repeating the ſowings every week, or ten days, or a fortnight, as occaſion requires.

But when the cold weather commences in November, &c. it is adviſeable to uſe garden-frames and lights, or hand, or bell-glaſſes, chuſing a ſpot of light, rich ground in a ſunny ſituation, ſowing the ſeeds either in drills or all over the ſurface, according to the former directions, uſing the ſhelter of the frames and glaſſes as above; and thus you may raiſe plenty of Sallading, almoſt any time in winter, in mild weather; but when froſt comes, recourſe muſt be had to hot-beds.

However, in default of hot-beds to raiſe a conſtant ſupply all winter, it may be obtained great part of that ſeaſon ſowed in the natural earth, under good frames and lights, and other occaſional covering, except juſt during the time of long, ſevere froſts, when the aid of hot-beds will be neceſſary: however, in order to raiſe them as well as poſſible during winter, without the conſtant aid of hot-beds, let ſome warm ſouth-border of light rich earth, or other warm ſituation, be prepared for one, two, or more ſhallow garden-frames, raiſing it on the north ſide ſix inches, or more, ſo as to form it ſloping to the ſun, and having ſmoothed the ſurface, ſet on the frames, ſinking the back-part thereof near a foot, that the whole ſurface of the earth may be within eight or ten inches of the glaſſes, for it is of much advantage to have the glaſſes tolerably cloſe to the earth at this ſeaſon, in order to receive the greater influence of the ſun's heat, more eſpecially when without hot-bed heat at bottom. The ſeed may here be ſowed either in ſhallow flat drills, ranging from the back to the front of the frame, three inches aſunder, as in the ſpring-ſowings, or may be ſowed all over the ſurface, patting it lightly down with the ſpade, and then juſt cover it with earth as thinly as poſſible; directly put on the lights and keep them cloſe, and the plants will ſoon come up, repeating the ſowings once a week or fortnight; and thus you may continue a conſtant ſucceſſion of young Sallading moſt part of the winter; obſerving, in very cold weather, to line the frames cloſely about with dry litter; alſo in very cold nights, cover the glaſſes with mats or litter, though in very ſevere froſty weather, recourſe muſt be had to the aſſiſtance of hot-beds, as below.

By aid of hot-beds a plentiful ſupply may be had in all weathers, making ſlender dung hot-beds for frames and glaſſes, as obſerved in the early ſpring-ſowings, performing the

ſowings alſo, as there directed, and manage the bed in the ſame manner, being careful in time of ſevere froſts to line the frame all around cloſe with dry litter, covering the glaſſes alſo every night with the ſame material.

Thus far is the whole practical method of raiſing a plentiful ſupply of Small Sallading at all ſeaſons of the year.

In gathering Small Sallading for uſe at all times of the year, let it always be uſed when quite young and in the ſeed-leaf, before they grow large and ſend forth rough leaves, more eſpecially the muſtard, radiſh, and other rough-leaved kinds; and when thus young, they may be cut up quite cloſe to the ground, ſhanks and top together, all of which will then eat very tender and palatable.

But when they become large, and the rough leaves begin to advance apace, they are unfit for Sallading, as being rank and hot to the taſte, ſo ſhould be deſtroyed.

SMILAX, Rough Bindweed.

This genus conſiſts principally of ſhrubby climbers, moſtly of the ever-green tribe for the ſhrubbery, &c. riſing with trailing and cirrhoſe-climbing ſtalks, mounting by ſupport many feet high, adorned with heart-ſhaped, oval, and lanceolate leaves, in the different ſpecies, and apetalous, dioecious flowers.

Claſs and order, *Dioecia Hexandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, having bell-ſhaped, ſix-leaved, ſpreading cups, which in the females are deciduous.—COROLLA, no petals.—STAMINA, ſix filaments with oblong antheræ in the males.——PISTILLUM, an oval germen, three very ſmall ſtyles crowned by oblong, reflexed, downy ſtigmas in the females.——PERICARPIUM, a globular, trilocular berry, having two globular ſeeds.

There are twelve or thirteen ſpecies, moſtly of a ſhrubby, climbing growth, ſome hardy, and ſome of tender nature; but it is principally ſome of the hardy kinds that are eſteemed for culture in our gardens, having long trailing ſtalks, ſome armed with prickles, others are inermous, or unarmed, and moſtly climb by means of cirrhi, or claſpers, upon the adjacent trees and buſhes, many feet high, which renders them proper furniture for thickets and wilderneſs quarters, &c. are all exotics from different foreign countries, both in Europe, Aſia, and America; and the following are the moſt noted ſpecies, conſiſting of ſeveral ſhrubby, and one herbaceous kind for hardy plantations, and ſome ſhrubby ſorts for the green-houſe, &c.

*Hardy Kinds.*

Of theſe ſorts the firſt ſeven are ſhrubby, and the eighth is an herbaceous plant, all of the climbing tribe.

[1]SMILAX *Aſpera.*

*Rough Spaniſh Smilax, or Common Rough Bindweed.*] Riſes with many long, ſlender, angular, trailing, prickly ſtalks, climbing ten or twelve feet high; heart-ſhaped, indented, prickly leaves, having nine longitudinal nerves, and ſmall bunches of white flowers at the ſides and ends of the branches, ſucceeded by round red berries.

*Variety.*] With black berries.

[2]SMILAX *Sarſaparilla.*

*Sarſaparilla, or Peruvian Rough Bindweed.*] Riſes with angular, prickly, climbing ſtalks; oval, obtuſe, trinervous, ſmooth leaves, and ſmall bunches of white flowers at the axillas, ſucceeded by red berries.

[3]SMILAX *Tamnoides.*

*Tamnoide Carolina Smilax, or Black-Briony-leaved Rough Bindweed.*] Riſes with taper, prickly, climbing ſtalks; large, oblong, heart-ſhaped, ſeptemnervous, ſmooth leaves, and at the ſides of the ſtalks looſe bunches of whitiſh flowers, ſucceeded by black berries.

[4]SMILAX *Laurifolia.*

*Bay-leaved Virginia Rough Bindweed.*] Riſes with taper, prickly, trailing, climbing ſtalks; oval-lanceolate, thick, ſtiff, ſmooth, trinervous leaves; and at the ſides of the ſtalks round bunches of flowers, ſucceeded by black berries.

[5]SMILAX *Excelſa.*

*Lofty-climbing Oriental Smilax.*] Riſes with angular prickly ſtalks, climbing to the tops of the higheſt trees; heart-ſhaped, ſmooth leaves, having nine nerves, and at the axillas, ſmall bunches of whitiſh flowers ſucceeded by red berries.

[6]SMILAX *Lanceolata.*

*Lanceolate Virginia Smilax.*] Riſes with taper inermous ſtalks; lanceolate, or ſpear-ſhaped, ſmooth leaves; and ſmall cluſters of flowers ſucceeded, by red berries.

[7]SMILAX *Rotundifolia.*

*Round-leaved Canada Smilax.*] Hath taper, prickly, climbing ſtalks; roundiſh, heart-ſhaped, acuminated, ſmooth leaves, having ſeven or five nerves; and ſmall bunches of flowers, ſucceeded by ſmall fruit.

[8]SMILAX *Herbacea.*

*Herbaceous*

*Herbaceous Virginia and Maryland Smilax.*] Hath herbaceous, angular, inermous, climbing ſtalks; oval, ſeptemnervous, ſmooth leaves; and umbellate bunches of flowers, ſucceeded by ſmall berries.

*Green-Houſe Kinds.*

They are ligneous climbers, like the others, but in winter require the ſhelter of a green-houſe.

[9]SMILAX *China.*

*China Rough Bindweed, or China Root.*] Hath a thick, fleſhy root; taper, prickly ſtalks, climbing near twenty feet high; oval, heart-ſhaped, quinquenervous, unarmed leaves; and at the axillas of the ſtalks bunches of ſmall flowers, ſucceeded by red berries.

[10]SMILAX *Pſeudo-China.*

*Pſeudo-China, or Baſtard China Root.*] Hath a large fleſhy root; taper, inermous ſtalks, garniſhed with heart-ſhaped, inermous leaves, thoſe on the branches being oblong, oval, and quinquenervous; and at the axillas bunches of ſmall flowers, ſucceeded by red berries.

All the above ten ſpecies of *Smilax* flower moſtly in June and July, which in all the ſorts are apetalous, and male and female on ſeparate plants, produced commonly in bunches from the ſides of the branches, are ſmall and make no ornamental appearance, and the female flowers are ſucceeded by berries, but they rarely ripen in England.

Theſe plants are perennial in root, and all the woody kinds are durable in ſtalk, and moſtly retain their leaves the year round.

Their roots are moſtly compoſed of many fleſhy fibres ſpreading widely on every ſide, ſending up many trailing ſtalks, which in moſt ſorts being furniſhed with cirrhi, they thereby mount upon any neighbouring ſupport.

In their native ſoil abroad they grow naturally in woods and hedges, and thrive beſt under the ſhelter, ſhade, and drip of trees and buſhes.

The hardy ſorts therefore are ſingularly adapted as furniture for thickets, groves, wilderneſs, and wood works, planting them towards the front between the trees and ſhrubs, where they will run and ſpread very agreeably; exhibiting themſelves as evergreens all the year.

And the tender ſorts being potted and placed in the green-houſe collection, allowing them ſupport to climb upon, they will effect a proper diverſity.

*Method of Propagation.*

Firſt the hardy kinds.—They are propagated by ſlipping the roots, by layers and by ſeed.

By ſlipping the Roots.——Many ſtalks riſing from the roots widely around, the outer young ones of which may be readily ſlipped off with roots to each, which being performed in autumn or ſpring, may be planted either in nurſery-rows for a year or two, or at once where they are to remain.

By Layers.—The ſtalks being layed in autumn, &c. they will be well rooted and fit for tranſplanting by autumn following.

By Seed.——This is commonly obtained from abroad by the ſeedſmen in the ſpring, which may be ſowed, ſome in pots, and plunged in an hot-bed to forward their germination, otherwiſe they are apt to remain a year or more before they grow, and ſome may be ſowed in the full ground near the ſhade of ſhrubs, &c. in a light, dry ſoil, in drills thinly, and covered about an inch and half deep, marking each row with a ſtick, becauſe they will probably not come up till next year, giving however the common nurſery care of weeding and watering the pots or beds, till the plants are come up, which ſhould have occaſional ſhelter in cold weather, and when two or three years old may be planted out, finally to remain.

Tender kinds.—Both the tender ſpecies may be propagated by layers, and by dividing the roots. Perform the laying in ſpring on the young ſhoots, which by autumn or ſpring following will be fit for potting off ſeparately: and by roots, theſe being ſlipped in March or April, and the off-ſets potted ſeparately, they will ſoon take root; managing the whole as other woody exotics of the green-houſe.

SMYRNIUM, Alexanders.

The plants are large herbaceous biennials and perennials, one of which was formerly cultivated in the kitchen-garden as a culinary herb, uſed for ſtewing, &c. they all riſe with large ternate and pinnated, many-lobed leaves from the root, and erect ſtalks, ſeveral feet high, crowned with umbels of flowers.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, umbellate flowers, having the general umbel unequal and the ſmaller ones erect, without any involucrum, and

and ſcarcely viſible cups.——COROLLA, a uniform, general umbel, compoſed of numerous florets, having each five ſpear-ſhaped petals.—STAMINA, five ſmall filaments with ſimple antheræ.—PISTILLUM, a germen under each floret, two ſtyles, having ſimple ſtigmas.—PERICARPIUM, none; a nearly globular, ſtreaked, two-parted fruit, with two moon-ſhaped ſeeds.

There are five ſpecies, four biennials, and one perennial, moſtly plants of but little merit; one ſort, however, a biennial, being formerly in eſtimation as a culinary herb, we will exhibit its deſcription and mode of culture, &c.

SMYRNIUM *Oluſatrum. (Biennial.)*

*Oluſatrum, or common Alexanders.*] Hath a largiſh, downright, white, fibrated, biennial root, ſending up ſeveral large, triternate, many-lobed leaves, and upright ſtalks, dividing and branching four or five feet high, garniſhed with ternate, ſerrated leaves, having foot-ſtalks, and all the branches terminated by large umbels of white flowers.

This plant is a biennial, and is raiſed commonly from ſeed, which riſing in ſpring with large leaves, remains till ſpring following, then ſhoots up ſtalks for ſeed, and periſhes in autumn after.

The whole plant is of a ſtrong, warm, ſomewhat aromatic nature.

It being blanched like celery is then fit for uſe as a culinary plant, and is alſo uſed for medicine without blanching, its leaves and ſeeds being uſed for that purpoſe.

It is propagated by ſeed ſowed in the ſpring in any light ſoil and open ſituation, in ſhallow drills, fifteen or eighteen inches aſunder; and when the plants are come up two or three inches high, thin them to ſix or eight inches diſtance in the rows, to give them room to ſhoot up ſtrong, when earth muſt be drawn up about them; but in ſpring following, as they will ſhoot out again vigorouſly, let ſome earth be hoed up cloſe about each plant, and in three or four weeks they will be blanched for uſe.

SOIL, ſee EARTH, COMPOST, DUNG, MANURE, &c.

SOLANUM Night-ſhade, comprehending the Love-Apple and Potatoe.

This remarkable genus furniſhes many herbaceous and ſhrubby plants for ornament and uſe, conſiſting of annuals and ſhrubby perennials for adorning the pleaſure ground, green-houſe, and ſtove collections, and eminent herbaceous culinary plants; ſome being long trailers, others are of erect growth, garniſhed with pinnated and ſimple leaves in the different ſpecies, and all the ſorts adorned with ſmall rotated, five-parted flowers, ſucceeded by roundiſh, ſoft, baccaceous fruit, of various ſhapes, ſizes, and colours, in the ſeveral ſpecies, &c. being in ſome ſorts as large as apples and eggs, in others like cherries, and in ſome as ſmall as currants; ſometimes exhibiting a ſingular and ornamental appearance, and in ſome ſorts (*Love-Apple*) is alſo in eſtimation, as eſculents for culinary purpoſes; but the moſt valuable of all the ſpecies of this genus, is that admirable eſculent, *Solanum tuberoſum*, or Potatoe, for its large, tuberous, edible root, which is obtained for uſe almoſt the year round.

Claſs and Order, *Pentandria Monogynia.*

*Characters.*] CALIX, is monophyllous, cut half-through into five acute ſegments, and is permanent.—COROLLA, is monopetalous and rotaceous, having a ſhort tube below, with a large, ſpreading, plicated limb, dividing into five ſpreading, pointed ſegments.——STAMINA, five ſmall connivent filaments, terminated by oblong, connivent antheræ.—PISTILLUM, a roundiſh germen, ſlender ſtyle longer than the ſtamina, having an obtuſe ſtigma.—PERICARPIUM, a roundiſh bilocular fruit of the berry kind, punctuated at top, having a connivent fleſhy receptacle, and is filled with many roundiſh compreſſed ſeeds.

To this genus *Solanum* is now added, the *Lycoperſicon*, or Love-Apple, the *Melongena*, or Egg-Plant, and the *Potatoe*; they being found to be all of the Night-ſhade tribe, both in the characters and quality, which, according to Linnæus, is ſuppoſed to be more or leſs poiſonous, not excepting the Potatoe, though in a very ſmall degree; and may be ſaid to be the wholſomeſt of all the ſorts of Night-ſhade, there being about thirty different ſpecies, ten or twelve of which are cultivated in the Engliſh gardens for variety and uſe; conſiſting of ſome herbaceous annuals, and one ſhrubby perennial for the pleaſure-garden, &c. a few ſhrubby exotics for the green-houſe and ſtove, and herbaceous annuals and perennials for the kitchen-garden.

*Annual Kinds for the Pleaſure-ground.*

The principal ſorts are the Love-Apple and Egg-Plant, there being many other annual ſorts of leſs note; ſome are common weeds in

in our gardens, particularly the common black-berried Night-ſhade, comprehending many varieties; however the moſt material annuals under this head are the following.

[1]SOLANUM *Lycoperſicon.*

*Lycoperſicon, or Wolf's Peach, commonly called Love-Apple, or Tomatos.*] Riſes with ſtrong, herbaceous, unarmed, procumbent ſtalks, branching numerouſly ſix or eight feet long; large, pinnated, rank-ſcented leaves, of four or five pair of cut lobes, and an odd one; and ſimple racemous cluſters of ſmall yellow flowers at the axillas, ſucceeded by large, roundiſh, compreſſed, furrowed, ſoft, red fruit.

*Varieties are*] Common large, furrowed-fruited Love-Apple.—Cherry-fruited Love-Apple, having ſmooth, round, red fruit the ſize of large cherries,—Yellow cherry-fruited,—Scentleſs leaved,—Burnet-leaved.

This ſpecies and varieties are all of large trailing growth, and flower in June, July, and Auguſt, and the fruit ripens in September and October, when they appear both ornamental, and are fit for culinary uſes, particularly the common large-fruited kind, which is in high eſtimation in ſome families for improving ſoups, alſo for ſtewing, and ſauces, &c. for which purpoſes they are highly valued by the Spaniards and Portugueſe in particular, by which people they are commonly called *Tomatos*: ſo that this ſpecies is employed both as an eſculent and ornamental plant, and in both caſes its chief merit is in the fruit.

It is an annual in this country, whatever it may be in its native ſoil, which is the hot parts of America, but is hardy enough to ſucceed here in the open air in ſummer, being previouſly raiſed in hot-beds, thence tranſplanted; and as being of very rampant trailing growth, require the ſupport of walls, pales, or ſtakes, which ſhould alſo be in a ſunny ſituation, otherwiſe the fruit will not ripen freely.

[2]SOLANUM *Æthiopicum.*

*Æthiopian hard-fruited Love-Apple.*] Riſes with erect, ſmooth, herbaceous ſtalks, dividing and branching half a yard high; garniſhed with oval repand-angular leaves, and drooping pedunculi from the ſides of the branches, each bearing one white flower, ſucceeded by round, ſtriated, firm, red fruit.

[3]SOLANUM *Melongena.*

*Melongena, or Egg-fruited Night-ſhade, commonly called Egg-plant.*] Riſes with an erect, thick, firm, herbaceous ſtalk, branching erectly two or three feet high; large, oval, oblong, entire, downy leaves; and blue flowers ſingly from the ſides of the branches, having prickly cups, ſucceeded by large, oval, egg-like, pendulous fruit of different colours in the varieties.

*Varieties are*] Common white-fruited Egg-plant, having large, white, fleſhy fruit, the ſize and ſhape of a very large egg,——purple-fruited Egg-plant,—red-fruited—yellow-fruited,—prickly-fruited, &c

This ſingular ſpecies and varieties are all of upright firm growth, branching and forming full heads, well garniſhed with fine large leaves, and flowers in June and July, and the fruit attains perfection in Auguſt and September, being all of the large egg-ſhape; but the white-fruited ſort is in moſt eſteem as a curioſity, for its very great reſemblance to a hen's or ſwan's egg, effecting a ſingular appearance as they grow on the plants; and in ſome warm countries in the ſouth of Europe they are very commonly eaten and are accounted wholeſome: in England, however, they are not at all reliſhed, ſo that the plants are cultivated only as a curioſity, and as ſuch highly merit culture in the pleaſure-garden.

Theſe plants being natives of Aſia, Africa, and the warm parts of America, require to be raiſed and forwarded in hot-beds in this country.

[4]SOLANUM *Nigrum.*

*Common Black Night-ſhade.*] Riſes with an upright herbaceous ſtalks, branching a yard, or two or three feet high, oval, angular-indented leaves; and from the ſides of the branches roundiſh nodding umbels of white flowers, ſucceeded by black, and other coloured berries in the varieties.

This common black Night-ſhade, is chiefly uſed as a medicinal plant; it grows wild in gardens, fields, and dung-hills in England, and moſt parts of the world, often becoming a troubleſome weed, ſo is rarely cultivated; it, however, comprehends ſeveral varieties which were formerly conſidered as diſtinct ſpecies, but prove to belong all to the *Solanum Nigrum*, having all oval leaves, and nodding umbels, and are ſometimes cultivated in gardens for variety.

*The different Varieties are*] Common black-berried Night-ſhade, as above,—large, upright, ſpreading, black Night-ſhade,—greeniſh-yellow berried,——red-berried,—villoſe yellow berried, with taper hairy branches

and

and angular ſomewhat hairy leaves,—Guinea black-cherry-berried, with angular dentated branches, and ſmooth entire leaves,—Virginia, upright, black berried, with angular branches, and repand ſmooth leaves,—Jew's black Night-ſhade, with prickly branches. All of which produce their flowers in nodding umbels in ſummer, ſucceeded by umbellate cluſters of berries in autumn.

All the above four ſpecies and varieties are herbaceous annuals, being moſtly but of one ſummer's duration, particularly the Love-apples and *Melongena*; but ſeveral of the varieties of the *Solanum Nigrum* will often continue all winter if potted and placed in the green-houſe: however, an annual ſupply of all the four ſpecies muſt be raiſed every ſpring from ſeed; remarking, that the firſt three ſpecies, being exotics from hot countries of Aſia, Africa, and America, require to be raiſed in hot-beds in ſpring for tranſplantation into the full air in ſummer; but the fourth ſort being hardy, moſt of its varieties may be raiſed in the open ground.

Moſt of the above annuals may be employed in the pleaſure-ground for variety, more particularly the Love-apples and Egg-plants; and the former alſo as culinary plants for their fruit, as aforeſaid; but the *Melongena*, or Egg-plant, having great ſingularity in their egg-like fruit, merit a place in every curious garden: as to the *Solanum Nigrum*, or Black Night-ſhade, the beſt ſorts may be admitted in large gardens to encreaſe the variety; and if ſome are alſo planted in pots, trained up ſtreight, and placed in the green-houſe in October, they will remain green all winter, and exhibit an agreeable variety during that ſeaſon, with their umbels of ripe fruit.

*Their Propagation and Culture.*

As to the propagation and culture of all theſe annual Night-ſhades, they are all eaſily raiſed from ſeed ſowed annually in the ſpring; the three tender kinds in hot-beds, for tranſplantation in May or June, and the hardy ſorts (*Solanum Nigrum*) in the open ground.

For the tender kinds, Love-apples, and Egg-plant, prepare a moderate hot-bed in March or April, as for other tender annuals, covered with a frame and lights, and moulded over with light rich earth ſix inches thick, or may ſow them in any hot bed already made for other plants, ſuch as cucumber beds, &c. provided there is room, ſowing the ſeeds either in the earth of the bed in ſmall drills, or in pots and plunged in the hot-bed; and when the plants come up indulge them with freſh air and occaſional waterings, in common with the other plants of the hot-bed, and thin them where they ſtand too thick, that they may have room to gather ſome ſtrength previous to their tranſplantation; or if they are pricked out upon a freſh hot-bed, it will forward them conſiderably, which is more particularly neceſſary for the Egg-plants.

Obſerve, however, of the Love-apple kinds, in particular, that towards the latter end of May, when the plants are from about four to ſix or ſeven inches high, and the ſeaſon is become tolerably warm and ſettled, plant them out finally in the full ground on ſome warm border, placing them ſingly at ſome conſiderable diſtance, on account of their large ſpreading growth; planting ſome alſo againſt a ſouth fence, &c. to have the full ſun, as well as for the advantage of training their trailing branches along regularly; for unleſs they have ſupport they will trail upon the ground, and overſpread the neighbouring plants, and not ripen their fruit; but being trained againſt ſome ſunny fence like a wall-tree, or to a treilage or ſtout ſtakes, they will ſhew themſelves to proper advantage, and ripen their fruit more early and perfect, and exhibit it more ornamentally.

But as to the *Melongenas*, they being raiſed as above in a hot-bed, it is alſo adviſeable to forward them as much as poſſible by the farther aid of one or more hot-beds, in order to run the plants up to a large growth, and exhibit themſelves and fruit in full ſize and perfection.

Therefore when thoſe ſeedlings are one or two inches high, having a freſh hot bed ready, prick out a quantity about four inches aſunder, or plant ſome in ſmall pots ſingly, and plunge them in the hot-bed, giving water and occaſional ſhade, from the ſun till they are freſh-rooted, repeating the waterings as occaſion requires, and admit a due portion of freſh air every mild day by tilting the upper end of the lights; then, when the plants have been forwarded about a month in this bed, ſome may be thinned out with balls to their roots, and placed upon another hot-bed ſix or eight inches aſunder, managing them as before, it will ſtill forward them more conſiderably to a large ſtature for flowering and fruiting in perfection; obſerving, as they advance in height to raiſe the frame by

by degrees in proportion: likewiſe in their advanced growth, and as the warm ſeaſon approaches, begin to harden them gradually to the open air, in fine days; and towards the middle or latter end of June, the plants being grown tall and ſtrong, and the ſeaſon become warm and ſettled, they ſhould be removed into the full air, finally to remain: when thoſe growing in the earth of the bed may be taken up, with balls of earth to the roots, planting them either in the borders or in pots; and thoſe already in pots may be ſhifted into larger, and placed to adorn forecourts, or any other conſpicuous compartments, where they will effect a curious variety, with their egg-ſhaped fruit, all the autumn ſeaſon.

The hardy kinds.—As to the hardy kinds, conſiſting of ſeveral varieties, *(Annuals)* all the offſpring of the *Solanum Nigrum*, or Common Black Nightſhade, are eaſily raiſed from ſeed; ſowed in the latter end of March or in April, moſtly in a bed or border of light earth, ſeparately, either broad-caſt on the ſurface, and raked in, or in ſhallow drills, thinly, not more than half an inch deep; and the plants when about three inches high, planted out about the borders and in pots: or they may be ſowed at once where they are to remain, in patches in the different compartments, and the plants afterwards thinned to one in each place; or may ſow ſome of the foreign varieties, in particular, in a hot bed, to raiſe and forward them more effectually, planting them out as above.—Thus, in either method, they will arrive to a flowering ſtate in July, and produce their umbels of berries in autumn; obſerving, if deſigned to keep any of the more curious ſorts as long as poſſible, they muſt be potted, and placed in the green-houſe, where they will remain all winter.

*Hardy Shrubby Kinds.*

There is one hardy ſhrubby ſpecies, comprehending ſome varieties; moſtly wild climbing plants of the hedges, in England and moſt parts of Europe, but are retained in many gardens for variety.

[5]SOLANUM *Dulcamara.*

*Dulcamara, Bitter-ſweet, or Climbing Woody Nightſhade.*] Riſes with long, flexuous, inermous, woody ſtalks, climbing, by ſupport, many feet high; oblong, pointed leaves, with the upper ones halbert-ſhaped; and cymoſe cluſters of ſmall blue flowers, ſucceeded by bunches of ſmall, oval, red berries.

*Varieties.*] Common blue-flowered, as above—White-flowered—Variegated white ſtriped-leaved—Gold ſtriped-leaved—African thick leaved, formerly ranged as a diſtinct ſpecies, but proves to be only a variety of the *Solanum Dulcamara.*

They all flower in June, July, and Auguſt, and the berries ripen ſoon after.

All the varieties of this ſpecies are of the climbing tribe, and durable in root and ſtem, &c. but deciduous in leaf. The common ſort grows wild in field-hedges, in moſt parts of Europe, climbing over the neighbour-plants; and is often cultivated in ſhrubberies as a climber, in aſſemblage with the variegated ſorts.—But the variegated kinds are in moſt eſteem as garden plants, for the beauty of their elegant ſtriped leaves, and are therefore much employed as climbers.

As to the African thick-leaved variety, it being tender, requires to be potted, and treated as a green-houſe plant.

All the hardy varieties, however, *i. e.* the common, and two ſtriped kinds, &c. will grow freely almoſt any where in the full ground: the common ſort, in particular, will ſucceed alſo in any cloſe place, ſo is often planted even in towns and cities; and all theſe ſorts, conſidered as climbers, are proper furniture for ſhrubberies, wilderneſs quarters, groves, and thickets, and to run over arbours; allowing them ſupport of ſtakes, or placed to climb upon buſhes, &c. Allow the variegated ſorts generally a dry and rather poor ſoil, otherwiſe they will be in danger of growing too vigorous, and become plain.—They are eaſily propagated by layers and cuttings, in autumn, winter, or ſpring, and they will all be well rooted by autumn following, and fit for tranſplantation, either in nurſery rows, or at once, where they are to remain.

*Shrubby Green-houſe Kinds.*

There are many tender ſhrubby ſorts, of the quality of green-houſe plants, ſome of which are retained in our gardens for ornament and variety; which being exotics from warm countries, muſt be kept in pots, in order for moving to ſhelter in winter.

[6]SOLANUM *Pſeudo-capſicum.*

*Baſtard Capſicum; commonly called Amomum Plinii, or Winter Cherry.*] Riſes with a ſhrubby, upright, inermous, green ſtalk, branching numerouſly and erectly all around, three or four feet high, forming a regular

head, garniſhed with narrow, ſpear-ſhaped, repandous leaves; and white flowers, in ſeſſile umbels, or ſingly from the ſides of the branches, ſucceeded by many beautiful red berries, like cherries, appearing very ornamental all winter.

*Variety* ] With yellow berries.

Both the varieties are beautiful ſhrubby plants from Madeira, flowering in June, July, and Auguſt, and the fruit ripens in autumn and winter, which in both ſorts are of the ſhape and ſize of common cherries, but not eatable; appearing very beautiful all the winter ſeaſon; effecting a pretty variety in the green-houſe collection.

[7]SOLANUM *Sodomeum.*

*Apple of Sodom, Pomum Amoris, or Shrubby African Love-Apple.*] Riſes with a ſhrubby, prickly ſtalk, branching two or three feet high, having the branches alſo armed with ſpines; ob-oval, pinnatifid-ſinuated, prickly leaves, with the ſegments obtuſe; and large blue flowers in bunches, from the ſides of the branches, having prickly calyces; ſucceeded by large, round, compreſſed, yellow fruit, the ſize of a ſmall apple, ripening in winter.

[8]SOLANUM *Indicum.*

*Indian Nightſhade.*] Riſes with a ſhrubby, prickly ſtem, branching two or three feet high, with the branches alſo armed with ſpines; wedge-ſhaped, angular, entire, ſomewhat-hairy leaves, prickly on both ſides; and longiſh bunches of blue flowers at the ſides of the branches, ſucceeded by round, golden-yellow fruit, the ſize of cherries; ripening in winter.

[9]SOLANUM *Verbaſcifolium.*

*Verbaſcum-leaved, Downy, American Nightſhade.*] Riſes with a ſhrubby, inermous ſtem, branching a yard high, or more; oval, entire, downy leaves, and compound umbels of flowers at the axillas of the branches, ſucceeded by ſmall round berries.

Theſe four tender ſhrubby ſpecies flower here in June, July, and Auguſt; and they all ripen their fruit abundantly in the end of autumn, and in winter.

They are all of ſhrubby growth, durable in root, ſtem, and branches, and retain their leaves moſt part of the year. The firſt two ſorts are the moſt noted of theſe kinds in the Engliſh gardens, but the firſt ſort moſt of all; however all the four ſorts merit culture, to increaſe the variety in the green-houſe collection, as they will form a pretty diverſity, both in their flowers and fruit, moſt part of the year, but particularly in autumn and winter, when the fruit ripens, which exhibits a very ornamental appearance.

*Their Propagation and Culture.*

The propagation of all theſe green-houſe ſorts is principally by ſeed in a hot-bed in the ſpring, and the ſeed may be obtained at the nurſeries and ſeed-ſhops.

Therefore, in March or April, prepare ſome pots of rich light earth, in which ſow the ſeed thinly, and cover it half an inch deep, and plunge the pots in any common hot-bed, under frames and lights, giving frequent refreſhments of water, and the plants will ſoon come up, when a due portion of freſh air muſt be admitted daily, together with repetitions of moderate waterings occaſionally; and when the ſeedlings are about two or three inches high, it is adviſeable to prick them out upon another hot-bed; which being framed, and earthed ſix or eight inches deep, plant the ſeedlings therein, ſix inches apart, giving water, and ſhade from the ſun, till rooted. It is alſo eligible to prick ſome out in ſmall pots ſingly, and plunge them alſo in a hot-bed; obſerving in both methods to give frequent waterings, and admit a large ſhare of freſh air every day, by tilting the lights; and as the warm weather advances, harden the plants gradually to the full air, ſo as towards the middle or end of June they may bear to be fully expoſed; at which time thoſe not potted may be taken up with balls, and planted in proper pots (twenty-fours) and the already potted plants ſhifted into larger, placing them in the ſhade for a week or fortnight; managing them afterwards as other ſhrubby exotics of the green houſe.

*Tender Shrubby Kinds for the Hot Houſe.*

Under this head is compriſed four or five tender ſhrubby exotics, from the warm parts of America and Africa, and require the aid of a ſtove to preſerve them in this country; ſo are kept in pots, and placed in that department for variety.

[10]SOLANUM *Igneum.*

*Fiery-thorned American Nightſhade.*] Riſes with a ſhrubby prickly ſtem, branching a yard or more high, cloſely armed with fiery-red thorns; ſpear-ſhaped, acuminated leaves, revolute at the baſe; and ſimple racemous cluſters of white flowers at the ſides of the branches, ſucceeded by red, cherry-like berries.

[11]So-

[11]SOLANUM *Guineenſe.*

*Guinea Nightſhade.*] Riſes with a ſhrubby, inermous ſtem, branching five or ſix feet high, having alſo ſmooth branches; oval, entire leaves, and very ſlender lateral peduncles, terminated by branches of ſmall white flowers, ſucceeded by round yellow berries.

[12]SOLANUM *Tomentoſum*

*Tomentoſe Æthiopean Nightſhade.*] Riſes with a ſhrubby, tomentoſe, prickly ſtem, branching two or three feet high, armed with aceroſe prickles; heart-ſhaped, repandous, inermous, tomentoſe, or woolly leaves; and bunches of ſmall flowers, ſucceeded by golden-yellow fruit, the ſize of gooſeberries.

This ſpecies is remarkable for its tomentoſe property, it being almoſt totally covered with down.

[13]SOLANUM *Bahamenſe.*

*Bahama Nightſhade.*] Riſes with a ſhrubby, prickly ſtem, branching ſeveral feet high; ſpear-ſhaped, obtuſe, repandous leaves, reflexed in the margin; and ſimple cluſters of blue flowers at the ſides of the branches, ſucceeded by red berries.

[14]SOLANUM *Trilobatum.*

*Trilobate Jamaica Nightſhade.*] Riſes with a ſlender, ſhrubby, prickly ſtem, branching five or ſix feet high; wedge ſhaped, moſtly trilobate ſmooth leaves, and ſome with five lobes; and ſmall white flowers ſingly, ſucceeded by ſmall fruit, the ſize of elder-berries.

All theſe tender ſhrubby *Solanums* for the ſtove collections, muſt be always kept in pots of light rich earth, and retained moſt part of the year in the ſtove, except about two or three months in the heat of ſummer; and thus they will flower annually, and ripen plenty of fruit.

They are all propagated by ſeed in a hot-bed in the ſpring; ſowing it in pots of light earth, and plunge them in the hot-bed, and when the plants are come up two or three inches high, prick them ſeparately in ſmall pots, which plunge alſo in the hot-bed or bark-bed, and manage them afterwards as other ſhrubby exotics of the ſtove.

Their propagation may alſo be tried by cuttings; planting them in pots, plunge them in the bark-bed, and cover them cloſe down with a hand-glaſs.

*Hardy, Herbaceous, Eſculent Kinds.*

Under this head is compriſed only one ſpecies, Potatoe; having already mentioned a culinary ſpecies, among the tender annual kinds, viz. *Lycoperſicon*, or Love-Apple, ſometimes cultivated as an eſculent, as well as an ornamental plant; but the moſt valuable eſculent in this genus is the *Tuberous-rooted Nightſhade*, commonly called Potatoe, comprehending ſeveral varieties, all of hardy temperature, and which, for their fine, large, eatable roots, may be ſaid to be the moſt profitable culinary eſculents in the world, as they may be obtained in great plenty the year round, and are almoſt univerſally admired by all ranks of people; and in many countries are become a principal article of food among the common people. But Linnæus, and ſome other modern botaniſts, as we formerly remarked, conſidering all the Nightſhades of the lurid tribe of plants, *i. e.* ſuch whoſe foliage, &c. aſſume a diſagreeable green colour, of a forbidding aſpect, thereby ſuppoſe the plants to be more or leſs poiſonous; not excepting the Potatoe, though in a very ſmall degree: and it is ſaid a dullneſs attends the conſtant eating of them, and ſometimes a griping, more eſpecially when any conſiderable quantity is boiled and eaten in broth or ſoups, before the juice has been previouſly boiled out in another water. However, when Potatoes are thoroughly well boiled, roaſted, or baked, they prove a very palatable and wholeſome root, either to eat alone, or as ſauce to fleſh-meat, though roaſting is probably the wholeſomeſt way of uſing them. They however are cooked in various ways, in all of which they are exceedingly profitable for the ſervice of a family.

The botaniſts admit of only one real ſpecies of the Potatoe, comprehending ſeveral varieties, as above obſerved, differing in the form, colour, and other properties of the root, and colour of the flowers.

[15]SOLANUM *Tuberoſum.*

*Tuberous-rooted Peruvian Nightſhade, commonly called Potatoe.*] Hath a tuberous root, emitting numerous fibres, productive of many large roundiſh and oblongiſh, fleſhy, edible tubers; and immediately from the root riſe herbaceous, flexuoſe, ſmooth ſtalks, ſomewhat erectly, a yard long, garniſhed with large pinnated leaves, of ſeveral pair of entire lobes; and terminated by ſubdivided peduncles, ſupporting bunches of ſmall purple, or white flowers, in the different varieties, ſucceeded by roundiſh fruit, furniſhing ripe ſeed in autumn.

It is the tubers of the root only of this plant that is eatable; the fruit, the product of the ſtalk, is never uſed.

*Varieties.*] It comprehends two principal varieties, viz.—Red-rooted Potatoe, generally producing reddiſh or purple flowers.—White-rooted Potatoe, commonly bearing white flowers.—Each of which principal varieties compriſe ſeveral intermediate ones, ſuch as—Round-red—Oblong-red—Pale-red—Rough-red—Smooth-red—Red and white—Early dwarf-red—Kidney-ſhaped white Potatoe—Round-white—Large oblong-white—Large red-ended white kidney-ſhaped—Large conglomerated American Potatoe, being generally cluſtered together conſiderably, each root or tuber attaining a prodigious large ſize, being in eſtimation principally for feeding cattle.

This ſpecies *Solanum Tuberoſum* is a native of Peru, where the natives of the country commonly call it *Batatas*, and hence it here derived the European name Potatoe.

It may be conſidered both as an annual and perennial; obſerving in the firſt caſe, that the ſame individual root is only of one year's duration; for being planted in ſpring, each root ſends out numerous off-ſets, becoming proper Potatoes by autumn following, at which time the ſaid parent roots will be almoſt totally decayed; hence it becomes an annual: but in the ſecond caſe, the off-ſets of the parent root remaining ſound till the next year, when they alſo furniſh an abundant ſupply of off-ſets, hereby the ſpecies is perpetuated in great abundance from year to year, and becomes of a perennial nature: remarking, however, that a freſh plantation muſt be performed every ſpring.

With reſpect to the properties of the different varieties of Potatoes for uſe, there is no very material difference; though the red ſorts were formerly in greateſt eſteem, and, in our opinion, are the beſt for eating; though of late years, the Potatoe cultivators about London, who raiſe prodigious quantities annually, generally prefer the oblong white ſorts, particularly a ſort they call by the cant name of Red-noſed Kidney; it being a large, oblongiſh, whitiſh Potatoe, reddiſh at one end, and is eſteemed to be both more prolific in its produce, more ſaleable in market, as well as the fineſt eating Potatoe of any; therefore they have almoſt totally neglected the culture of the fine large red Potatoes, which by many are held ſuperior to the others for richneſs of flavour. It is, however, proper to cultivate a due ſhare of the beſt ſorts of each kind, all of which are raiſed in great plenty by the roots, either planted whole, or cut into ſeveral pieces, and being planted in the ſpring, each multiplies into a large cluſter of new Potatoes, fit for uſe the following autumn or winter; though ſometimes the early ſorts will be fit to take up for uſe in June or the beginning of July, of the ſize of large walnuts; ſo continue liſting them up by degrees as they are wanted till October or November, when the main crops will be full grown; at which period of growth, and not before, they are in the higheſt perfection; and the largeſt full-grown Potatoes are conſiderably finer eating than the ſmall ones, which generally eat hard, livery, and watery, entirely devoid of that fine rich meally flavour peculiar to large full-grown Potatoes, nor are they altogether ſo wholeſome for general uſe.

*Obſervations on their general Culture.*

Potatoes may be obtained for uſe plentifully almoſt the year round; the early ſorts being planted forward in the ſpring, they often afford tolerable little Potatoes fit to take up in June or July following, as formerly obſerved, eſpecially in the rich warm grounds about London, where they generally begin taking them up for market in June, before they are a quarter grown, or as ſoon as they attain the ſize of good walnuts, and thence continue taking them up occaſionally till the general crops arrive to full growth in the latter end of October; both becauſe early Potatoes fetch an extra price, and that the ground may be cleared time enough for the reception of ſome other crops, ſuch as turneps, coleworts, cabbage, ſavoys, &c. for winter, in which there is a double advantage; ſuffering, however, the greater part of the main crops of Potatoes to remain untouched until the end of October, or beginning of November, to attain mature growth, and thereby obtain the roots in their ultimate perfection, both for eating and long keeping: for Potatoes that are taken up before they have had their full growth, conſequently prove inferior both in ſize, quality, and duration; but being permitted to continue growing till autumn, about the latter end of October, or beginning of November, as above ſaid, till the ſtalks or haulm, begin to decay, the roots will be arrived to full maturity; and being then taken out of the ground in due time, and houſed in ſome cloſe dry apartment, they will keep in good perfection for eating all winter and ſpring, until the arrival of the new crops next ſummer.

All

All the varieties of Potatoes may be cultivated with ſucceſs in any open ſituation, both in gardens and the open fields; very conſiderable quantities being now cultivated in the fields round London, and moſt other great towns, for the ſupply of markets, they proving very beneficial crops; and the main crops being cleared off in due time, the ground is often ſowed with wheat, which generally ſucceeds remarkably well immediately after Potatoes.

As to the American Cluſter-Potatoe, it generally grows to a vaſt ſize, in a conglomerated or cluſtered manner, each often weighing ſeveral pounds, and at preſent is cultivated chiefly for feeding of cattle. Its culture is the ſame as the common ſorts, only requires more room to grow.

All the ſorts delight in a moderately light dry ſoil, and open ſituation; and if enriched with dung, the greater ſucceſs may be expected.

The plants are propagated moſt commonly by the root, *i. e.* the Potatoe, either whole or cut in pieces, each forming a proper ſet or plant; and being planted in March or April, in rows, two or three feet aſunder, twelve or eighteen inches apart in the rows, and five or ſix inches deep, they come up in a month or ſix weeks after, requiring no other culture than a little hoeing to kill the weeds, and looſen the ground; and each ſet will thus multiply into a large cluſter, juſt within the ſurface of the earth, attaining full growth the ſame year, fit to dig up for uſe in autumn, continuing good till ſummer following. See their *General Method of Propagation*, &c.

As Potatoes, therefore, are the moſt profitable of all our eſculent roots, and being of eaſy culture, their cultivation merits univerſal attention for the ſervice of families of all ranks, and are now in many places cultivated to great advantage for the ſupply of the markets, where they always prove a very ſaleable commodity.

In the markets Potatoes are ſold both by weight and meaſure; but in London they are always ſold by weight, at from two or three to four or five ſhillings the hundred, of ſix ſcore: though the early ones, at firſt coming in, ſell at a much higher rate; ſometimes at the enormous price of two guineas per hundred in Covent-Garden market: they, however, quickly fall to the aſore mentioned prices; and when they come in plentifully, they being generally ſorted into three ſizes, ware, middlings, and chats; the former being the largeſt, they fetch the beſt price, and the others ſell in proportion; all of which are retailed accordingly to the conſumers at from a penny, or three farthings, to one farthing per pound.

*General Method and Seaſon of Propagation, proper Soil, &c. and Method of Planting.*

The general method of propagating Potatoes is by the root or Potatoe itſelf, being the tuberous part of the root, and the only part to plant for propagation; and which may be planted either whole or cut in pieces, as formerly mentioned, and each planted ſeparately at certain diſtances, directed below.—Potatoes may alſo be raiſed from ſeed, by way of experiment, to gain new varieties: by roots, however, is the only eligible method of propagation for general culture.

Firſt by Roots.—As we above obſerved, the propagation by roots being by planting the tubers or Potatoes themſelves, a proper quantity ſhould be procured in due time in the ſpring for planting, obſerving always to procure the fineſt moderately large roots of the reſpective varieties for ſets; though ſome uſe only the ſmall chats, for planting; but we have always found that the middlings, or full-ſized roots, generally yielded the largeſt Potatoes in return. Likewiſe obſerve, that it is of much importance to change your ſets; that is, not always continue uſing thoſe of your own crops, or of any other place conſtantly, but every two or three years at moſt procure a freſh parcel of ſome different diſtant growth, which will be found of great advantage, both in preventing a degeneracy, and in the goodneſs of the crops; remarking likewiſe, the ſets may either be planted whole, or each cut in three or four pieces, preſerving one or more eyes, or buds, to each cutting: they, however, ſhould not be cut until juſt the time for planting.

The general ſeaſon for planting Potatoes is from about the middle or latter end of February to the middle of April; remarking that the early ſorts, &c. for forward crops, may be planted in the latter end of February, and early in March, in a dry warm ſituation; but for the general crops, March, and the firſt fortnight in April is the moſt eligible planting ſeaſon; eſpecially in moiſt land, as if planted earlier, and much wet ſhould ſucceed, it might rot the ſets, more particularly if cuttings: though in caſes of neceſſity, where the

the ground is not ready, &c. Potatoes may be planted any time in April, or even in May, and will yield tolerable crops by October: however, thoſe planted towards the middle or latter end of March, and early in April, are principally to be depended on for the main crops to attain due perfection.

Obſerve, as to the proper ſituation and ſoil in which to plant Potatoes, always allow them an open expoſure, and tolerably dry ſituation; and as to ſoil, they are generally the moſt proſperous in a moderately light pliable ground; none better than a good ſandy loam, in which they commonly yield fine crops: however, chuſe any the moſt convenient moderately-light land, of a pliant free-working nature, and not wet; and the ground may either be ſuch as has been in conſtant digging or ploughing before, or in graſs-ſward; obſerving in the former caſe, that if the ground be rather poor, be ſure to beſtow a good coat of dung, to be dug or ploughed in; but if the ground is in ſward, and a freſh good ſoil, hardly any dung will be required; for the ſward being digged or ploughed in properly, it generally anſwers the purpoſe of dung the firſt year, and is commonly productive of excellent crops.

The ground may either be digged or ploughed for the reception of the plants. The digging is generally the moſt practicable for gardens, and being performed one full ſpade deep will be ſufficient; and as to the ploughing, this is commonly practiſed for large quantities in fields, being careful to plough the full depth; and, if not graſs-ground, if ploughed again croſs-ways it will be the greater advantage; or in ſtubborn land, two or three ploughings may be neceſſary to divide and break the ſoil properly, performing the firſt ploughing in autumn or beginning of winter, and croſs-ploughed in ſpring towards the time for planting; and if after the ploughing, the ſurface is rough and ſtubborn, a good harrowing will be proper for the better reception of the plants.

Then with reſpect to the method and order of planting the Potatoes, they are planted either with a dibble, or holed in with a ſpade, or drilled in with an hoe, &c. as hereafter explained, in rows two feet aſunder at leaſt, twelve or fifteen inches diſtant in each row, and five or ſix inches deep, as directed below; remarking, however, the American cluſtered Potatoe in particular ſhould generally be allowed a yard diſtance between the rows; but ſome adviſe all the ſorts to be planted at that diſtance in the field-culture, in order both to admit of horſe-hoeing frequently between the rows, to looſen the ſurface of the earth effectually, and to allow a greater ſcope for growth, and a more free admiſſion of ſun and free air, to give all the chance poſſible for improving the ſize of the Potatoes.

But as to the particular methods of planting them, the following ſix are occaſionally practiſed, &c. dibble-planting, drill-planting, holeing-in-planting, furrow-planting, trenching-in-planting, and bedding-in-planting; but the three or four former are the moſt eligible methods.

By Dibble-planting.—This may be performed either with a common large garden-dibble, blunted at the bottom, making holes therewith five or ſix inches deep, at the diſtance before mentioned, dropping one ſet in each hole as you go on, and ſtriking the earth over them; but thoſe who plant large quantities in fields, have generally a Potatoe-dibble for this purpoſe, being a large long dibble, about a yard in length, with a croſs handle at top for both hands, having the lower end thick, blunt, and ſhod with iron ſix or eight inches up, the iron being alſo obtuſe or blunted at the lower end; and about ſix inches from the bottom is fixed an iron ſhoulder, both for the convenience of a tread for uſing the feet occaſionally to thruſt it into the ground, and that by ſtriking it in always to the ſhoulder, it makes the holes all an equal depth. With this inſtrument one perſon is employed in making the holes a foot or more aſunder, whilſt another follows cloſe after, and immediately drops one Potatoe-ſet in each hole; then the ground is well raked or harrowed over to cover in all the holes properly. But in gardens, where only a few are planted for family uſe, the dibbling-in the ſets may be performed with any common garden-dibble, thick and blunt at the lower end as hinted above; and one perſon may both dibble the holes and drop the ſets as he goes on, ſtriking the earth in upon them with the dibble, and afterwards rake the ground. —See the articles DIBBLE and PLANTING.

By Drill-planting.—Drills may be formed either with a large hoe or plough, two feet aſunder, and ſix inches deep, in which drop the ſets, a foot aſunder, and cover them in with the earth equally the depth of the drill.

By

By Holeing-in-planting.—This is performed with a ſpade. A man having a light handy ſpade, and beginning at one end of the line, takes out a ſpit of earth, forms a ſmall aperture about ſix inches deep, another perſon directly following after drops a ſet in the hole, the earth of the next ſpit immediately covers it up, and ſo on to the end.

By Furrow-planting.—This is ſometimes performed in fields, in very light pliable land, and is performed by dropping the ſets in the furrow immediately after the plough, and the ploughing of the next furrow turns the earth in upon the ſets of the firſt; and in another furrow, two feet from this, drop another row of ſets, which are covered in as above; and ſo on till the whole is finiſhed.

By Trenching-in.—This is ſometimes practiſed in gardens, in light ground, by way of experiment, and is effected as they proceed in digging or trenching the ground, being trenched in the common way, each trench two ſpades wide, and one ſpade deep, placing one row of Potatoes in each trench. Beginning, therefore, at one end of the ground, open a trench the proper width and depth, as above, then paring in the top of the next trench deeply, together with ſome good dung in the bottom of the firſt, levelling it evenly; and upon which lay the Potatoe-ſets in a row along the middle a foot or more aſunder: then digging along the ſecond trench a moderate ſpade deep, turning the earth thereof into the firſt trench, over the ſets, ſix or ſeven inches deep; this done, dung the bottom of the next open trench, and proceed with the digging and planting as before; and thus continue trench and trench to the end.

By Bedding-in.—This is ſometimes done in low wettiſh land, for the ſake of raiſing the beds, and ſinking the alleys deep enough to drain off the too copious moiſture, and is thus performed. The ground is divided into four, five, or ſix-feet wide beds, with alleys two or three feet wide between bed and bed; and the beds being digged, the Potatoe-ſets may then be placed upon the ſurface in rows lengthwiſe; and then dig out the alleys a ſpade deep, caſting the earth thereof over the ſets about ſix inches thick; or the alleys may be firſt digged out to raiſe the beds, and the ſets then planted with a dibble in the common method. Thus, by either of theſe methods, in wet ground, the alleys being ſunk, and the beds raiſed, the alleys drain off the redundant moiſture, which might rot the ſets before they begin to ſprout.

But in all the above methods of planting Potatoes, thoſe of dibbling-in, drilling, and holeing-in are the moſt in practice; and about London, the dibbling them in being the moſt expeditious, is the moſt commonly practiſed.

*Culture of the Plants.*

The Potatoes being however planted in either of the above methods, it now remains to ſpeak of their future management; obſerving, therefore, they are to remain in the ſame place to grow to perfection; and as to culture, when the plants come up, and weeds begin to over-run the ground, they require only two or three hoeings to kill the weeds, and looſen the ſurface of the ſoil; the Potatoes generally coming up in about a month or five or ſix weeks after planting, being accompanied by numerous weeds, which ſhould be hoed down in due time, before they grow large and overſpread the ſurface, or over-top the plants; performing the hoeings generally in dry weather by broad-hoeing, or in fields by horſe-hoeing, for the greater expedition; repeating the hoeings according as the future growth of weeds ſhall render it neceſſary, as well as to ſtir and looſen the ſurface of the ground about and between the plants, which will alſo prove very beneficial culture in improving thair general growth. After, however, two good hoeings, the plants will generally be advanced ſufficiently out of the reach of weeds, and become ſo ſpreading as to prevent their future progreſs, when no farther care will be required till the Potatoes are arrived to perfection. In hoeing Potatoes, many take the pains to hoe up a ridge of earth cloſe to each ſide of every row of plants in the firſt or ſecond hoeing, to ſtrengthen their growth more effectually, and render them more prolific; as the bottom of the ſtalks ſo landed up, generally emitting roots in the earth that become productive of Potatoes the ſame as the general roots.—Thus far is the principal culture of Potatoes, they hardly ever requiring any farther care after June and July; but the crops, however, continue growing till autumn, and the main crops in particular, which you deſign ſhall ſtand to have their full growth, will continue growing till October, or till the haulm begins to decay in November, when the Potatoes being full grown, they ſhould be then wholly

wholly taken up before they are attacked by froſt, and depoſited in ſome dry apartment for keeping: remarking, however, as we before obſerved, that new Potatoes being by many required as forward in the ſeaſon as poſſible; and ſometimes the early ſorts, growing in warm rich land, afford young Potatoes in June as big as walnuts, or little apples, in which caſe may begin to dig up ſome for preſent uſe; though only a few ſhould be taken up at a time at this early ſeaſon, juſt by way of rarity, not more than can be uſed in a day or two; for, being not a quarter grown, they will not keep long out of the ground; if even but a few days, they will neither boil, bake, or eat well; but may continue thus taking up a few at a time occaſionally, ſo as to have a conſtant ſupply from June or July, till the perfection of the general crops in October and November.

*Method of digging them up, and houſing them for Winter and Spring Uſe.*

As to the method of digging up the Potatoes for uſe, it is moſt commonly performed in gardens with a three-tined fork; and ſometimes in fields they are ploughed up for the ſake of making quicker diſpatch for conſiderable quantities; but the forking them up, however, makes the cleaneſt work; and there are Potatoe-forks for the purpoſe, being made with flat tines, blunted at the point, and fixed upon a ſpade-handle. Moſt country ſmiths know how to make them; and are ſold at the iron-mongers, and at many of the nurſeries.

Previous to the digging up the Potatoes, the haulm ſhould be cleared away for ſome conſiderable ſpace cloſe to the ground, turning it off in heaps, to clear the ſurface, for the greater convenience and expedition in digging, &c. then, if intended to fork them up, proceed by firſt opening a trench along one end of the ground one ſpade wide and deep, and then go on with the digging up the Potatoes the ſame depth, having large baſkets, &c. placed, in which to throw them as they are digged up, being careful to dig all the ground regularly along ſpit and ſpit, the bottom part of the haulm remaining to each root will be ſome direction for placing the fork, turning the ſpits clean up before you into the open trench, and pick the Potatoes of each plant clean out, great and ſmall, as you go on, and put them in the baſkets. As you advance with the digging, continue clearing off the haulm upon the dug ground in heaps, which may afterwards be burned to ſerve as manure, and thus proceed till the whole is digged up; taking the opportunity, whilſt dry, to houſe thoſe directly that are intended for long keeping.

The taking up Potatoes by the plough is performed by ploughing the ground in the common method, which turns up the Potatoes very expeditiouſly to the top, ſeveral hands following immediately after to pick them clean out.

Immediately after the Potatoes are taken up, pick out all the cut and bruiſed ones; likewiſe may ſort out the ſmall chats from the large ware, and then let the main crops for keeping be houſed, when they are perfectly dry, in ſome dry cloſe place, well defended from the free air, wet, and froſt, in which the Potatoes may be depoſited in a large heap, if brought in quite dry; obſerving, that if a ſufficient quantity of dry light earth, or ſand, is ſtrewed between them from time to time, as they are houſed, it will prove advantageous in keeping them in greater perfection, covering the whole, however, at laſt with a good thickneſs of dry ſtraw, and keep the apartment cloſe ſhut; for the more the external air is excluded, the better they will keep.

Thus the main crops of Potatoes being taken up and houſed, they will remain ſound all winter and ſpring, till the arrival of new ones next ſummer, as we before remarked, provided they are well defended, as above, from wet and froſt.

It is however to be remarked, that at the approach of ſpring, towards March and April, many of the Potatoes will vegetate and ſprout forth in the houſe, ſo ſhould be turned over occaſionally, and ſtill continue a thick covering of ſtraw, to exclude the external air as much as poſſible, and they will keep till June.

*Raiſing them from Seed.*

By Seed.—This is very rarely practiſed, becauſe their great encreaſe by roots render it unneceſſary; beſides, the propagation by roots is conſiderably the moſt expeditious and effectual method: ſo that raiſing Potatoes from ſeed is only ſometimes practiſed by way of experiment, and to try to gain new varieties. However, when this is intended, let ſome of the firſt flowering-plants be marked for ſeed, which gather in autumn when full ripe, and in March or April following ſow it in ſome light

light ſoil, in an open ſituation, in ſhallow drills, a foot aſunder; and when the plants come up, keep them clear from weeds till autumn, when, about the end of October or November, take up the roots, ſelect the fineſt and largeſt, which preſerve in ſand till ſpring, then plant them in the common way, and by autumn following they will have made proper encreaſe, and attain full perfection; and you will then judge of their properties.

SOLIDAGO, Golden-Rod. (*Virga Aurea*)

It comprizes many herbaceous flowery perennials, of upright growth, for adorning the pleaſure ground; riſing with numerous erect ſtalks, from one to ſeveral feet high, garniſhed moſtly with narrow, ſpear-ſhaped, and oval leaves, and the top terminated by numerous ſpikes of ſmall, compound, radiated, golden-yellow flowers.

Claſs and order. *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, a compound radiated flower, having an oblong imbricated cup, compoſed of ſeveral narrow connivent ſcales.—COROLLA, is compound and radiated, having numerous funnel-ſhaped, quinquedented, hermophradite florets in the diſc, and tongue-ſhaped, tridented, female florets in the radius.—STAMINA, five ſhort hair-like filaments, with cylindric antheræ.—PISTILLUM, an oblong germen, filiforme ſtyle, crowned with a bifid ſtigma, and in the females two revolute ſtigmas.—PERICARPIUM, none.—SEMEN, a ſingle oblong ſeed in each floret.

The ſpecies of Golden-Rod were formerly greatly extended, but now reduced by Linnæus to twelve ſpecies, comprehending numerous varieties, one of which is a native of England and moſt parts of Europe, and moſt of the others are from North America; but all the ſorts are very hardy, and retained in our gardens as flowering-plants.

They are all fibrous-rooted perennials, that renew their ſtalks annually in ſpring.

The ſpecies are,

[1]SOLIDAGO *Virga Aurea.*

*Virga Aurea, or Common Golden Rod.*] Riſes with ſeveral angular, ſlender, almoſt flexuoſe ſtems, from one to two feet high, garniſhed with narrow ſpear-ſhaped leaves, and divide upward into paniculated, erect, cluſtered ſpikes of golden-yellow flowers, in Auguſt and September.

*Varieties.*] Talleſt Purple-ſtalked,—Broad ſawed-leaved,—Narrow ſlightly-ſawed leaved,—Low-ſtalked, &c.—Each of which was formerly ranged as a diſtinct ſpecies, but prove to be varieties only of the common *Virga Aurea.*

This ſpecies and varieties grow naturally in many parts of England, &c.

[2]SOLIDAGO *Canadenſis.*

*Canada Rough-leaved Golden Rod.*] Riſes with ſeveral round ſmooth ſtems, two feet high; narrow, rough, trinervous, ſlightly-ſerrated leaves, and terminated by corymbous panicles, with recurved ſpikes of adſcendent yellow flowers, appearing in July and Auguſt.

[3]SOLIDAGO *Altiſſima.*

*Talleſt, Late-blowing, American Golden Rod.*] Riſes with numerous round ſmooth ſtems, four or five feet high; ſpear-ſhaped, ſawed, enervous, or unveined leaves, and terminated at top by large corymbous panicles, with recurved ſpikes of adſcendent yellow flowers, in September and October.

*Varieties.*] There are many varieties of this ſpecies, differing ſomewhat from one another, but diſtinguiſhing themſelves ſpecifically, as this ſort, by their talliſh growth, enervous or unveined leaves, and large corymbous-paniculated recurved cluſters of flowers, as above, flowering late in autumn.

[4]SOLIDAGO *Latifolia.*

*Broad-leaved Canada Golden Rod.*] Riſes with erect angular ſtalks, two or three feet high; broad, oval, ſharp-pointed, ſawed leaves, and lateral ſingle ſpikes of yellow flowers, appearing in September.

[5]SOLIDAGO *Flexicaulis.*

*Flexicaulous Canada Golden Rod, with a Fig-wort Leaf.*] Riſes with a ſlender flexuoſe ſtalk, two feet high; oval, ſharp-pointed, ſerrated leaves, lateral ſingle ſpikes of pale-yellow flowers, in September.

[6]SOLIDAGO *Mexicana.*

*Mexican Golden Rod.*] Riſes with oblique brown ſtalks, a foot and half high; ſpear-ſhaped entire leaves, and erect, branching, leafy peduncles, bearing yellow flowers, in Auguſt and September.

[7]SOLIDAGO *Cæſia.*

*Smooth Maryland Golden Rod.*] Riſes with naked ſmooth ſtems, a foot and half high; garniſhed with narrow, ſpear-ſhaped, acute-pointed leaves, and terminated by corymbous panicles, with thick upper ſpikes of yellow flowers, appearing in September.

[8]SOLIDAGO *Lateriflora.*

*Lateral-flowered American Golden Rod.*] Riſes with ſmall ſtalks a foot and half high; narrow, unſerrated, pointed leaves, and the ſtalks branching laterally below, almoſt from bottom to top, in floriferous ſpikes, ſhortening, and terminating upwards, in corymbous panicles, with recurved cluſters of yellow flowers, in September.

[9]SOLIDAGO *Rigida.*

*Rigid or Stiff-leaved, Penſylvania Golden Rod.*] Riſes with many upright ſtalks, two feet high, branching alternately; oval, ſtiff, rough, cauline leaves, and the ſtalks and branches terminated by a corymbus of yellow flowers, in September.

[10]SOLIDAGO *Noveboracenſis.*

*New York Golden Rod.*] Hath oval, oblong, radical leaves, having foot-ſtalks, branching naked ſtalks, near two feet high, garniſhed with very ſmall leaves, and terminated by panicles of bright-yellow flowers, in September.

[11]SOLIDAGO *Minuta.*

*Leaſt Pyrenean Golden Rod.*] Riſes with ſmall ſingle ſtalks, only about a foot high, ſpear-ſhaped entire leaves, and the pedunculi riſing at the axillas, each ſupporting but one yellow flower, appearing in Auguſt.

[11]SOLIDAGO *Sempervirens.*

*Sempervirent, Fleſhy-leaved, New York, Golden Rod.*] Riſes with ſeveral upright reddiſh ſtalks, five or ſix feet high; ſpear-ſhaped, almoſt fleſhy, ſmooth leaves, with roughiſh margins, and the ſtalks terminated by large corymbous panicles of bright-yellow flowers, appearing in October, and great part of the winter, in mild ſeaſons.

All theſe twelve ſpecies of *Solidago* are very hardy fibrous-rooted perennials, of great duration in root, but moſtly annual in ſtalk, which riſing in ſpring, many from each root, arrive to a flowering ſtate in autumn; all the ſtalks adorned upward with long ſpikes of numerous ſmall flowers, exhibiting a very conſpicuous bloom a month or ſix weeks, and totally decay to the root in winter.

They are ſo hardy as to proſper in any common ſoil and ſituation, with but very little trouble in their culture.

Conſidered, therefore, as garden furniture, they are proper autumnal ornaments for almoſt every compartment of the pleaſure ground, and ſhould be introduced in aſſemblage in all large borders, ſhrubberies, wilderneſs quarters, and the borders of wood-walks, &c. where, being judiciouſly diſtributed, at eligible diſtances, they will effect a grand autumnal bloom for three or four months, in the different ſorts, as each root generally ſends up numerous ſtems cloſe together, often forming a large buſh, adorned above with numerous long panicles of golden-yellow flowers, which, though ſeparately ſmall, they being numerous and cloſely placed in each ſpike, are remarkably conſpicuous and ornamental, particularly all the foreign kinds.

The flowers are univerſally compound and radiated, compoſed each of numerous hermaphrodite and female florets, as expreſſed in the *Characters.*

Moſt of theſe plants increaſe exceedingly by the roots, a ſmall ſlip of which often multiplies, in one ſeaſon, into a large bunch; and ſeveral of the ſorts being apt to ſpread conſiderably, require to be ſlipped, or cut in all round every year or two, to keep them within proper bounds.

They ſhould, therefore, be always planted at ſome conſiderable diſtance from one another, and not too near ſmall plants.

*Method of Propagation and Culture.*

The propagation of all the ſorts is effected with great facility, by ſlipping or parting the roots in autumn and winter, ſoon after their ſtalks decay, or early in ſpring, before they begin to ſhoot; not ſlip them too ſmall, and may be planted at once where they are deſigned to flower, and will all blow in good perfection the following ſummer and autumn.

All the culture they require is, to have the decayed ſtems cut down every winter; and when the roots have encreaſed conſiderably ſpreading, ſhould be ſlipped or cut in all around, as before obſerved.

SORBUS. Sorb, or Service-tree.

This genus is compoſed of noted deciduous trees, of middling ſtature, principally for ornamental plantations; growing from twenty to thirty or forty feet high, or more, adorned with beautiful pinnated leaves of many pair of folioles, and pentapetalous flowers in umbellate cluſters, towards the ends of the branches, ſucceeded by large bunches of red berries.

Claſs and order, *Icoſandria Tryginia.*

*Characters.*] CALIX, is monophyllous, concave-ſpreading, quinquedented, and permanent.—COROLLA, five roundiſh concave petals, inſerted into the calix.—STAMINA, about

about twenty awl-ſhaped filaments, having roundiſh antheræ.—PISTILLUM, a germen under the receptacle, three ſlender ſtyles, and capitated ſtigmas.—PERICARPIUM, a roundiſh, ſoft, umbilicated berry, containing three oblong cartilaginous ſeeds.

There are only three ſpecies in this genus; all three hardy deciduous trees; the firſt of which is a native of England, &c. the others are exotics from the continent of Europe and other foreign parts; the two firſt ſorts, in particular, are common in moſt of the nurſeries and eminent plantations.

[1]SORBUS *Aucuparia.*

*Bird's Service, commonly called Wild Service-tree, or Mountain Aſh; alſo, ſometimes, Quicken Tree, Quick Beam, or Roan Tree.*] Riſes with a ſtraight upright ſtem, and regular branching head, twenty or thirty feet high, or more, covered with a ſmooth greyiſh-brown bark; pinnated leaves of eight or ten pair of long, narrow, ſerrated folioles, and an odd one; ſmooth on both ſides, and large umbellate cluſters of white flowers at the ſides and ends of the branches, ſucceeded by cluſters of fine red berries, ripe in autumn and winter.

*Variety.*] Yellow-ſtriped leaved.

This ſpecies grow wild in many parts of this iſland, on mountainous places, woods, and hedge-rows, often arriving to the growth of timber, and is admitted in moſt ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit; the latter, in particular, being produced in numerous large red bunches all over the tree, exhibit a fine appearance in autumn and winter, till devoured by the birds, eſpecially the blackbird and thruſh, which are ſo allured by theſe fruit, as to flock from all parts and feed on them voraciouſly, but are not fit for domeſtic or houſhold uſe.

[2]SORBUS *Domeſtica.*

*Houſhold, or cultivated Service-Tree, with eatable fruit.*] Grows with an upright ſtem, branching thirty or forty feet high, or more, having a browniſh bark, and the young ſhoots in ſummer covered with a mealy down; pinnated leaves of eight or ten pair of broadiſh deeply-ſerrated lobes and an odd one, downy underneath, and large umbellate cluſters of white flowers at the ſides and ends of the branches, ſucceeded by bunches of large, fleſhy, edible red fruit, of various ſhapes and ſizes in the varieties.

*Varieties of the fruit are*] With Apple-ſhaped fruit—Pear-ſhaped fruit—Oval-fruited—With turbinated fruit—Compreſſed-fruited, &c.—all of which ripen in autumn; generally two, three, or four on a bunch, being ſometimes as big as little apples and pears, but are rarely palatable till they begin to aſſume a ſtate of corruption.

This tree is a native of the ſouthern warm parts of Europe, where its fruit is in high eſteem to ſerve up in deſerts, and is cultivated here, in many of our gardens, both as a fruit-tree, and to diverſify hardy plantations.

[3]SORBUS *Hybrida.*

*Hybridaceous, or Mongrel Service-Tree, of Gothland*—ſuppoſed a mongrel between the *Sorbus Aucuparia* and *Cratægus Aria.*] Grows twenty or thirty feet high; half-pinnated leaves, very downy underneath, and cluſters of white flowers, ſucceeded by bunches of roundiſh red berries in autumn.

Theſe three trees are all of the deciduous tribe, and of hardy temperature, growing freely in any of our open plantations in any common ſoil and ſituation; their foliation and flowering is generally pretty forward, commonly expanding their leaves in April, being all of the beautiful, pinnated, many-lobed kind; and the flowers appear in May and June, compoſed each of five ſmall petals, but many growing together in cluſters are conſpicuous enough; ſucceeded by baccaceous fruit, ripening in Auguſt, September, and October, often remaining on the trees after the fall of the leaf, particularly the *Sorbus Aucuparia*, which often retains its fruit all winter, or till devoured by the birds, as before remarked.

As to the merit of theſe trees in gardening, they all demand culture in every eminent ſhrubbery and other hardy plantations; being introduced as ſtandards, they will effect a fine variety in aſſemblage, with their elegant pinnated leaves and cluſters of flowers and fruit: the Wild Service, particularly, ſhould be plenteouſly interſperſed in all extenſive ſhrubberies, for the ſingularity of their numerous cluſters of berries in autumn and winter, which alſo prove food to encourage plenty of ſinging birds in the plantations.

But the *Sorbus Aucuparia* may alſo be introduced as a foreſt tree in timber plantations, being moſtly all heart is valued for many purpoſes.

And ſome of the *Sorbus Domeſtica* may alſo be employed as fruit-trees in the garden and orchard; ſome being trained as ſtandards, others as dwarfs, and againſt walls and in eſpaliers for variety, training them, nearly as directed for pears and apples.

They are raiſed in all the public nurſeries for ſale, particularly the firſt two ſorts.

*Method of Propagation, &c.*

They are all eaſily propagated in abundance, by ſeed, in the open ground, alſo by layers, though the ſeedlings generally make the handſomeſt plants.

By Seed.—The berries or ſeeds ripen abundantly in autumn, which is the proper time for ſowing them, being careful to have them perfectly ripened, gathering them in due time before devoured by the birds, and prepare to ſow them as ſoon after they are gathered as poſſible. For their reception, dig a ſpot of lightiſh ground in the nurſery, and divide it into four-feet-wide beds, in which ſow the berries, either in drills an inch deep, or bed them in, by raking the earth from off the bed near that depth; then ſowing the ſeed all over the ſurface, cover them all an equal depth, with the earth drawn off, as above, for that purpoſe: ſome of them will probably riſe the following ſpring, they, however, frequently remain till the ſecond ſpring before they come up; obſerving, in either caſe, that, in ſpring following, when the ſeedlings are a year old, they ſhould be planted out in nurſery rows, to remain till they acquire a proper ſize for final tranſplantation.

Sometimes, in order to forward the germination of theſe ſeeds, particularly the *Sorbus Domeſtica*, we ſow them in large pots, which being ſheltered under a frame in winter, and in ſpring plunged in a hot-bed, will bring up the plants the ſame year fit for tranſplantation in nurſery-rows the following autumn.

By Layers.—Having ſome of the trees, while young, cut down near the ground, it will force out lower ſhoots, which being layed, in the common way, in autumn and ſpring, they will readily emit roots, and be fit for tranſplantation in nurſery-rows in one year. This is alſo a certain method to continue any particular variety.

But the cultivated Service in particular, when deſigned to raiſe a quantity of fruit-trees for their fruit, they ſhould generally be propagated by graſting or budding the choicer-fruited kinds upon ſtocks, of any of the ſorts of *Sorbus*, raiſed from ſeeds or layers as above; they will alſo take upon pear-ſtocks.

SOUP HERBS.

Many ſorts of herbaceous vegetables, of the culinary tribe, are in great eſtimation for the improvement of ſoups, &c. a liſt of which, collected under this head, will ſerve to aſſiſt the memory in furniſhing the garden with the proper ſorts; remarking, that under the denomination of Soup Herbs, may alſo be underſtood all the ſorts of Pot-herbs uſed occaſionally in ſoups and broths, &c.

In ſome families a great variety of Soup or Pot-herbs are occaſionally required, and in others a few only of the common ſorts are uſed, ſo that every kitchen-garden ought to be furniſhed accordingly with the proper ſorts.

The following is, therefore, a liſt of the principal ſorts occaſionally uſed as Soup-herbs, &c. ſeveral of which, however, are alſo employed in various other culinary uſes, ſallads, &c. as well as for ſoups. Celery—Endive—Leeks—Lettuce—Spinach—Green and White Beet—Chard Beet—Orach—Borage—Bugloſs—Chervil—Sorrel—Parſley—Coriander—Pot-Marigold—Thyme—Winter Savory—Summer Savory—Pot or Winter Marjoram—Sweet Marjoram—Spear-Mint—Baſil—Love-Apple, or Tomatoes.

In all of which, except the Marigold and Love-Apple, the leaves are the only uſeful parts; but in the Marigold the flowers are the only part uſed, and in Love-Apple the fruit; remarking, likewiſe, that all the ſorts, but the laſt two of the liſt, (Baſil and Love-Apple) are of a hardy temperature, and may be eaſily raiſed in the natural ground; and the greater part are biennials and annuals, that require to be annually raiſed from ſeed; but the Thyme, Winter Savory, Pot or Winter Marjoram, Sorrel, and Mint, are perennials of many years duration, being raiſed ſome both by ſeeds and ſlips, others principally by ſlips; and the Baſil and Love-Apple, being tender annuals, require to be raiſed from ſeed in a hot-bed. See the culture of all the ſorts under their reſpective genera.

But the moſt prevailing Soup or Pot-herbs, of the above liſt, for general uſe are, Celery, Endive, Leeks, Spinach, Beet, Parſley, Chervil, Thyme, Marjoram, Savory, and Spear-Mint.

However, the particular merit of the different ſorts, together with the proper cul-

ture,

ure, is fully exhibited, each under its proper head.

## SOWING OF SEEDS.

Different methods of ſowing Seeds are practiſed occaſionally, as different ſorts require, and according to different practitioners; ſuch as broad-caſt ſowing and raking-in, —drill-ſowing,—bedding-in-ſowing, &c.

Broad-cast Sowing, &c.—This is the moſt common and expeditious method of ſowing in practice, particularly in the kitchen-garden, both for crops to remain, and for tranſplantation, and is performed by ſowing the Seed with a ſpreading caſt evenly all over the ſurface of the ground, either in one continued plat, or divided into beds, which is immediately raked with a large rake to bury all the ſeeds a due depth in the earth, ſome requiring to be raked in as light as poſſible, others half an inch or an inch or more deep, according to their ſize, &c.

In preparing for this method of ſowing, the ground is previouſly digged in the common way, making the ſurface level with the ſpade as you go on; no occaſion, however, to break the ſurface very fine, nor rake it, only forming it even with the ſpade, as juſt obſerved, and leave it a little roughiſh, more or leſs, in proportion to the ſize of the Seeds, that they may be more effectually buried a proper depth for germination; obſerving, for the general part, that the ground ſhould be ſowed whilſt freſh ſtirred, before the ſurface is rendered either too dry and hard by the ſun and wind, or made wet by rain; but when it is ſo moderately dry as not to clog to the feet or rake, and that it will readily fall under the rake in raking in the Seed.

All Sowing ſhould generally be performed in dry weather, more particularly all early ſowing in winter and ſpring; but in hot weather, in ſummer and autumn, it may often be eligible to take advantage of ſowing immediately after a ſhower or moderate rain.

After, however, having digged the ground as above, the Seeds are then to be ſowed broad-caſt, all over the ſurface, either in one continued plat, and raked in as before remarked; or the ground may be previouſly ſtepped out into four or five feet wide beds, with ſmall alleys between bed and bed, then ſowing the ſeed on each bed ſeparately, or may firſt ſow the ground broad-caſt, as above, and afterwards mark it out in beds, as aforeſaid. The laying out the ground in beds may, in ſome caſes, be the moſt eligible way; ſuch for example, if wet ground that cannot bear treading, we can ſtand in the alleys both to ſow the Seed and rake it in, without trampling the beds; and when weeding and watering becomes neceſſary, can alſo ſtand in the alleys to perform thoſe works; likewiſe to cull and gather the produce, or tranſplant where neceſſary; and that no ground may be loſt, we may in ſome caſes have ſucceeding crops coming forward in the alleys; however, in kitchen-gardens, where ground is ſcarce, or that it is of importance to make the moſt of every inch of ground, as well as uſe the moſt expeditious method of ſowing poſſible; the broad-caſt ſowing all over the ſurface, in one continued plat, as above obſerved, may be the more eligible practice, eſpecially in large grounds, as is the method of moſt of the kitchen-gardeners about London, for the main crops of carrots, parſneps, turneps, onions, leeks, Spaniſh lettuce, radiſhes, &c.

As to the method of ſowing the Seed in the Broad-caſt way, it is effected occaſionally both with an open and locked hand.

In the former caſe (ſowing open-handed) it is performed by delivering the Seeds with an open hand, and broad-ſpreading caſt, as practiſed in ſowing corn in the open fields, previouſly ſtepping out the ground in breaks, or certain widths, as a guide to ſow with the greater regularity; ſo proceeding with the ſowing along each ſpace with a regular ſtep and caſt, giving the hand a proper ſweeping cant forward, fully expanded at the delivery of the Seeds, making them ſpread abroad evenly in every part; and thus proceed up one ſpace and down another till finiſhed; which method of Broad-caſt ſowing is practiſed in large kitchen grounds in ſowing any conſiderable ſpace in one continued plat, as obſerved above.

But in the other caſe, (ſowing cloſe-handed,) that in narrow beds, when we intend ſowing them bed and bed ſeparately, or narrow borders, and other ſmall plats of ground, we commonly ſow or deliver the Seeds with a locked or cloſe hand, diſcharging them from between the fore-finger and thumb, opening or pinching the thumb more or leſs, according to the ſize and nature of the Seeds, and thickneſs they require to be ſowed, giving the hand a ſort of jerking turn, or cant forward at the delivery, to cauſe the ſeeds to ſpread regularly.

As ſoon as the ſeeds are ſowed in either of the above methods of ſowing, let them be directly

directly raked in before the ſurface of the ground is rendered either too dry by the ſun and wind, or made wet by rain if likely to happen; obſerve as below.

But previous to the raking in the Seed ſowed on the ſurface, as above, that if the ground is tolerably light and dry, and a dry ſeaſon, it is of importance immediately after ſowing to tread them in evenly by treading the ground all over regularly with the feet, it being more particularly neceſſary in light looſe ground in the Broad-caſt Sowing all over the ſurface, in one continued plat, which not only ſettles the Seeds, ſo as to be more effectually buried all an eligible regular depth in the raking, but alſo ſettles the ground evenly in every part, as that when we ſtand thereon to rake in the Seeds, the feet will not ſink in holes, as would be the caſe at every ſtep in light ground, if not previouſly trodden; it alſo prevents the drought of the ſpring from penetrating too freely: but, indeed, if the ground is laid out in beds, we may either tread in the Seed or not, as we may readily ſtand in the alleys to rake them in without trampling the beds, which, in wettiſh ground in particular, may be the more eligible practice; however, even in the ſowing in beds immediately on the ſurface, as above, in light looſe ſoils, with a dry ſurface and dry ſeaſon, it is eligible enough to tread in the Seed, previous to raking the ground after ſowing; which work of treading in the Seeds, in both the above methods of ſowing, is performed with the feet nearly cloſe together, taking ſhort regular ſteps, treading the ſurface lightly all over, once in a place, with but ſmall ſpaces between the ſteppings.

Directly after the treading in the Seeds, as above, let the ground be regularly raked over to cover all the ſeeds effectually a proper depth, uſing a large wide-teethed rake for this purpoſe (ſee RAKE); being careful to rake very regularly, not to draw the earth and Seed in heaps, raking only once or twice in a place, which is generally ſufficient, eſpecially where the Seed has been previouſly trodden down in the above manner; taking care, however, to perform it ſo effectually as to bury all the Seeds properly: and as you advance in the raking, trim off lightly all large ſtones and rubbiſh.

Obſerving ſome Seeds require to be raked in as lightly as poſſible, ſuch as all the very ſmall Seeds; others require to be a quarter or half an inch deep, others a whole inch or more, ſo uſe ſmaller or larger rakes accordingly. See RAKE.

The above methods of Broad-caſt Sowing and raking in, may be practiſed to numerous ſorts of Seeds, particularly the greater part of the eſculents of the kitchen-garden: numerous flower ſeeds and others, as is generally hinted in their culture, and, being the moſt ready and expeditious mode of Sowing, is proper for general practice, eſpecially in extenſive grounds, except for ſome particular ſorts of Seeds that require to be ſowed either in drills or by bedding in, as directed below, which is particularized in treating of the reſpective plants in their proper places.

But in many of the extenſive kitchen-gardens in the vicinity of London, &c. where they ſow large tracts of ground at once, inſtead of raking in the Seed ſowed in the Broad-caſt way immediately on the ſurface, they, for the ſake of expedition and cheapneſs, have light ſhort-tined harrows to draw with men, with which they harrow in the Seeds; and ſometimes they afterwards roll the ground with a light wooden roller to cloſe and ſmooth the ſurface, in order to cover the ſeeds more effectually, performing it when the ſurface is a little dried ſo as not to adhere to the roller.

And in the large garden-farms in fields, where they commonly plow and harrow the ground for the reception of ſeeds, they practiſe only the broad-caſt Sowing in continued tracts for almoſt all their eſculent ſeeds, except for peas, beans, and kidney-beans, and not generally beſtow the work of treading down the ſeeds as before mentioned; but the ground being prepared by ploughing, and afterwards rough-harrowed, to ſmooth the ſurface moderately, the ſeeds are then ſowed broad-caſt, in the ſpreading open-handed manner, and then harrowed in either with a light horſe-harrow, or harrowed in with men for particular crops; then roll the ſurface afterwards with a wooden roller drawn alſo by horſes, &c. to ſmooth the ſurface, as aforeſaid.

DRILL SOWING.—This method of Sowing is neceſſary for many ſorts of ſeeds, both eſculents, flowers, and tree and ſhrub kinds in the nurſery, both for the plants to remain where ſowed, and for tranſplantation, and is performed by drawing drills with an hoe, from a quarter or half an inch, to

two

two or three inches deep, according to the ſizes and ſorts of ſeeds, which being ſowed evenly along the bottom of the drill, the earth is drawn evenly over them with a hoe or rake, the depths as above, and the ſurface lightly raked ſmooth.

As to the ſorts of ſeeds that may be ſowed in drills, numerous ſorts may with propriety be ſowed in that method, but is particularly eligible for many large kinds, ſuch as peas, kidney-beans; and many large kinds of tree and ſhrub ſeeds, nuts and berries; it being not only the moſt ready method of committing thoſe large ſeeds to the ground the proper depth; but being ſowed in rows at a diſtance, beſt ſuits the nature of growth of many ſorts of plants, and their method of culture. Many kinds of ſmall ſeeds are the moſt conveniently ſowed and cultivated in drills, ſuch as ſeveral of the kitchen-garden plants, as parſley, chervil, coriander, all the ſorts of ſmall-ſallading, and ſometimes ſpinach, beet, &c. alſo ſome of the aromatics when deſigned as edgings, ſuch as thyme, ſavory, hyſſop, and the like, which is generally mentioned in treating of their culture; likewiſe many ſorts of flower-ſeeds are the moſt commodiouſly ſowed in drills, both when deſigned for tranſplantation, and ſometimes to remain, as is exhibited under their proper genera: but many of the tree and ſhrub ſeeds, in particular, are the moſt conveniently ſowed in drills, all of which is properly noticed under the genera of the reſpective ſorts.

For by Sowing in Drills to all ſuch plants as admit of it, prove not only an eligible method of ſowing to bury all the ſeeds regularly an equal depth; but the drills being at ſome diſtance from one another, admits the ſun, air, and rains more effectually to the plants, and gives them a greater ſcope of growth, than ſuch as are ſown broad-caſt, or promiſcouſly all over the ſurface, but admits alſo of introducing a hoe between the drills to hoe down weeds and looſen the ſoil, which always proves a moſt beneficial culture.

The method of drill-ſowing is both eaſy and expeditious: in gardens it is performed by drawing the drills with a common drawing-hoe, large or ſmall, in proportion to the ſorts of ſeeds to be ſowed, generally ſetting a line as a guide to draw the drills ſtraight, which, as before obſerved, are drawn of different depths, from a quarter or half an inch to two or three deep, as the ſorts and ſizes of ſeed may require, and at proportionable diſtances, from three or four inches to ſo many feet, according to the nature of the plants; all of which particulars are always noted in the culture of the reſpective ſorts, under their proper heads.

The general method of drawing of drills for the reception of ſeeds, is with a common drawing-hoe, as before noticed, ſometimes with a large hoe, and ſometimes a middling or ſmall hoe, according to the ſize of the drill required, ſize and nature of the ſeeds; drawing the drill ſometimes with the corner of the hoe, eſpecially for larger ſeeds, and ſometimes with the edge of the hoe flat-ways or horizontally; but for large ſeeds, ſuch as peas, kidney-beans, many of the nut kinds, and other large ſeeds both of trees, ſhrubs, and herbaceous plants, require a deep angular drill, drawn with the corner of the hoe, turning the face or edge cloſe to the line, ſo draw the drill along with an angular bottom evenly the depth required, the earth remaining cloſe along the ſide of the drill, ready for turning in again over the ſeeds; but where flat or ſhallow drills are required for ſmaller ſeeds, it may, in many caſes, be more eligible to draw the drill with the hoe flat-ways, holding the edge in a horizontal poſition, as before obſerved, drawing the drill along with a flat bottom evenly the whole width of the hoe the proper depth, ſuitable to the ſorts of ſeeds intended to be ſo ſowed.

Sometimes, when very ſmall drills are required, we draw them with the end of the fingers, or with the end of a ſmall flat ſtick.

Having, however, drawed the drills in either of the above methods, the ſeeds ſhould generally be ſowed and covered in directly, if the ground is dry and in good order; but if the ſoil is wet, eſpecially at an early ſeaſon, it may be proper to ſuffer the drills to lie open expoſed to the ſun and air an hour or two, or more, to dry a little, particularly for tender ſeeds in early ſowings, as juſt above obſerved, ſuch as kidney-beans, &c.

As to the method of ſowing in the drills, it is performed for the general part with a locked or cloſe hand, diſcharging the ſeeds from between the fore-finger and thumb, as before related, ſcattering the ſeeds evenly along the bottom of the drill, ſome ſorts requiring

quiring to be ſowed thinly juſt along the middle, ſuch as in the angular drills drawed corner-ways of the hoe, for peas and many other larger ſeeds; alſo ſometimes for ſmaller ſeeds when intended for edgings; but in the ſhallow flat-bottomed drills it is generally intended for the ſeeds to be ſcattered evenly the whole width of the drill, thicker or thinner according to the nature of growth of their reſpective plants, proper hints of which are generally exhibited in their culture, obſerving to cover in the ſeeds generally as ſoon as ſowed, as already hinted, raking or hoeing the earth evenly over them, juſt the depth of the drills.

Remarking, the work of covering the earth in the drills over the ſeeds may be performed occaſionally both with the rake, hoe, and feet; but the rake or hoe is the moſt eligible for general practice, drawing the earth evenly into the drills a regular depth fully to the depth of the drill, whether deep or ſhallow; however as to peas, kidney-beans, and the like larger ſeeds in large drills at wide diſtances, they are often covered in with the feet, by ſlipping them lightly along each ſide of the drill alternately, turning the earth evenly in over the ſeeds; but generally for all ſmall ſeeds in cloſe drills it is proper to cover in with the rake or hoe, ſometimes uſing the teeth of the rake, and ſometimes the back occaſionally, as it ſhall ſeem moſt convenient; obſerving that as ſoon as the drills are covered in by either of the methods, let the ſurface be lightly trimmed along with the rake to ſmooth it and clear off large ſtones, &c.

In the huſbandry Drill Sowing, the drills are generally drawn with the drill-plow by horſes, which effects that work very expeditiouſly; and for ſome ſeeds is ſo contrived as to draw the drills, ſow the ſeed, and cover them in all at the ſametime.

Bedding-in Sowing.—This is a ſort of broad-caſt Sowing in beds, becauſe the ſeeds are ſowed all over the ſurface, but in a different way from the above mentioned: in this method the ground being digged and formed into four or five-feet-wide beds, with alleys, a ſpade width or more between bed and bed, and the earth being drawn off the top of the bed with a rake or ſpade half an inch or an inch or more deep into the alleys, the ſeed is then ſowed all over the ſurface of the bed; which done, the earth in the alleys is immediately drawn or caſt over the bed again over the ſeeds the ſame depth, and the ſurface raked ſmooth.

This mode of ſowing is often practiſed in the nurſeries, but not very frequently in kitchen-gardens, except in ſome parts of the North; it is not ſo expeditious as the broad-caſt Sowing, but is nevertheleſs very proper for many ſorts of ſmall ſeeds, and many ſorts of the tree and ſhrub kind, being a very regular method of Sowing ſo as to cover all the ſeeds an equal depth, and is performed two or three different ways, ſuch as by rake, by ſpade, and by ſifting.

In performing it by the rake, the ground is digged in the common way, raking the ſurface as you go on, afterwards marking it out into four-feet-wide beds with moderate alleys between bed and bed; then having a large rake, turning the teeth upward, and with the back thereof ſhove the earth evenly from off the ſurface of the bed, a quarter or half an inch, an inch or more deep, as may be required, into the oppoſite alley in a little ridge all the way along; this done, directly ſow the ſeed evenly all over the ſurface of the bed, then directly with the rake turned the right way, teeth downward, proceed to draw the ridge of earth out of the alley over the ſeed, ſtriking the teeth of the rake ſmartly down on the farther ſide of the ridge of earth, and drawing it toward with a kind of jerk, make the earth ſpread evenly over the ſeed quite from one ſide of the bed to the other, proceeding in that manner, drawing one ſtroke after another to the end of the bed; then proceed to the next in the ſame manner, and ſo continue bed and bed till all is finiſhed; then with a light rake gently trim the ſurface ſmooth and clear of ſtones.

In ſome places this method is practiſed almoſt in general in ſowing all ſorts of ſmall ſeeds, and by many preferred as a very eligible method of broad-caſt ſowing, ſo as to cover all the ſeeds evenly an equal depth; it, however, is not near ſo expeditious for large grounds as the common broad-caſt Sowing and raking in.

However, thoſe that are uſed to this method of Sowing rid it off a great pace; ſometimes two or three hands being employed on the ſame work, one ſhoves the earth from off the bed, another follows immediately after with the ſowing, and this followed directly

directly by a third, draws the earth over the ſeed, and ſo proceed bed and bed.

But nearly the ſame method of Sowing is alſo ſometimes performed with the rake and ſpade together, particularly in the nurſeries, when intended to ſow any larger ſeeds a good depth, uſing the rake to ſhove or rake the earth from off the bed, into the alleys; or if it cannot be conveniently performed with the rake a proper depth, it is effected with the ſpade, trimming or paring the earth evenly off the ſurface, half one way, half the other, into the alleys; then ſow the ſeeds all over the ſurface as before, and if they are of the larger berry, nut, or ſtone kind, or any other large ſeed, previous to covering them, preſs or pat them all evenly down into the earth, with the back of the ſpade; and then, either with the rake or ſpade, cover the earth out of the alleys evenly over them; though if it is a deep covering, eſpecially if taken off with the ſpade, it is moſt eligible to uſe the ſame implement in returning it, being careful to ſpread it evenly to cover the ſeeds all equally a proper depth, ſmoothing the ſurface with the rake.

Another method ſometimes practiſed in Bedding-in Sowing any common large ſeeds is, the ground being laid out in beds unraked, the ſeed is ſowed on the ſurface, and with the rake ſtrike it a little into the earth, then with the ſpade pare the alley, and caſt the earth evenly over the bed, half an inch, or an inch or more deep, as may be required, and rake the ſurface even. This is alſo ſometimes deſignedly practiſed in wettiſh ground, at an early ſeaſon, when it does not readily admit of treading or raking. And by deepening the alleys, and raiſing the beds, it drains the moiſture from the ſurface.

The method of Bedding-in Sowing, by ſifting, as formerly mentioned, is ſometimes practiſed for very ſmall or light ſeeds of a more delicate nature, that require a very light covering of earth when ſowed. So in order to bury them as ſhallow as poſſible, cover them in, by ſifting fine earth over them out of a wire ſieve. Previous to Sowing ſuch ſeed, the ſurface of the bed, &c. is raked fine; then either ſhove the earth thinly off the ſurface of the bed with the back of the rake into the alley, making the ſurface as ſmooth as poſſible, and then ſow the ſeed, and ſift the earth in the alley evenly over it, ſome very ſmall ſorts only juſt covered, not more than half a quarter or a quarter of an inch deep: or ſometimes the ſurface being only raked as ſmooth as may be, without drawing off the earth as above; and may alſo ſmooth it with the back of the ſpade, then ſow the ſeed, and let ſome fine earth from the alley, or ſome brought for the purpoſe, be ſifted thinly over it, as juſt above-mentioned.

SPADE.

A Spade is the moſt uſeful garden implement for digging, and preparing the ſoil for the reception of all ſorts of ſeeds and plants.

There are ſeveral ſorts and ſizes of ſpades occaſionally uſed, though the common large digging-Spade is, in moſt places, almoſt commonly uſed for all kinds of digging and Spade-work, which however in many inſtances, cannot be ſo conveniently uſed as a middling or ſmall Spade; it is therefore eligible for every good garden to be furniſhed with three different ſizes of Spades, to ſuit every department of gardening the more commodiouſly, ſuch as the common large digging Spade, for all common digging and Spade-work as above obſerved, and a middling, and a ſmall Spade for digging particular narrow compartments, and digging between ſmall plants cloſely placed in beds and borders, &c.—See each as below.

Common digging Spade, &c.—This is deſigned for all common digging, and trenching of ground, and all kinds of ſtrong Spade-work; ſo is of the largeſt ſize, being generally from fourteen to ſixteen inches long in the plate, and nine or ten broad, generally narrowing half an inch, or an inch leſs at the bottom. Though in ſome of the kitchen gardens about London, where the ground is light and deep, they uſe Spades full ſixteen or eighteen inches long in the plate, eſpecially the Batterſea Spades; however, for the general part, a Spade of fourteen or fifteen inches, by nine wide, proves the moſt handy ſize for all common digging in every diſtrict of gardening: but as they are made of different ſizes, from fourteen to ſixteen or eighteen inches long in the plate, as aforeſaid, ſo every one may ſuit himſelf according to the depth and nature of his ſoil, and method of working.

Middling Spade.—Being as to ſize, about a foot long in the plate, and ſeven or eight inches broad; which will prove very uſeful in digging any narrow compartments, and

between narrow rows of ſmall plants; alſo in flower beds, and borders; likewiſe in ſtirring, and freſh earthing the ſurface of beds occaſionally, between cloſe-placed plants of long ſtanding: planting and tranſplanting many ſorts, both in the ground, and in pots, and for many other ſorts of light Spade-work.

Small Spade.—The ſize ten or twelve inches long in the plate, and five or ſix wide, and is convenient in pointing up or ſlight digging, and freſh earthing the ſurface, between cloſe rows of ſmall plants, in beds and borders, &c. where none of the two former Spades can be readily introduced; likewiſe is uſeful in planting and potting many ſorts of ſmall plants, taking up ſmall roots, and other light purpoſes occaſionally.

Proper garden Spades have the plate wholly of iron, not above a quarter of an inch thick upward, growing gradually thinner from the middle downward; the tree or handle being generally of aſh, about two feet, and a half long, and an inch and half thick, with a firm open handle at top, formed out of the ſolid wood, juſt big enough to admit of taking ready hold, one hand at top, and the other below.

Semicircular, or ſcooped Spade.—Beſides the three ſorts of Spades above mentioned, there is alſo another ſort, having the plate made ſemicircular like a ſcooped garden-trowel, and is very uſeful in taking up plants with balls of earth, to preſerve the ball more firmly about the roots.

All the ſorts of Spades are ſold by moſt of the nurſery and ſeedſmen, and by the ironmongers; the prices being according to the ſizes, from five ſhillings to half a crown; the common digging Spades generally from four to five ſhillings, the middling ſize ones three ſhillings and ſix-pence, and the ſmall ſpades half a crown, or three ſhillings; ſo that the whole price of a ſet of ſpades is but trifling.

SPADICEUS *flos*, from *ſpadix*, a flower, or an aggregate of flowers, produced on that particular receptacle called a *ſpadix*, which is protruded from a ſort of calix called a *ſpatha* or ſheath, as in *Narciſſus*, *Amaryllis*, ſnow-drop, &c. See SPADIX, SPATHA, and SPATHACÆ.

Many of the bulbous and tuberous rooted tribe, produce Spadiceous Flowers, the principal of which are, *Amaryllis*, or lily daffodil, Guernſey lily, &c.—*Allium*, garlick, onion, leek, &c.—*Crocus*, all the varieties. —*Colchicum*, meadow ſaffron. — *Narciſſus*, daffodil; jonquils, &c —*Galanthus*, ſnow-drop. — *Leucojum*, greater ſnow-drop. — *Arum*, wake-robin, &c.—*Calla*, Æthiopian Arum.—*Orchis*, fool-ſtones, &c.—*Satyrium*, bee-flower.—*Ophrys*, twy-blade — *Dracontium*, dragon-plant. — *Hæmanthus*, blood flower. — *Crinum*, Aſphodel lily.— *Pancratium*, ſea-daffodil, &c. all of which are perennials, ſending up ſtalks annually, terminated at top by that kind of calix denominated a *ſpatha*, encloſing a *ſpadix* of flowers, and after obtaining a certain growth, the ſpatha or ſheath burſts open, and protrudes the ſpadix, ſupporting ſometimes but one or few flowers, and ſometimes many. See SPADIX.

Moſt of theſe plants are nearly allied, in habit and ſtructure, to the liliaceous tribe; diſtinguiſhed however, from that tribe of plants by their ſpatha or ſcabbard, out of which the ſpadix of flowers is protruded; the liliaceous kinds having no ſpatha, nor any other calix whatever.

SPADIX.

The particular receptacle and pedicles of ſpadiceous or ſpathaceous flowers above deſcribed, being protruded out of that kind of calix called a *ſpatha*; and ſuſtains from one to many flowers, as in *Narciſſus*, &c. See SPATHA.

The *Spadix* was originally applied to palms only, but it is now extended to all receptacles and pedicles of flowers, whether ſingle or aggregate, that have a *ſpatha* or ſheath for their calix; which kind of calix being in form of a ſheath or ſcabbard, burſts lengthways and protrudes the Spadix. See SPATHA.

SPARTIUM, Broom.

Conſiſts of ſhrubby flexible plants, of the deciduous tribe, both hardy and tender, for diverſifying the pleaſure-ground, and greenhouſe collections; all of upright moderate growth, with long ruſh-like ſhoots, thinly garniſhed with trifoliate, and ſingle ſpear-ſhaped leaves, and numerous papilionaceous flowers.

Claſs and order, *Diadelphia Decandria*.

*Characters.*] CALIX is monophyllous, tubulous, heart-ſhaped, with a ſhort margin, having five ſmall denticles.—COROLLA, is papilionaceous, with five petals, conſiſting of a large obcordated, wholly reflected vexillum, two oblong oval wings ſhorter than the ſtandard;

ſtandard, annexed to the filaments, and a dipetalous, oblong, hairy carina, inſerted alſo in the ſtamina.—STAMINA, ten unequal, diadelphous filaments, with oblong antheræ.—PISTILLUM, an oblong hairy germen, awl-ſhaped, riſing ſtyle, having an oblong hairy ſtigma.—PERICARPIUM, a long, cylindric, obtuſe, bivalvous, unilocular pod, containing roundiſh ſeeds.

There are about ten ſpecies in this genus, all of ſhrubby growth; the firſt of which grows wild abundantly in England, &c. all the others are exotics, chiefly from Spain, Portugal, Italy, and other ſouthern parts of Europe, and the Levant; about ſix or ſeven ſpecies are retained in our gardens for variety and ornament, in the ſhrubbery and green-houſe collection. Some of them being very hardy, others ſomewhat tender, requiring ſhelter of a green-houſe in ſevere winters.

*Hardy Kinds.*

About three or four ſpecies are hardier than the reſt, and ſucceed in the open ground in all weathers the year round: the firſt of which is our common Engliſh Broom, and the others are originally from abroad, the countries above-mentioned.

[1]SPARTIUM *Scoparium.*

*Common Sweeping Beſom Broom.*] Riſes with a ſhrubby flexible ſtem, and numerous, angular, ſmooth, green, flexible branches, five or ſix feet high; ternate and ſingle leaves; and numerous bright-yellow flowers all along the ſides of the young branches in May and June, ſucceeded by plenty of ripe ſeed in Autumn.

This plant grows wild in ſterile grounds in England, and moſt parts of Europe, and not very commonly admitted into gardens, only in ſome extenſive ſhrubberies, for the variety of its ſingular growth, and conſpicuous bloom of flowers. In the country it being made into beſoms, thence denominated Brooms; hence the name *Spartium Scoparium*, Sweeping Broom.

[2]SPARTIUM *Junceum.*

*Ruſhy Spartium, or Common Yellow Spaniſh Broom.*] Riſes with a ſhrubby ſtem, and taper, oppoſite, flexible, ruſh-like, green branches, eight or ten feet high; ſmall lanceolate leaves; and the tops of the branches floriferous, being terminated by looſe ſpikes of large yellow flowers, from July till September, ſucceeded by plenty of ſeeds in autumn.

*Variety.*] Double-flowered Spaniſh Broom; producing large full double-flowers, but no ſeed.

[3]SPARTIUM *Radiatum.*

*Radiated, or Starry Italian Broom.*] Grows two or three feet high, with numerous angular oppoſite branches all around, aſſuming a buſhy growth; ternate, linear, cloſe-ſitting, oppoſite leaves, having the folioles ſpreading round the ſtalks in a radius; and cluſters of yellow flowers at the ends of the branches, appearing in June and July.

Of the above three ſpecies, the two latter are the moſt commonly cultivated; having been long reſidents of our ſhrubberies: all three however, ſucceed any where, producing abundance of flowers and ſeed annually; and from the ſcattered, or ſelf-ſowed ſeeds, many young plants often riſe without care, the following ſpring.

*Tenderer Kinds.*

The following ſorts being rather of a more tender nature, eſpecially while young, are often potted, and treated as green-houſe plants; yet they moſtly ſtand our moderately ſharp winters, tolerably in the full ground; it is however, proper to pot ſome for ſhelter in winter, and plant ſome in the full ground in a warm ſituation, to take their chance.

[4]SPARTIUM *Monoſpermum.*

*Monoſpermous, or Single-ſeeded, White Spaniſh Broom.*] Grows ſix or eight feet high, with numerous angular, ruſh-ſhaped, ſilvery branches; ſmall ſpear-ſhaped leaves; and lateral cluſters of white flowers at the ſides of the branches, in July and Auguſt; ſucceeded by pods containing a ſingle ſeed only.

*Variety.*] With yellow flowers.

This ſpecies being moderately hardy, is very commonly planted in the open ſhrubberies, as a hardy flowering ſhrub; it is however, proper to retain ſome alſo in pots, eſpecially while young, to have occaſional ſhelter from ſevere froſt.

[5]SPARTRUM *Spinoſum.*

*Spinous Italian Maritime Broom, or Prickly Cytiſus.*] Grows five or ſix feet high, with angular ſlender branches, armed with ſpines; ternate, thinly-placed leaves, and cluſters of bright-yellow flowers at the ends of the branches, in June and July.

[6]SPARTIUM *Scopius.*

*Scopius, or Spreading Prickly Spaniſh Broom.*] Hath ſpreading ſpinous branches, oval leaves,

and largiſh yellow flowers, in July and Auguſt.

7 SPARTIUM *Angulatum.*

*Angulated Eaſtern Broom.*] Grows ſix or eight feet high, with numerous ſexangular branches, garniſhed with ſingle and ternate leaves; and the tops of the branches floriferous, being terminated by looſe ſpikes of pale-yellow flowers, appearing in July.

All the above ſeven ſpecies of *Spartium*, riſe with ſhrubby durable ſtems and branches, moſtly of a flexible nature, the branches in particular being very ſlender and pliable, producing long ruſhy green ſhoots, generally, however, aſſuming an erect growth; the leaves generally ſmall, and thinly placed, and the flowers moderately large and conſpicuous, all of the papilionaceous or butterfly kind, with five petals, as in the *Characters*, and moſtly of a ſtrong agreeable odour; ſucceeded by long cylindrical leguminous ſeed-pods, ripening in autumn: though ſome of the foreign ſorts do not always ripen plentifully in England, but are obtained in abundance from Spain, Portugal, and countries adjacent.

They all grow naturally in moſt of the ſouthern parts of Europe; and the firſt ſort, *Spartium Scoparium*, alſo in great abundance in this country, in barren uncultivated lands, often proving a moſt troubleſome plant to extirpate in grounds intended for cultivation.

As to the merit of all theſe ſhrubs, in gardening they may be all employed as flowering ſhrubs, or furniture to embelliſh the ſhrubbery compartments; the Common Spaniſh Broom, Radiated, and Monoſpermous kinds, &c. particularly, are the moſt common ſorts in the Engliſh gardens; and the *Spartium Scoparium* is alſo often thinly interſperſed in extenſive ſhrubberies, to encreaſe the variety: but all the ſpecies, both hardy and tenderer kinds, may be exhibited in the ſhrubbery plantations; being careful however, to ſtation the tenderer ſorts in the warmeſt ſituation, to take their chance of all weathers the year round, in common with the hardieſt kinds.

It is, however, alſo proper to have ſome of the tenderer kinds always in pots, to be treated as green-houſe exotics, for the greater certainty of preſerving the ſpecies, in caſe the others in the ſhrubbery ſhould ſuffer by the ſeverity of rigorous winters.

Moſt of theſe plants having long naked or thinly fibrated roots, often inclining to run down with a long tap-root, ſhould generally be planted where they are finally to remain while young, as they do not ſucceed well, if removed when large and old.

They are raiſed in abundance in all th public nurſeries for ſale.

*Method of Propagation, &c.*

They are all propagated by ſeed in the full ground, ſowed in the ſpring of the year; and the double-bloſſomed varieties, &c. by layers and cuttings.

Some of the ſorts ripen plenty of ſeeds in this country, but that of all the ſorts is procured in abundance by the nurſery and ſeedſmen for ſale; which ſhould be ſowed in the beginning of April, in four-feet-wide beds of common earth, either in drills near an inch deep, or bedded in that depth; they will ſoon germinate, and the plants riſe freely in a ſhort time, giving occaſional watering, and weeding all ſummer; and in winter, it is eligible to hoop the beds of the tenderer ſorts, in order to be matted in froſty weather; and in the ſpring following, it is adviſeable to prick out the whole in nurſery-rows, it being proper to remove them out of the ſeed-beds, when but one year old, on account of their tap-root aforeſaid, which ſhould now be ſhortened; then plant them in rows two feet aſunder, and one foot apart in each row; here to remain two or three years, then tranſplanted finally into the ſhrubbery; planting alſo ſome of the ſeedlings of the tenderer kinds, immediately from the ſeed-bed into pots, and placed in the green-houſe in winter.

Obſerve however, in raiſing the tenderer ſorts, that, for the greater certainty of ſucceſs, it will alſo be proper to ſow ſome in pots, plunging them in the ſhade all ſummer; where the plants will come up freely, being careful to remove them under a garden-frame, or green-houſe in winter, to have ſhelter till ſpring, then pot the ſeedlings off ſeparately as above, in order to be managed as hardy green-houſe plants; and in a year or two, having acquired ſtrength, ſome of them may be turned out into the full ground.

By Layers and Cuttings.—The double bloſſomed Spaniſh Broom, and the other varieties, not continuing the ſame from ſeed, muſt be propagated by layers or cuttings, to preſerve the ſorts with certainty. Make the

layers

layers in autumn or ſpring, and plant the cuttings in ſpring or ſummer, ſome in the full ground, others in pots, and plunged in a hot-bed to forward their rooting.

SPATHA, a Sheath.

Being the common calix of the ſpadiceous flowers; and which, being in form of a ſheath or ſcabbard, burſts open on one ſide, longitudinally, from bottom to top, and protrudes the *ſpadix*, a ſort of receptacle and pedicles ſuſtaining the flowers, conſiſting ſometimes of but one, and ſometimes of many florets. — See SPADICEUS *Flos*, and SPADIX.

Examples of the Spathaceous plants are *Narciſſus*, *Amaryllis*, *Galanthus*, and *Crocus*, &c.—See SPADICEUS *Flos*.

The *Spatha* always terminates the main flower-ſtalk, is moſtly of an oblong form, and ſometimes globular, as in onion and leek, &c. cloſely incloſing the *ſpadix*, till the flower acquires maturity enough to burſt it open, and conſiſts either of one piece, as in the greater number of ſpathaceous plants; of two, as in ſome few ſorts; or of a number of ſcales placed imbrication, as in the plantain-tree.

SPATHACEÆ *Planta*, (from *ſpatha*, a ſheath).

Spathaceous plants, ſuch whoſe flowers are protuded from a *ſpatha* or ſheath. See SPATHA.

SPAWN, a progeny or off-ſpring.

In gardening, is often applied to ſuch ſmall off-ſets, ſuckers, and ſprouts that riſe numerouſly from the roots, &c. of certain plants, ſerving for the purpoſe of propagation.

Therefore this ſmall Spawn, or off ſpring of vegetables, may be conſidered as parts ſimilar to the whole plant, as that being ſeparated from the parent vegetable, and planted, they readily grow, and commence proper plants, and thereby renew or propagate their reſpective ſpecies with great facility and abundance.

But Spawn among gardeners, in the general acceptation, is more peculiarly applied to the progeny of muſhrooms, being an off-ſpring from the root of thoſe *fungi*, conſiſting of minute white parts, ſhooting and running in the earth or dung, like ſmall white, thready fibres, aſſuming the appearance of long white ſtrings, productive of numerous minute white knobs, appearing at firſt the ſize of ſmall pin-heads, the whole ſmelling ſtrong of the muſhroom; and thoſe little knobs being infant plants, they gradually increaſe in volume to proper muſhrooms, which are quick of growth, and of very ſhort duration; but the ſame Spawn running in the earth, &c. furniſhes a plentiful ſupply of muſhrooms from the bottom in regular ſucceſſion, for a conſiderable time, ſometimes for ſeveral months.

So that muſhrooms propagate in great abundance by this Spawn detached from the root; and is the only method of propagation yet diſcovered, for raiſing them by the progreſs of horticulture; for the lumps of ſpawny earth or dung being planted in a ſort of hot-bed of horſe-dung, the ſpawn ſoon vegetates, and increaſes conſiderably, furniſhing muſhrooms in a ſhort time fit to gather; theſe hot-beds in which we depoſit the muſhroom, being always made with new horſe-dung from the ſtables, previouſly fermented in a heap, to evaporate the firſt violent heat, then formed in a long narrow ridge five feet wide and four high, like the roof of an houſe to ſhoot off the wet; and having remained open, and expoſed to the weather two or three weeks, till the great heat abates, the lumps of Spawn are planted all over every part of the bed at little diſtances, juſt within the ſurface; and the bed is then earthed all over an inch or two thick, and cloſely covered a foot thick, with dry litter; thus the moderate heat and peculiar quality of the dung, ſets the Spawn a-working, ſo as often to produce plenty of muſhrooms in ſix or eight weeks: and the ſame bed frequently continues furniſhing a ſupply five or ſix months, or longer; but new beds muſt be made every year or oftner; and the old ones pulled to pieces, ſaving all the good freſh Spawn thereof, for ſpawning future beds.—See AGARICUS *Campeſtris* in the *Addenda*.

Thus, through the effects of the peculiar warmth and quality of horſe ſtable-dung, the litter, and plenty of the ſhort ſtuff together, formed into a hot-bed as above, the muſhroom Spawn encreaſes, furniſhing both muſhrooms, and a plentiful ſupply of young Spawn for future beds: likewiſe any common horſe-dung hot-beds, horſe-dunghills, &c. moderately rotted, is often productive of a great deal of good muſhroom Spawn naturally; probably from ſome fine ſpawny matter, or the muſhroom ſeed having accidentally

cidentally mixed in the dung or earth, &c. And thus the Spawn produced by either of theſe effects, is the only certain reſource yet known for propagating that ſpecies by art, no ſeed having as yet been ſufficiently diſcovered, by which we can raiſe this plant; but the Spawn from the root, being as it were living fœtuſſes or infant plants, which renew their ſpecies as certainly as ſeed.

However, beſides this Spawn or off-ſpring of the root, the naturaliſts are agreed that muſhrooms have alſo generative organs, and produce flowers and ſeed like other plants, and naturally propagate themſelves alſo by ſeed, as well as by the Spawn; but from the exceeding minuteneſs both of the genital organs and ſeed, and their great obſcurity, or concealed ſituation, they yet remain inviſible; though it is ſuppoſed they are contained in the *lamellæ* or gills of the muſhroom, and which, when full-grown, diſcharges the ſeed upon the adjacent ground, and thence probably ſome is diſſeminated by the winds, &c. to other diſtant ſoils and ſituations adapted to their growth; and penetrating into the earth, grow and become muſhrooms, the roots of which multiply and furniſh proper Spawn alſo for the work of propagation.

But it was long the opinion of many, that muſhrooms never poſſeſſed the power of propagation at all, but ſuppoſed to owe their exiſtence to the putrefaction of earth, dung, &c. which doctrine, however, the modern botaniſts have ſufficiently refuted.

For muſhrooms being proper plants, they, either by Spawn or ſeed, or both, propagate themſelves like other vegetables; and it is probably from the diſſemination of the ſeed, by ſome myſterious progreſs of nature, to peculiar ſoils and ſituations, that we often find both muſhroom Spawn, and muſhrooms growing in obſcure places, where none ever grew before.

By Spawn, however, in particular, it is obvious that muſhrooms propagate themſelves plentifully, and by which, with proper garden culture, we can raiſe abundance of muſhrooms at pleaſure.

Therefore the muſhroom cultivators always furniſh themſelves with a ſufficient quantity of freſh Spawn every year, for every new bed, procuring it all times of the year, but more plentifully towards the end of ſummer, and in autumn, from the places of its growth, ſuch as old muſhroom-beds; any old horſe-dung hot-beds, and horſe-dung-hills, that lay moderately dry, and remained undiſturbed at leaſt half a year, or a year or two; alſo ſometimes in old compoſt heaps, conſiſting chiefly of horſe-dung; in all of which the ſpawny ſubſtance diſcovers itſelf in dry lumps of dung and earth, which lumps ſhould be taken up entire, as hereafter noticed; likewiſe in ſtable-yards, in bye dry corners, where any quantity of horſe-dung has lain dry and undiſturbed any conſiderable time, lumps of Spawn are often obtained. It is alſo found in fine perfection, in the horſe rides belonging to great livery ſtables and horſe-dealers in and about London, &c. which rides being under cover to ſhelter them from wet, and the ground ſpread thick with the ſhort dung from the ſtables for the horſes to tread on, being generally permitted to remain ſome conſiderable time without cleaning out, and being always dry, upon examining towards the ſides next the wall, is frequently found moſt excellent muſhroom. Spawn in large cakes; likewiſe in horſe-mill tracks, where horſes are conſtantly employed in working the mill, and they dunging, &c. in the tracts, it being occaſionally ſwept up towards the ſides, and the bottom ſometimes permitted to lie ſome conſiderable thickneſs a long time, upon turning it up, are frequently found fine lumps of excellent ſtrong Spawn: alſo in kitchen gardens, where any piece of ground having been well dunged in the ſpring, with new or but moderately-rotted ſtable-dung, or old dry hot-bed dung, &c. probably having embryo Spawn already formed therein, and which dungs happening to be but ſlightly digged in, or covered but a moderate depth with earth, ſometimes is productive of cluſters of muſhrooms in patches, towards autumn in dry ſeaſons, and in which places we often find lumps of very good Spawn: remarking, that in all the above places the Spawn is met with occaſionally at all times of the year, but more certain and plentiful towards the end of ſummer, and in autumn, before periſhed by the wet and cold in winter; being found in dry lumps, and cakes of dung and earth, appearing, as before ſaid, white and ſtringy, ſmelling ſtrong of the muſhroom.

I have ſometimes had muſhroom Spawn produced naturally all over the ſurface of an old cucumber, or melon hot-bed in autumn, and

and having continued the frame and lights conſtantly over it all winter long, covering the ſurface of the mould thickly with dry hay in froſty weather, laying alſo dry litter round the outſide of the bed, have, towards ſpring, had a full crop of very fine muſhrooms: in one bed in particular, in which was a fine loamy earth, they were remarkably numerous, large, thick of fleſh, and of firm texture; and after this produce, gathered a fine parcel of Spawn.

But muſhroom Spawn is alſo obtained in rich paſture-grounds towards the end of ſummer, and in autumn, before the rain and cold commences; the months of Auguſt and September being generally the proper ſeaſon when the muſhrooms riſe naturally, ſerving as a direction to the place to find the Spawn; then careſully opening the ground, the Spawn will appear in the earth as above, which may be digged up in lumps, and carried home in baſkets for uſe; this field Spawn however, cannot always be ſo readily obtained in any conſiderable quantity; and as it is found only in paſture-grounds, it may be very inconvenient to break up, and ſpoil the ſward in ſearch of it; beſides, many poiſonous ſorts of *fungi* grow in the fields, alſo from Spawn; we ought to be cautious when we are gathering Spawn for muſhroom beds.

From the above hints of the places of growth of muſhroom Spawn, we may readily know where to obtain it in ſufficient quantity for the purpoſe of ſpawning muſhroom-beds.

But after all, garden or bed Spawn produced in any horſe-dung beds, heaps or lays of horſe-hung, &c. before-mentioned, is preferable to the field Spawn for garden culture, it generally producing much thicker, more fleſhy, and firmer muſhrooms, of a richer flavour.

Therefore, in demoliſhing old muſhroom-beds, it is incumbent on us to preſerve all the lumps of young freſh Spawn, alſo all ſuch we occaſionally meet with in any old dung hot-beds, dunghills, &c. laying the lumps up in the dry till wanted; rejecting however, any very old worn-out Spawn, as far as it can be diſtinguiſhed; and the virgin Spawn, or ſuch that has not been worked, generally yields the fineſt muſhrooms; for ſometimes, even the young off-ſpring Spawn, or ſuch that have been long worked from bed to bed, is apt to degenerate, there being often a very material difference in the goodneſs of Spawn; that which is freſh and full of heart, will often produce abundance of fine muſhrooms for ſeveral months in the ſame bed; but ſuch that is worn-out or degenerated, ſend up only a flaſh of trifling little heads at firſt, of no ſubſtance, and probably never produce any more to ſignify.

There is alſo a fruitful, and barren ſort of muſhroom Spawn; the former is diſtinguiſhed by the ſubſtance of the fibry or ſtringy white ſhoots, &c. and muſhroom-like ſmell, as before obſerved; but in the baſe ſort, the thready fibres are conſiderably more abundant, fine, and downy, often appearing like a fine white down, and being of no ſubſtance, produce only a flaſh of ſmall white *fungi* deſtitute of the fleſhy part, and which by the muſhroom-men is commonly called white-cap; and by not perfectly diſtinguiſhing it, many have been diſappointed in their crop.

It is obſervable that horſe or ſtable-dung, of all others is the moſt remarkable for promoting muſhroom Spawn, even often alone in the dung-heap, without any addition of earth, though having a ſmall portion of any earthy ſubſtance, it may probably have the greater effect; for new horſe-dung conſiſting of the wet litter, and the ſhort ſtuff together from the ſtables, but the more ſhort the better, and being collected in any conſiderable quantity, either in any common cucumber or melon hot-beds, or remaining in the dung-heap a conſiderable time, it often becomes of a certain agreeable temperament, peculiar to the growth of muſhrooms, eſpecially if it does not burn much by the firſt violent heat; and that after remaining from winter or ſpring, until autumn or ſpring following, or longer, it frequently furniſhes lumps of excellent Spawn.

Methods are ſometimes practiſed to obtain Spawn more abundantly by art, by the effects of horſe-dung, both in hot-beds and in compoſt heaps; ſometimes in the former caſe, by planting ſmall pieces of Spawn, or ſpawny earth along the top edge of the later cucumber hot beds in ſummer, or in the ſides of any horſe-dung heaps, having a little warmth remaining; ſo that the moderate heat of the dung in the bed or heap, ſets the

Spawn

Spawn a-running, as ſometimes both to produce a few muſhrooms in autumn, and encreaſe conſiderably for future uſe in ſpawning proper muſhroom beds. And in the ſecond caſe, it is performed by a compoſt of dung and loamy earth together; procuring in ſpring, or early in ſummer, a quantity of freſh horſe-dung, conſiſting of plenty of ſhort ſtuff, and a due proportion of long together; and caſting it together to ferment a fortnight or a month, that the rank burning vapour may paſs away; then having ſome loamy earth, or other good ſubſtantial mould, or any ſpawny ſoil from old beds, form the dung into a long narrow ridge, mixing ſome of the earth occaſionally towards the outſide, and in a fortnight or three weeks, the heat becoming quite moderate, cover the whole with a dry long litter to defend it from the wet, permitting the whole to remain ſome conſiderable time; and thus probably ſome generating ſubſtance of muſhrooms, either Spawn, or ſeed, or both, having by ſome means previouſly, and accidentally introduced itſelf in the compoſt, which by its certain warmth and quality promotes its vegetation, and encreaſe, as ſometimes in three or four months to furniſh a good quantity of eligible Spawn.

Obſerve, in collecting the muſhroom Spawn found occaſionally in all the aforementioned places of growth, the lumps of dung and earth, in which it appears ſhould be taken up as entire as poſſible in a baſket, and carried into ſome dry ſhed or other apartment, there depoſited till wanted; previouſly obſerving, that if the lumps of Spawn are any ways wet or very moiſt, they muſt be ſpread on the floor thinly a week, or fortnight, or more, till thoroughly dry: then may either plant it if the bed is ready, or lay it up cloſe in ſome dry corner of the apartment, or put it up in hampers; covering the whole thickly with dry litter or garden-mats: and here it may remain till wanted, for the purpoſe of ſpawning muſhroom beds; as it will retain its vegetating property ſeveral months: and the drier it is kept in moderation, the better it will improve in its vegetable faculty, and take more freely with the bed when planted.

About London good muſhroom Spawn is a valuable article among the kitchen gardeners, who raiſe great quantities of muſhrooms for the markets; and in conſequence thereof, ſome of their labourers make it their buſineſs, at certain times of the year, but more particularly in ſummer and autumn, to go about to different places collecting it, which generally pays them well for their trouble, as they find a ready ſale for it, from five or ſix to ten ſhillings per buſhel.

Whoſoever may have occaſion to purchaſe Spawn from the environs of London, will meet with it moſt readily in the Neat-houſe gardens near Chelſea; alſo in the neighbourbourhood of Lambeth, Batterſea, Hammerſmith, &c. alſo in Covent-Garden market.

It may be packed up in hampers, and ſent to any diſtance, either by land or water-carriage.

SPICA, a Spike.

A mode of inflorescence, or manner of flowering peculiar to many plants; conſiſting of a ſimple peduncle or flower-ſtalk, ſupporting many flowers all along its ſides, without any pedicle or partial foot ſtalk, but are ſeſſile, or ſet cloſe to the main ſtalk, generally in alternate arrangement.

But the florets of a Spike are alſo ſometimes ſingle rowed, and ſometimes double-rowed, &c.—When ſingle rowed (*Spica ſecunda*) the flowers are all turned towards one ſide; and double-rowed (*Spica diſticha*) when they ſtand two ways.

SPINA, a Spine or Thorn.

One of the armature of plants, and are protruded immediately from the wood, being an expanſion of the ligneous body; by ſome compared to the horns of animals, which adhere to the bones of the ſkull, ſo that the Spine or Thorn differ from the prickle, *aculeus*, which are detached only from the bark, and not ſo ſtrong and hard as Spines. See ACULEUS.

Spines are intended by nature as armour to certain plants, to keep off cattle and *other* animals that would injure them.

Thorns ariſe either upon the ſtem and branches, as in buckthorn, box-thorn, white-thorn, ſloe, wild plum, pear, orange, triple-thorned acacia, falſe-acacia, furze, and many others of the tree and ſhrub-kind; or on the leaves, as in holly, American aloe, acanthus, thiſtle, Adam's-needle, juniper, butcher's-broom, &c. On the calix, as in ſhiſtle, centaury and mud-apple; or on the ſeed-veſſel and fruit, as in thorn-apple, prickly ſpinach, &c.

Spines riſe either ſingly, as in moſt ſpinous plants; doubly or by pairs, as in many ſorts; and triple, as in the three-horned acacia.

By

By culture many plants loſe their Spines, as plum, pear, medlar, orange, citron, &c. and the leaves of holly by age.

SPINACIA, Spinach.

Spinach is a noted culinary herb of the annual tribe; valuable as an eſculent for its large leaves for various culinary purpoſes moſt times of the year; having broad triangular and roundiſh leaves, riſing in cluſters cloſe to the ground; ſucceeded by upright tall ſtems, ſupporting ſpikes and cluſters of ſmall apetalous male and female flowers on ſeparate plants.

Claſs and order, *Dioecia Pentandria.*

*Characters.*] CALIX, dioecious flowers, having in the males a calix, cut into five oblong, obtuſe, concave ſegments; and in the females is monophyllous and permanent, cut into four acute parts, two of them being very ſmall.—COROLLA, no petals.—STAMINA, five capillary filaments, with oblong didymous antheræ.—PISTILLUM, in the females a roundiſh compreſſed germen, and four hair-like ſtyles with ſimple ſtigmas. PERICARPIUM, no ſeed-veſſel; the ſeed is roundiſh, and lodged in the permanent calix, and is either thorny or ſmooth in the different varieties.

There are but two ſpecies in this genus, one of which only is cultivated, being the common culinary Spinach, comprehending two eminent varieties; namely,—triangular leaved, with prickly ſeed,—round-leaved, with ſmooth ſeed: the former being the hardieſt, is more valued for the winter crop; but the latter having larger, thicker, and more ſucculent leaves, is preferable for ſpring and ſummer.

The ſpecies is,

SPINACIA *Oleracea.*

*Oleraceous, or Common Culinary Spinach.*] Hath a ſomewhat ſpindly fibrous-root, crowned with a tuft of large, broad, triangular, and roundiſh leaves on foot-ſtalks, cloſe to the ground; and when it ſhoots for ſeed, riſes with upright, hollow branchy ſtalks three feet high, producing ſpikes, and cluſters of numerous ſmall, apetalous, greeniſh flowers, male and female, on ſeparate plants; ſucceeded in the females by roundiſh cloſe-ſitting ſeeds, in ſome armed with ſpines, in others ſmooth.

Remarking, the male plants generally produce their flowers in ſpikes, and the females in cloſe cluſters at every joint.

*Varieties.*] There are two remarkable varieties of this ſpecies, each of which was formerly conſidered as a diſtinct ſpecies; but the improved Linnæan ſyſtem makes them varieties of one and the ſame ſpecies, their ſpecific determination being in the cloſe-ſitting ſeeds, *fructibus ſeſſilibus*, which is exactly the ſame in both varieties; there is however, a pretty permanent diſtinction in their leaves and ſeed; one variety having triangular arrow-pointed leaves, and prickly ſeed; the other having roundiſh leaves and ſmooth ſeed, as below.

*Triangular Spinach with Prickly Seed.*] Hath large triangular arrow-pointed leaves, five or ſix inches long or more, being broad and angular each way at the baſe, running up to a narrow point at top; and the ſeeds are moſtly armed more or leſs with ſhort ſpines.

*Round Spinach with Smooth Seed.*] Hath large roundiſh or oval leaves, five or ſix inches broad or more, of a more thick, fleſhy, ſucculent conſiſtence; and the ſeeds more round, moſtly free from ſpines, and quite ſmooth.

Both theſe varieties admit of ſome variations in the ſhape and ſize of the leaves; the broadeſt and thickeſt leaved ſorts are conſequently ſuperior in goodneſs; remarking of the Round Spinach in particular, ſome will have roundiſh leaves, others oval or oblong, and one ſort exhibits itſelf with much rounder, broader, and thicker leaves than the others, generally of a more ſtocky and luxuriant growth, and ſtronger green colour, and is the moſt valuable variety of the round-leaved kind: but obſerving both of the triangular and round-leaved varieties, we ſhould endeavour as much as poſſible, to mark the moſt ſtocky and broad-leaved plants to run up for ſeed, in order to obtain and continue the proper breed of ſuch eligible varieties only, ſufficiently for general culture.

As to the merit of each variety;—the triangular Spinach being of a more hardy nature, is generally cultivated for the main winter crops; and the round-leaved ſort claims precedence for the ſize and thick conſiſtence of its leaves, but being not quite ſo hardy as the other, it is cultivated principally for the ſpring and ſummer crops.

Both the varieties are herbaceous annuals, that ſucceed in the open ground, requiring to be raiſed annually from ſeed ſowed in an

open ſituation, in ſpring, ſummer, and autumn, to remain when ſowed; and the plants coming up in a fortnight, they attain perfection for uſe in two or three months, then run up to ſtalk, producing flowers and ſeed, and totally decay, root and all, the ſame year; though if ſowed in autumn, they come up and ſtand the winter till next ſpring, but not longer than April or May, before they run to ſeed, and periſh as ſoon as it is ripe.

They commonly flower in June, and when in flower, the male and female plants are then diſtinguiſhable, the former generally producing the flowers in ſpikes, having the flowers furniſhed with the ſtamina, ſuſtaining a yellow farina, being the male duſt for the impregnation of the flowers of the female plants, which have no ſtamina, only the female organs, the germen and ſtyles, on which the male plants naturally diſcharge their farina, and ſoon after after decay; but the female plants continuing their growth, and being thus fecundated, the embryo ſeeds grow faſt to perfection, being alſo thereby fertilized or rendered prolific, as that when ſowed they will readily grow, for without the vicinity of the male-flowers, many of the females would prove abortive, and all the ſeeds ſterile, which determines how neceſſary it is in Spinach, and other dioecious plants, to leave a ſufficiency of the males to impregnate the females.

Spinach is obtained for uſe almoſt the year round by different ſowings, from January till Auguſt or September; at about a month's interval between the early ſowings, two or three weeks in the main ſpring crops, and not more than a fortnight in ſummer; for the plants of each crop of the ſpring and ſummer ſowings will not continue longer for uſe, before they will fly up to ſeed; but the autumn ſowings, performed from about the middle or latter end of July, to the middle or end of Auguſt, do not run ſo ſoon, more eſpecially thoſe ſowed in Auguſt, which is the only proper ſeaſon for ſowing the winter crops, and which coming in for uſe in October, continue all winter and ſpring, until May, then ſhoot up to ſeed; being ſucceeded abundantly by the ſpring-ſowed crops, as above.

As to the culture of Spinach it is very eaſy: both the varieties may be raiſed in any ſituation from ſeed, ſowed either broad-caſt and raked in, or in drills; the plants remaining where raiſed, require only a little thinning and clearing from weeds; however, there being ſeveral material hints neceſſary to be generally known, in order to obtain Spinach in full perfection in the different ſeaſons of the year, we will therefore treat of its culture pretty fully; firſt exhibiting hints for its general culture, afterwards the culture of each variety, ſeparately in the different ſeaſons.

### *Hints of its Propagation and General Culture.*

The propagation of Spinach is effected only by ſeed, as being an annual, ſowing it every year in ſpring and autumn; the former ſeaſon of ſowing furniſhing the main-ſpring and ſummer-crops; and the autumn ſowings in Auguſt furniſhes Spinach all winter, and for early ſpring uſe, until May.

It may be ſowed at ſeveral intervals of time, from January till Auguſt, as every month, three weeks, and fortnight, according to the earlineſs or advanced period of the ſeaſon, ſo as to obtain a regular ſucceſſion of Spinach moſt part of the year; the ſpring and ſummer ſowings attaining perfection for uſe from April till Auguſt or September, and run to ſeed, and totally periſh the ſame year; but the autumn ſowings in Auguſt being deſigned not to come in for uſe till October, in order that it may remain all winter, and the following ſpring, until ſucceeded by the ſpring-ſowed crops, as before remarked.

Obſerve of the ſpring ſowings, that as the very early ſowings in January run ſoon to ſeed, ſhould ſow but a moderate quantity; but may ſow freely in February, March, and April, every three weeks, for the main-ſpring crops, which will ſupply plenty of young Spinach in great perfection, from April or May, till towards midſummer.

But if Spinach is required throughout the ſummer, continue the ſowings every fortnight, all May, June, and July; though the ſummer-ſowed Spinach rarely attains full perfection, like the ſpring ſowings, as it runs haſtily up to ſeed; but ſhould ſow frequent, and but little at a time.

And as to the autumn ſowings, as the plants do not run the ſame year, ſhould always ſow a good full crop to ſtand for winter, and early ſpring uſe, as aforeſaid.

With

With reſpect to the ſoil and ſituation for the culture of Spinach, it ſucceeds in any common ſoil of a kitchen-garden, but the richer in dung the better; for a well enriched ſoil makes great difference in the growth of Spinach, by exhibiting the plants of a luxuriant growth, in reſpect to ſize and thick conſiſtence of the leaves, a material excellence to be regarded in Spinach; always chuſing an open ſituation, not too near low-ſpreading trees, &c. for Spinach never ſucceeds in cloſe or ſhady places, in which it always draws up weak, and ſoon runs to ſeed, without attaining perfection; but having a free expoſure open to the ſun and air, encourages a ſtocky growth, and large expanſion of its leaves. A warm border may be proper for the early crops, but for the main crops in general, the open quarters is the moſt eligible; though a broad warm-lying border may alſo be proper for ſome part of the later ſowed winter-crops occaſionally, for the ſake of having the advantage of a little ſhelter of the fence, and benefit of the ſun during the winter ſeaſon.

Let freſh ſeed not more than a year old be procured for each ſowing, for this will be found of much importance in the free growth of the plants; and for the autumn ſowings of the winter crops, it is of advantage to procure new ſeed of the ſame year's ſaving, if poſſible.

The ground being digged, the ſeed may either be ſowed broad-caſt and raked in, or in ſhallow drills a-foot aſunder; though broad-caſt is the moſt expeditious, and probably the moſt eligible method for the growth of the crop; ſowing it all over the ſurface moderately thin, either in one continued plat, and trodden down evenly, if light ground, and raked or harrowed-in with a large rake, or light harrow; or may divide the ground into four or five-feet-wide beds, with foot-wide alleys between; more eſpecially for the early and winter crops in wet ground, and the ſeeds being ſowed as above, rake them in evenly: but drill-ſowing may alſo be occaſionally practiſed, drawing the drills with an hoe flatways, near an inch deep, and ten or twelve inches aſunder, ſcattering the ſeeds thinly along the drills, and rake the earth over, full half an inch deep, which mode of ſowing Spinach may be more particularly eligible, when obliged to ſow between other crops; it alſo more readily admits of hoeing up the weeds between the rows; and if ſowed thin, and the plants alſo thinned proportionably, they will grow as large and fine as in the other method of ſowing, and the produce very conveniently gathered; ſo that drill-ſowing of Spinach, the ſpring-crops particularly, may alſo be effected occaſionally, between other crops already growing in rows; as beans, cabbage, cauliflowers, &c. and may likewiſe be ſowed in wide drills alone; i. e. the rows a yard aſunder, to admit of intercropping in the intervals with rows of cabbages, beans, and other things occaſionally: however, the broad-caſt ſowing being the moſt ready and expeditious, and generally alſo the moſt advantageous for making the moſt of the ground when neceſſary, is the moſt commonly adopted method of ſowing Spinach, for large tracts of ground eſpecially. See SOWING of SEEDS.

Obſerve, in either of theſe methods of ſowing Spinach, to ſcatter the ſeeds moderately thin, as the plants at any rate require to be thinned to three or four inches diſtance at leaſt; do not however ſpare ſeed in a moderate way, and let it be directly raked or harrowed in, previouſly obſerving of that ſowed broad-caſt all over the ſurface, if in light looſe land particularly, it may be proper firſt to tread the ſeed evenly down, then rake it effectually with a large rake; and of that ſowed in drills, rake the earth evenly over it the depth aforeſaid, and rake the ſurface ſmooth.

Theſe ſeeds quickly germinate, and the plants will come up in a fortnight, or perhaps, if ſowed very early in ſpring, it will be three weeks or a month before they come up.

Obſerving however, in reſpect to their culture, that when the plants have three or four leaves an inch broad, they ſhould be thinned and cleared from weeds, performed either by hoe or hand, but the former is the moſt eligible; chuſing dry weather, and cut out the plants to three or four inches diſtance, together with all the weeds in every part; the above diſtance however, is ſcarcely ſufficient, unleſs intended to begin thinning out the plants for uſe while young, otherwiſe it is adviſeable to hoe them out ſix or eight inches aſunder; eſpecially the ſpring and ſummer crops of the round Spinach, which having proper room, will grow very

large, and ſpread its broad leaves widely around, and will not run to ſeed ſo ſoon as if left cloſe; for the ſpring and ſummer-ſowed Spinach in particular, if left too cloſe, draw up weak and trifling, and ſoon go to ſeed: but as to the winter crops of triangular or prickly Spinach, if thinned finally to four or five inches diſtance will be ſufficient. See their *Spring*, *Summer*, and *Winter Culture*, under ſeparate heads.

Spinach is often ſowed with other crops, for the ſake of cropping the ground to the beſt advantage when neceſſary; for a full crop of Spinach requires a large ſpace of ground, ſo as to furniſh any ſufficient quantity at each gathering; yet as being plants of low growth, and a temporary crop ſoon acquiring perfection, and each crop ſoon cleared off the ground for uſe, moſt of the London kitchen-gardeners and many others, who find it their intereſt in having as many crops from every ſpot of ground as poſſible, generally, to ſave ground, contrive to ſow the main ſpring crops of Spinach moſtly with ſuch other crops as admit of its growth without retarding or injuring one another, and grow to perfection in ſucceſſive order, out of one another's way; ſuch as with radiſhes and lettuce; and between rows of cabbages, cauliflowers, beans, and ſome other eſculents in wide rows, mixing nearly an equal quantity of the ſpinach and radiſhes, and only a ſmall ſprinkling of coſs-lettuce; ſowing the whole together broad-caſt, and rake them in; the radiſhes take the ſtart of the others, arriving to perfection before the Spinach, being then daily thinned out for uſe; and the lettuces are tranſplanted while young into another place, leaving the ground at laſt occupied only by the Spinach; unleſs the ground was alſo cropped with cabbages and cauliflowers, as is often practiſed.

For it is alſo cuſtomary among the kitchen-gardeners, in order to make the moſt of the ground, to ſow the main crops of ſpring Spinach and radiſhes, in February, March, and April, in the open quarters, where the general crops of cabbage and cauliflowers are intended; generally ſowing the Spinach and radiſhes firſt by broad-caſt all over the ground, and rake or harrow them in; then either directly, or in a week, fortnight, or a month after, as it ſuits, plant the cabbages and cauliflowers in rows at proper diſtances, as directed under their proper heads. See BRASSICA. They will ſoon take root, and get the ſtart of the Spinach and radiſhes, without retarding their growth; and the two latter will be all gathered off for uſe, by the end of May, and beginning and middle of June; when the ground is hoed to cut up weeds, looſen the ſoil, and draw up earth to the ſtems of the cauliflowers and cabbage-plants.

But the above methods of ſowing Spinach with other crops, is only recommended for occaſional practice in the aforementioned caſes; for in gardens where they are not neceſſitated to make the greateſt advantage of the ground, it may be more adviſeable to ſow the main crops moſtly alone, without the incumbrance of other crops; in which the Spinach will moſt likely attain the greater perfection: in this however, every one will ſuit his own convenience.

When the plants have leaves two or three inches broad, may begin thinning out ſome for uſe.

As to the method of gathering Spinach for uſe, it may either be cut up with a knife wholly to the bottom, if it wants thinning; or only crop the large outer-leaves, the root and heart remaining, ſhoots out again.

In gathering the ſpring crops however, we may at firſt, if the plants want thinning, cut them up wholly to the root, thinning them out where thickeſt in a gradual manner, ſo as to leave the ſtanding plants at laſt full ſix or eight inches diſtant to grow to perfection, which, when beginning to ſhoot for ſeed, may alſo be cut up wholly to the bottom.

And in gathering the winter crop of Spinach, if the plants ſtand too cloſe at firſt, ſome may be thinned out quite to the bottom; afterwards muſt only crop the larger outer leaves all winter, and early part of the ſpring; but when the ſpring is more advanced, and the plants grown large and require thinning, or when they begin to run to ſeed, may cut them up clean to the bottom.

Having thus exhibited hints for the general culture of Spinach, we now proceed to treat of the culture of each variety ſeparately, in its proper ſeaſon; firſt, the ſpring and ſummer crops; ſecond, the winter crop.

*Spring and Summer Crops.*

The round or ſmooth Spinach being the moſt eligible ſort for the ſpring and ſummer culture,

culture, for the reaſons before obſerved, February, March, and April is the principal months for ſpring-ſowing the main crops thereof; though to obtain a ſucceſſion of this ſpinach as early and late as poſſible, ſeveral ſowings may be performed, from January till Auguſt, as already obſerved.

The firſt ſowings may be performed in the beginning, or any time of January, if the weather is open; or, for the greater chance of ſucceſs, may ſow twice in that month if the weather permits, in a warm dry ſituation; ſowing only a moderate portion at this early ſeaſon, eſpecially in the beginning of the month, as it may be cut off by inclement weather; or if it ſurvives the froſt, the plants are apt to go to ſeed before they acquire their proper growth.

In February however, for the main ſpring crops, may ſow more freely in almoſt any open ſituation, eſpecially towards the middle of the month; it will however, be proper to ſow alſo twice in this month, at two or three weeks interval, which will enſure the greater ſucceſs of plenty in a regular ſucceſſion a long time, to ſucceed the winter crops, which will run to ſeed in April and May, about the time theſe ſowings arrive to the firſt ſtate of maturity for the table.

In March and April, it is alſo adviſeable to continue ſowing the ſame ſort of Spinach every three weeks, in an open ſituation, which will furniſh a regular ſupply for the table or market in May and June.

And in the months of May, June, and July, if a conſtant ſucceſſion is required all ſummer, it is proper to repeat the ſowings almoſt every fortnight during thoſe months, for theſe plants very ſoon ſhoot up for ſeed at this ſeaſon: chuſing for theſe ſummer-crops the ſtrongeſt moiſt ſoil the garden affords in a free ſituation, and if you can have the opportunity of moiſt weather for ſowing, it will be a particular advantage; being careful to ſow the ſeed rather thinner than common: and the plants ſhould alſo be hoed out thinner in proportion, otherwiſe will ſoon draw one another up into ſtalk for ſeed. Obſerving, that if a regular ſucceſſion is required to be extended alſo quite through the autumn, we muſt continue the ſummer ſowings till the middle or latter end of July; and thus we procure a conſtant ſucceſſion till the beginning of winter, or till ſucceeded by the winter crops in October.

With reſpect to the method of ſowing all the above ſpring and ſummer crops of Spinach, it may be principally by broad-caſt and raked in, or occaſionally in drills, as before obſerved in the *General Culture*.

We already obſerved ſome mix radiſh ſeed with the Spinach, in ſowing the main ſpring-crop, for the ſake of cropping the ground more advantageouſly; alſo ſowing it occaſionally on the ground intended for cabbage and cauliflowers, in all of which every one may ſuit his own inclination and convenience, agreeable to the hints before given.

As to the culture of theſe ſpring and ſummer crops of Spinach, it is nearly the ſame as obſerved in the general culture; that when the plants have three or four leaves an inch broad, hoeing them out in dry weather to about three or four inches diſtance, cutting up all weeds; and when they are advanced in growth, ſo as nearly to meet, they will be fit for the table: when they may be thinned out regularly, the largeſt for uſe, cutting them up cloſe within the ground; repeating the thinnings according as they are wanted for the family or market, and thoſe remaining at laſt having full ſcope, will attain great perfection.

After however, all theſe ſpring and ſummer crops attain perfection for uſe, they ſoon ſhoot up ſtalks for ſeed, and become uſeleſs; which renders a repetition of ſeveral ſowings neceſſary.

Some of the beſt plants of the February and March ſowed crops ſhould be left to run up, and produce ſeed for next year's ſowing. See *Saving the Seed*.

### *Winter Crop.*

Winter Spinach is the triangular or prickly ſort, as being the hardieſt, ſowed in the end of July or beginning of Auguſt, and arriving to perfection for uſe the ſame year, in the latter end of September, or in October; and ſtands without running all winter, ſupplying the table all that ſeaſon, and the following ſpring: being however, generally in good perfection all October, November, and December if mild weather, and often in moderate ſeaſons continues growing all winter long; is liable however to ſuffer by ſevere froſt; but the root and heart remaining ſound, it recovers ſtrength apace as the ſpring advances, and ſhoots out into large leaves

leaves abundantly till May, then it ſhoots for ſeed, being ſucceeded by the ſpring-ſowed crop.

It is therefore adviſeable to chuſe principally the triangular or prickly Spinach for this crop, as being the hardieſt to endure the froſt and wet in winter.

The proper ſeaſon for ſowing this crop, is principally the firſt and ſecond week in Auguſt, for if ſowed ſooner, it will get too forward, and be apt to run to ſeed the ſame autumn, or very early in the ſpring; however in cold or poor ſoils, in very expoſed ſituations, it is proper to ſow early in the firſt week of this month, as the forwarding the ſowings a few days in ſuch ſoils and ſituations is of importance, that the crop may get properly forward and obtain ſufficient ſtrength before the approach of winter. But in good rich warm-lying ground, if the ſowing is performed any time in the firſt fortnight of the month, it may be time enough; and in ſome of the rich grounds about London, they often ſow this crop of Spinach in the middle or latter end of this month, eſpecially for the later crop; however, it is moſt adviſeable to ſow the main winter crops rather early in Auguſt, which generally proves a very ſucceſsful ſeaſon in moſt ſituations for ſowing winter Spinach; obſerving, if ſhowery weather happen about this time, it will prove an advantageous opportunity for ſowing, as if ſowed in dry hot weather this ſeed is apt to riſe rather ſparingly and ſtraggling: do not however omit the proper ſowing ſeaſon as above.

Chuſe generally for this crop an open ſituation, that lies tolerably dry in winter, and that enjoys the winter's ſun.

And the ground being properly digged, immediately ſow the ſeed while the ſurface is freſh and moiſt, ſowing it generally by broad-caſt all over the ſurface, either in one continued plat to make the moſt of the ground, or in four or five-feet-wide beds, for the convenience of ſtanding in the alleys to do the neceſſary culture and gather the produce; and may ſcatter a ſprinkling of brown, Dutch, and common cabbage lettuce, &c. along with the Spinach ſeed, to take their chance for culling out in winter and ſpring: directly, as ſoon as ſowed, tread and rake it in evenly. Or the Spinach may be ſowed in drills, either at a foot diſtance for a cloſe crop, or three feet and a half aſunder, to allow of cropping between, in autumn with cabbages, or in winter or ſpring with beans, &c. But it is the cuſtom with moſt of the London gardeners, to plant early cabbages in moſt of their winter Spinach ground, more particularly that ſowed in the broad-caſt way in one continued plat, or that ſowed in wide-placed drills, planting the cabbage-plants generally in October, in rows three feet and a half aſunder at leaſt, they will continue their growth without impediment to the Spinach, which in ſpring being all cleared off for uſe, there remains a full crop of cabbages, &c. in good forwardneſs; ſo we thus both gain time and ground.

But with reſpect to the culture of this crop of winter Spinach, the plants coming up in a week or fortnight after ſowing, will in three or four weeks after that, when their leaves are an inch broad, want thinning and clearing froom weeds, performing it if poſſible by hoeing in dry weather, leaving the plants three or four inches aſunder, which will be room enough for the preſent, as ſome may afterwards be gradually thinned out for uſe, ſo as to leave them finally about four or five inches apart; afterwards, muſt only crop the leaves for uſe all winter, taking always the larger outer ones, and the ſmaller leaves in the center gradually expand themſelves in their turn for uſe in regular ſucceſſion all winter and ſpring; but in the ſpring, when the plants grow large and croud one another, or begin to ſhoot for ſeed, they may be cut up clean to the root.

Particular attention is required to keep this crop clear from weeds by occaſional hoeings and hand-weeding as may be convenient, being particularly careful to clear away chickweed, which is apt to infeſt this crop greatly in winter; always ſhaking the largeſt of the weeds entirely off the ground, which if left at this moiſt ſeaſon, would ſoon ſtrike root again and grow.

Towards ſpring, after the rigours of winter are paſt, take opportunity of a fine dry mild day, and lightly hoe the ſurface of the ground about the Spinach, which will greatly recruit the vigour of the plants, and in February and March will ſhoot out ſtrong, and attain fine perfection again for uſe: ſtill cropping only the largeſt outer leaves at firſt, unleſs they ſtand too thick, or when they begin to ſhoot for ſeed, as before hinted, then may be cut up by the root, as they are wanted,

wanted, leaving a portion to produce ſeed, as below.

*Saving the Seed.*

When intended to ſave Spinach ſeed, may allot a portion both of the ſpring and winter crops to ſtand and run up for that purpoſe.

Remarking, you may either ſow a quantity of both varieties on purpoſe, in ſpring and autumn, in an open ſituation to ſtand for ſeed; or may leave a parcel of ſome of the crops that were raiſed for uſe; obſerving of the ſpring-crops, chuſe principally that of the February or beginning of March ſowing, which will run up early, and ripen ſeed the beginning of autumn following: and as to the winter crops, they being not raiſed till Auguſt, do not ſhoot till the following ſpring; though as they run earlier to ſtalk than the ſpring-ſowed plants, they probably will ripen their ſeeds ſomewhat earlier in autumn.

Note, in the plants deſigned for ſeed, it may be of ſome advantage to have the two varieties, round and triangular Spinach, at ſome diſtance from another, leſt by the intercommunication of the farina it may cauſe a degeneracy.

Obſerve likewiſe, in the plants allotted for ſeed, ſhould draw out all the bad ſorts, preferring thoſe of the moſt ſtocky growth, with the largeſt, moſt expanded, and thickeſt leaves; thinning the whole eight or ten inches diſtance, and cut up all weeds.

They will begin to run up to ſeed-ſtalks in April and May: the winter crops generally ſhoot firſt, and are ſoon followed by the ſpring crops, flowering in June; at which time the male and female plants diſcover themſelves diſtinctly; leaving however the whole to nature, the males will ſufficiently fecundate the flowers of the female plants, ſo as the latter will be loaded with abundance of ripe fertile ſeeds, in the end of July or beginning of Auguſt.

When the ſeed is full ripe, which is obvious by its changing brown and hardening, the ſtalks muſt be pulled up, and ſpread to dry a few days, turning them occaſionally to dry, and harden all the ſeed properly: then threſh them out, and bag them for uſe.

This newly ſaved ſeed is excellent to ſow for the winter crop, provided it is ripe time enough; it however remains perfectly good for next year's ſowing, but is not to be truſted to if more than a year old.

SPIRÆA, *Spiræa frutex*, &c.

This genus is compoſed of ſhrubby and herbaceous plants, conſiſting of many beautiful, deciduous, flowering ſhrubs, and floriferous herbaceous perennials, all of hardy temperament; and eminent for decorating the pleaſure-ground, being of upright growth, adorned with ſpear-ſhaped, pinnated, trifoliate, and decompound leaves in the different ſpecies, and terminated by ſpikes and cluſters of pentapetalous flowers.

Claſs and order. *Icoſandria Pentagynia.*

*Characters.*] CALIX, is monophyllous, acutely quinquedented, and permanent.—COROLLA, five oblong roundiſh petals inſerted into the calix.—STAMINA, twenty or more ſlender filaments, having roundiſh antheræ.—PISTILLUM, five or more germens, ſupporting five ſtyles, having capitated ſtigmas.—PERICARPIUM, oblong, acuminated, compreſſed, bivalvular capſules, containing a few ſmall acuminated ſeeds.

There are eleven ſpecies of *Spiræa*, ſeven of them being ſhrubby, with durable ſtems, &c. and the other four are herbaceous, having durable roots, but moſtly annual in ſtalk. All the ſhrubby kinds are originally exotics, from different parts of the continent of Europe and North America; and of the herbaceous kinds, ſome are indigenous plants of England, others exotics; but all the ſorts, both ſhrubby and herbaceous, are very hardy, and moſt of them have been long inhabitants in our gardens for ornamenting the ſhrubbery, &c.

*Shrubby Kinds.*

Under this head is exhibited ſome very eminent hardy, deciduous, flowering ſhrubs, obtaining from about three or four to ſix or eight feet ſtature, moſtly with ſlender pliant ſhoots, ſome garniſhed with oblong ſimple leaves, others with lobated and pinnated foliage; and the branches terminated by ſpikes and cluſters of flowers of very ornamental appearance; hence theſe ſhrubs are in good eſtimation among the curious for embelliſhing the ſhrubbery compartments, particularly the firſt three or four ſpecies, which have been long reſidents of our gardens.

There being ſeven ſpecies of theſe ſhrubby *Spiræas*, are all originally from abroad, in different parts of Europe and America, but are

are all hardy enough to ſucceed in our open plantations.

The chief ſpecies are,

[1]SPIRÆA *Salicifolia.*

*Willow-leaved Siberian Spiræa, or Common Spiræa frutex.*] Riſes with many upright ſtraight, ſlender, reddiſh ſtems and ſuckers from the root, three or four feet high; garniſhed with ſpear-ſhaped, obtuſe, ſerrated, naked leaves; and the ſtalks terminated at top by doubly-branching racemous ſpikes of numerous pale-red flowers.

This is the moſt common ſort of *Spiræa*, is in high eſtimation as a flowering ſhrub; it flowering beautifully in June and July, and frequently the ſame year's ſuckers, from the root, flower alſo in Auguſt.

The young ſhoots of this plant being ſtraight, pliant, and tough, are often uſed for tops of fiſhing rods, and riding ſwitches.

[2]SPIRÆA *Tomentoſa.*

*Tomentoſe Red-flowering Philadelphian Spiræa.*] Riſes with upright, ſlender, branchy, purpliſh ſtems, three or four feet high; ſpear-ſhaped, unequally-ſawed leaves, tomentoſe or downy underneath; and the branches terminated by doubly-branching racemous ſpikes of beautiful red flowers.

*Variety.*] With white flowers.

Both the varieties flower in June and July, and are very beautiful.

[3]SPIRÆA *Hypericifolia.*

*Hypericum leaved Canada Spiræa, Commonly called Hypericum frutex*] Riſes with ſlender brown ſtems, branching numerouſly and ſlender almoſt from the bottom, five or ſix feet high; garniſhed with oval entire leaves, and numerous ſmall white flowers all along the branches, to the very ends of the twigs, in ſmall cloſe-ſitting umbels.

This ſhrub has ſingular beauty when in flower, as every branch and twig is cloſely covered with flowers their whole length; flowering in May and June, continuing very ornamental about a fortnight.

[4]SPIRÆA *Opulifolia.*

*Gelder-Roſe-leaved Virginia Spiræa.*] Riſes with many ſhrubby ſtems branching ſix or ſeven feet high, having a brown looſe bark falling off in winter; garniſhed with lobated or lobed leaves, like the gelder-roſe and currant leaf; and numerous white flowers in corymbeous bunches at the ends of the branches.

[5]SPIRÆA *Sorbifolia.*

*Sorbus-leaved Siberian Spiræa.*] Riſes with ſhrubby ſlender ſtems and branches, three or four feet high; pinnated leaves of four or five pair of folioles uniformly ſerrated; and white flowers in panicles at the ends of the branches, in July.

[6]SPIRÆA *Crenata.*

*Crenated leaved, Siberian and Spaniſh Spiræa.*] Riſes with ſhrubby ſlender ſtems, and numerous, ſlender, browniſh branches, four feet high; having oblong leaves ſerrated at the end, and white flowers in corymbous bunches laterally from the ſides of the branches in May.

All theſe ſhrubby *Spiraæs* flower here very ornamentally, from May till July, in different ſpecies; but rarely ripen ſeeds in perfection in England; they however are all eaſily propagated, ſome by ſuckers, and all of them alſo by layers and cuttings. See their *Propagation.*

*Herbaceous Kind.*

Conſiſts of four floriferous perennials of the fibrous-rooted tribe, riſing with herbaceous annual ſtalks, from one to three or four feet high, garniſhed with pinnated, ternate, and decompound leaves, and terminated by cymoſe bunches, and panicles of flowers; they are all perennial in root, but renew their ſtalks annually in ſpring, arriving to a flowering ſtate in June and July, produce ripe ſeed in autumn, and the ſtalks ſoon after decay.

There being four ſpecies of theſe kinds, the two firſt grow naturally in England, in paſtures, &c. and the others are foreigners, but are both very hardy.

[7]SPIRÆA *Filipendula.*

*Filipendula, or Drop-wort.*] Hath a fibrous root hung with numerous ſmall oval tubers, and crowned at top with a large tuft of pinnated leaves, of many reniform ſawed lobes ſpreading near the ground; and upright herbaceous ſtalks a foot or more high, terminated by cymoſe bunches of white flowers.

*Varieties.*] Common ſingle-flowered Filipendula of the paſtures, &c. — Double-flowered of the gardens.

The ſingle ſort grows wild in England, in paſtures and chalky grounds, but is alſo retained in gardens as a flowery plant, in aſſemblage with the double ſort, which is very ornamental.

They flower in June and July, and the ſeeds ripen in autumn.

The

The root of this plant conſiſting of many thready fibres hung w th ſmall oval knobs, it obtained the name *Fi ipe idula.*

[8]SPIRÆA *Ulmaria.*

*Ulmaria*; *Meadow Sweet, or Queen of the Meadow.*] Hath a thick, fibrated, ſpreading root, upright, reddiſh ſtalks, three or four feet high; garniſhed with large pinnated leaves, of two or three pair of indented lobes, and an odd one, which is the largeſt of all, and lobated; and the ſtalks terminated by large cymoſe bunches of white ſweet-ſcented flowers, in June.

*Varieties.*] Common ſingle flowered of the meadows.—Double-flowered of the gardens.—Variegated-leaved.

The common ſingle ſort grows wild in moſt meadows in England, but is often allowed garden-culture along with the double and variegated-leaved ſorts; the flowers of all the varieties being very conſpicuous, and agreeably ſcented; but the double ſort in particular makes a fine appearance: they flower in June, and the ſeeds ripen in autumn.

[9]SPIRÆA *Trifoliata.*

*Trifoliate or three-leaved Virginia Meadow Sweet.*] Hath a fibrated root, upright, branchy ſtalks a foot high; garniſhed with almoſt equally ternate or trifoliate ſerrated leaves; and terminated with looſe panicles of white flowers in July.

[10]SPIRÆA *Aruncus.*

*Aruncus or Goat's Beard, or Auſtrian Spiræa.*] Riſes with upright firm ſtalks, three or four feet high; garniſhed with ſupra-decompound leaves; each diviſion conſiſting of three or four pair of foliola, and an odd one; and the ſtalks terminated by paniculated ſpikes of dioecious white flowers in July.

All the above ten ſpecies of *Spiræa* are very hardy, ſucceed in any common ſoil and ſituation, and are of long duration; the ſhrubby kinds being durable in root, ſtem, and branches, and deciduous in leaf; but the herbaceous kinds are durable only in root, and renew their ſtalks every ſpring; all the ſorts, both ſhrubby and herbaceous, flower abundantly every ſummer; the flowers ſeparately are ſmall, compoſed univerſally of five ſmall petals each, but being numerous and cloſely placed, are conſpicuous to view; but are rarely ſucceeded by ſeed in England in the ſhrubby kinds, though moſt of the herbaceous kind furniſh tolerable plenty in autumn.

As to the merit of all the ſorts in gardening, they are all proper furniture for ornamenting the ſhrubbery, and other parts of the pleaſure-ground occaſionally.

The ſhrubby kinds particularly have great merit as deciduous flowering ſhrubs, for embelliſhing the principal ſhrubbery compartments, placing them ſomewhat forward, in aſſemblage with other ſhrubs of equally moderate growth; and here they will exhibit a proper variety, and flower very ornamentally every ſummer.

And as to the herbaceous kinds, conſidered as flowery plants, particularly the doubles, are proper for adorning the common borders, &c. where they will flower every ſummer, and encreaſe the variety.

*Propagation, &c. of the Shrubby Kinds.*

The method of propagating all the ſhrubby kinds is very eaſy.—By Suckers, by Layers, and Cuttings.

By Suckers.—Several of theſe ſhrubby *Spiræas* are productive of many ſuckers annually from the root, which being taken off in autumn, commence good plants; but the firſt ſpecies in particular, *Spiræa Salicifolia, Willow-leaved Spiræa, or Common Spiræa frutex*, is remarkably prolific in ſuckers, that in one ſummer grow as high as the parent plant, and generally terminated by ſpikes of flowers the ſame year in autumn, and ſhould always be cleared off from the old plants every year or two in winter; as ſhould alſo the ſuckers of all the other ſorts: moſt of which ſuckers readily riſing with roots, they immediately commence proper plants, and the largeſt may be planted at once where they are to remain, and the others in nurſery-rows, to have one or two year's growth, and will then be fit for the ſhrubbery.

By Layers.—All theſe ſorts will grow freely by layers, but is a more particularly eligible mode of propagation for any of the ſorts that do not readily afford a ſufficiency of ſuckers; for almoſt every branch or twig being layed down in the earth, in autumn or winter will be well rooted, fit for tranſplantation by the autumn following.

By Cuttings.—Any of the ſhrubby ſorts will likewiſe grow by cuttings, though not to be depended upon like layers; however, in October or November, chuſing cuttings of the ſtrongeſt young ſhoots of laſt ſummer's growth, planting them in a ſhady border,

many of them will grow; and in one or two years commence good plants for the ſhrubbery.

*Propagation, &c. of the Herbaceous Kinds.*

All theſe ſorts may be propagated by ſeed, and by parting the roots.

By Seed.—This may be ſowed either in autumn ſoon after it is ripe, for the greater certainty of having them come up freely in the ſpring following, or may be ſowed early in the ſpring, as they will alſo often riſe the ſame year; keeping the plants thin, and clear from weeds till autumn, then planted out either in nurſery-rows for a year, or at once, where they are to remain.

By parting the roots.—All the herbaceous kinds may be propagated by this method in autumn, and is the only method of propagation for continuing the double-flowered and ſtriped varieties; obſerving, of all the ſorts, it may be performed either in autumn when the ſtalks decay, or early in ſpring before new ones begin to ſhoot forth.

SPROUTS.

Sprouts are ſmall young ſhoots or ſuckers, emitted from the ſides of the ſtem and heads of certain vegetables; being in many inſtances a compendium of the plant that produced them, and when detached from the parent and planted, although then deſtitute of roots, they often in the proceſs of vegetation emit fibres, ſhoot at top to mature growth, and exhibit leaves, flowers, and ſeed like the parent plant.

Likewiſe, in ſome herbaceous eſculents, young Sprouts are excellent eating, ſuch as in cabbages, &c. proving a very profitable after-crop.

But the term Sprouts is more generally applied to the lateral ſhoots or ſuckers of certain herbaceous vegetables; ſuch particularly, as moſt of the *braſſica* tribe, comprehending all the ſorts of cabbages, ſavoys, coleworts, borecole, purple broccoli, &c. which after the main head is gathered for uſe, the ſtalks remaining ſhoot forth abundance of Sprouts, that often form heads like the principal one but ſmaller; and, being detached and planted, will grow, or may be gathered for uſe as eſculents, and will prove equally good, and often ſuperior to the main-head for eating.

Theſe Sprouts however, of the cabbage-tribe, have merit chiefly as eſculents, and very little in the work of propagation.

For although they will grow if planted while young, they are only proper to be uſed occaſionally in particular caſes; as for example, in planting cabbages for ſeed in any particular good ſort, which having the main-head gathered early in ſummer for uſe; and the ſtalk having produced a quantity of good Sprouts ſoon after, we ſometimes ſlip off a quantity of the beſt of them towards autumn, plant them in rows two feet aſunder, giving occaſional waterings, will grow and ſhoot up to ſeed next ſpring. See BRASSICA.

However, the Sprouts of all the cabbage-tribe, conſidered as eſculents, are admirable fine eating, generally boil exceeding green and tender; but thoſe Sprouts produced from the forward cabbage-ſtalks in ſummer and autumn, are always larger and finer than the winter and ſpring Sprouts, as ſometimes the Sprouts produced on the ſtalks of the early-cut cabbages, often alſo cabbage into tolerable little firm heads towards autumn; the ſugar-loaf cabbage particularly, producing abundance of fine Sprouts in ſummer, which being gathered while young and green, are ſome of the moſt excellent culinary greens of the ſeaſon; likewiſe forward ſavoys being cut early in autumn, the remaining ſtalks produce fine large ſprouts the ſame year, fit for uſe in the early part of winter; later crops of the ſame plants produce alſo abundance of ſmall Sprouts in the ſpring; and the borecole is remarkable for its great production of Sprouts towards ſpring, emitted all along their tall ſtems from the very bottom to top; alſo purple broccoli never fails to produce a ſecondary crop of excellent Sprouts furniſhed with little tender heads.

Thus all theſe cabbage and colewort tribe, that after the main-heads being arrived to perfection and gathered for uſe, the ſtalks furniſh a plenteous ſupply of Sprouts, coming in for a ſecond crop; thoſe produced in ſummer and autumn continuing long in perfection; but the ſpring Sprouts run ſmaller, and continue but a ſhort time before they fly up for ſeed; they are nevertheleſs very acceptable and uſeful, at that ſeaſon of the year.

Therefore, in the culture of all the above varieties of the cabbage kind, it is proper after gathering the main-heads, to leave a quantity of the ſtalks of the beſt and forwarder crops, of the reſpective ſorts, to produce

duce Sprouts; and if towards autumn or winter, &c. the ground ſhould be wanted for other crops, the ſtalks may be removed and trenched in by the roots in another place, not in any ſhady bye corner as often practiſed, nor placed too cloſe, as the Sprouts would prove ſmall and trifling, and be liable to be eat up by ſlugs; but being placed in an open ſituation, in rows a foot aſunder, the Sprouts will continue their growth in much greater perfection, though probably not equally ſo good as if the ſtalks had remained undiſturbed.

Thus the product of Sprouts will prove a very beneficial and acceptable ſupply, both for uſefulneſs and variety at table.

The ſtalks of cauliflowers and cauliflower-broccoli, rarely produce any Sprouts, ſo it is needleſs to leave them ſtanding.

STAMINA, the male organs of flowers.

Stamina, conſiſting of the filaments and antheræ, the male organs of every flower; being the fine chives or thread-ſhaped parts ſituated in the center of the *corolla*, in number from one to twelve, or twenty or more; and compoſed of the three following parts.

[1]*Filamentum*, the filaments or thread-ſhaped parts elevating the antheræ. See FILAMENTUM.

[2]*Antheræ*, the ſummit of the filaments, and that part which contains the *pollen* or fecundating duſt or farina. See ANTHERÆ.

[3]*Pollen* or farina, the fine duſt, or fecundating male ſperm contained in the antheræ; and when ripe, diſperſed upon the ſtigma or female organ, to effect the important office of impregnation.—See ANTHERÆ and FILAMENTUM, &c.

It is obſervable in moſt flowers, that the Stamina and piſtillum come together; and the antheræ and ſtigma ripen and becomes of full vigour at the ſame time to effect the work of fecundation.

For the Stamina containing the genuine male ſperm of plants in the antheræ, that without its fecundation aid no plants would be effectually prolific, but moſtly abortive; at leaſt, if they produce ſeeds, they would not vegetate.

In hermaphrodite plants the *Stamina* or male organ being placed in the ſame flower with the female genitals, are for the moſt part all of equal height, generally ſurrounding the piſtillum in ſuch ſituation, as the farina or male ſperm lodged in the antheræ, may readily reach the *ſtigmata* of the female flower to impregnate it effectually; but in ſome hermaphrodite flowers the piſtillum being ſhorter than the Stamina, the flowers though nodding before, upon opening generally ſtand upright, that the powder of the antheræ may fall upon the ſtigma; and after conception probably reſume their drooping or pendulous poſture again; and in other hermaphrodite flowers having the ſtyle longer than the Stamina, it either bends back like ram's-horns towards the antheræ, or the whole flower droops that the antheræ may drop its duſt down upon the female organ. See HERMAPHRODITUS *flos*.

In monoecious plants, the Stamina and piſtillum are in different flowers, ſituated apart on the ſame plant, as in cucumber and melon; but in many ſorts have the male flowers moſtly placed above the female, that the farina or fertilizing powder may more readily fall on the ſtigma of the piſtillum: or ſo ſituated as to be eaſily conveyed by the air or flying inſects, ſkipping from flower to flower, ſufficiently to effect the impregnation. And in ſome plants, ſuch as cucumbers, growing in hot-beds at an early ſeaſon, we often perform the fecundation by art, carrying the male bloſſom to the female, and diſcharge the contents of the antheræ upon the ſtigma; but when the warm ſeaſon is advanced to admit of the plants being fully expoſed, that operation is effected by the air, or bees, conveying the proliferous duſt of the antheræ to the female bloſſom. See CUCUMIS and MONOECIA.]

And in the dioecious plants the Stamina and piſtillum are in ſeparate flowers, ſituated on different plants, ſpecies of the ſame genus, as in ſpinach, hemp, hops, &c. but ſo wonderfully contrived by the great Author of Nature, that the male duſt of the antheræ is conveyed to the female flowers by the gentle breezes of air, &c. and impregnate them. See the Claſs DIOECIA, under the head CLASSIS. See alſo SEXUS, PISTILLUM, STIGMA, and STYLUS.

STANDARD Trees.

Standard-trees are to be conſidered as all trees with upright ſingle ſtems, and ſtand detached without being trained to any wall, &c. or other ſupport.

The name Standard-trees is applicable both to all ſorts of fruit and foreſt-trees, and all other tree and ſhrub kinds that, having upright ſtems, ſtand detached erectly without aid of ſupport: though the word

Standard is more generally underſtood of ſuch trees as grow with tall erect ſtems, ſix or eight feet high, or more, before they branch out to form the head; ſuch as the common Standard apples, pears, and other fruit-trees in orchards and gardens, and the common foreſt-trees of the woods and fields; in gardening, however, we commonly diſtinguiſh three ſorts of Standard trees; namely, Full Standards, Half Standards, and Dwarf Standards; fruit-trees particularly, being occaſionally trained in all theſe ways; but foreſt and tall ornamental trees rarely in any other than Full Standards; though in the ſhrub tribe they are occaſionally formed both into half and Dwarf Standards, according to their natural ſtature of growth. See each as below.

### Full Standards.

Full Standards.—Theſe are ſuch trees that are trained with tall, ſtraight, clean ſtems, ſix or ſeven feet high or more, clear of branches, then ſuffered to branch out at that height all around to form a head, as in common Standard apples, and pear-trees, foreſt-trees, &c.

All trees deſigned as Full Standards, ſhould be trained accordingly in their minor ſtate, by trimming off all lower laterals gradually as the ſtem advances in height, to encourage a clean ſtraight growth to the proper height, and promote the aſpiring of the top or leading ſhoot more expeditiouſly; ſuffering the leader always to remain entire, eſpecially in all foreſt-trees; or if it ſhould happen to fork, take off the worſt, and leave the ſtraighteſt ſhoot to run up, to continue the prolongation of the ſtem; and having thus run them up with clean ſtems ſix or ſeven feet, ſuffer them at that height to branch out into a head, and run in height as faſt as poſſible; though in fruit-trees the ſtem is often topped at ſix or ſeven feet height, to force out a ſet of laterals in that part, to form a regular ſpreading head of but moderate height, for the greater convenience of gathering the fruit: however, for all kinds of foreſt-tree Standards never reduce the top, but permit the leader to remain ever entire to run up in height; for the beauty and worth of ſuch trees conſiſts in their lofty ſtature.

However in ſeveral foreſt and ornamental Standards of the evergreen-tribe, the trimming their ſtems from laterals while young, as above, muſt be but ſparingly practiſed; ſuch as the pines, firs, cedars, and ſeveral others of the coniferous tribe, which being all of a reſinous nature, do not ſucceed if too cloſe pruned; ſo in training all theſe ſorts of ſtandards, trim only any lower ſtragglers occaſionally. Beſides, the diſpoſition of the branches of theſe ſorts covering the ſtem in circular rays to the very bottom, is thought additionally ornamental in their growth.

Almoſt all ſorts of fruit-trees may be trained for full Standards, except vines, though all ſorts will not ripen their fruit on Standards in this country; ſuch as peach, nectarines, apricots, and figs; on the other hand, all ſorts of apples, pears, plums, and cherries, ripen their fruit freely on Standards.

All fruit-trees deſigned as full Standards, are raiſed by grafting, &c on the freeſt ſtrong-ſhooting ſtocks, and trained with ſtraight clean ſtems full five or ſix feet high, either the ſtock trained up to that ſtature, and ſo grafted or budded at the deſired height, and the graft or bud branching out forms the head; or the ſtock may be grafted, &c. near the ground, and the firſt ſhoot from the graft or bud, trained up for a ſtem to the height aforeſaid; then ſuffered to ſend forth branches: obſerving in either method, it is next to be conſidered whether you intend the tree ſhall form a ſpreading open head, or aſſume a more erect and aſpiring growth; in the former caſe, if you top the leading ſhoot of the graft or bud, at ſix or ſeven feet from the ground, it will force out lateral ſhoots at that height, and commence a ſpreading head open in the middle, ſuffering however, the whole afterwards to take their own growth; and in the ſecond inſtance, that by permitting the leading ſhoot to remain entire, it will aſpire in height, and the whole head will aſſume a more upright and lofty ſtature; in both methods the heads will afterwards naturally branch out abundantly, and furniſh themſelves ſufficiently with bearing wood, producing fruit in two or three years from the grafting and budding; ſuffering them generally to take their own growth without ſhortening, and but very little other pruning, except the regulating any very irregular or bad growths, as below.

It being expedient to train moſt of our principal hardy fruit-trees as full Standards, as that when planted in continued rows, either in gardens or orchards, by having tall ſtems elevating the head conſiderably from the ground, it both admits the influence of the ſun and air more freely to the head all around; and admits of obtaining crops of eſculents,

eſculents, graſs, &c. on the ground, under their ſpreading branches.

With reſpect to the general culture of full Standard fruit-trees, in regard to pruning, &c. very little is required after the firſt training, to form the ſtem to the proper height, and the firſt ſhoots advanced at top to give the head its firſt formation; they ſhould afterwards generally be allowed to take their own growth, except reducing any very irregular growths, &c not ſhortening the general branches, but permit the whole to ſhoot both in length and branch laterally in their own way; and they will thus all naturally form fruit ſpurs all along their ſides upward for bearing; remarking, however, when any very irregular growing branch occaſionally occurs, it ſhould be retrenched; alſo if the head is much crowded, ſome ſhould be judiciouſly thinned out to keep the middle open, long ramblers reduced, and all ſuckers from the root, ſtem, and middle of the head, cleared away, and all dead wood; which occaſional prunings may be performed any time in winter.—See the culture of different fruit-trees, as apples, pears, plums, cherries, &c. under their proper heads; alſo PRUNING.

But ſometimes Full Standard fruit-trees are alſo planted againſt walls, and trained as wall trees; this being frequently practiſed for high walls, as the Standards having tall ſtems elevating the head ſix or eight feet, ſo as immediately to cover the upper part of the wall, whilſt dwarfs and Half Standards cover the bottom and middle part, and thus may every part of the wall be fully occupied at once; but the dwarf-trees being deſigned as the principal reſidents, that after they begin to advance conſiderably, and the Standards having borne a few years, the latter have their under branches gradually reduced to make room for the dwarfs, and at laſt are either wholly tranſplanted or deſtroyed, leaving the dwarfs in entire poſſeſſion of the wall, covering it effectually from bottom to top with their branches. See the different ſorts of wall-trees, as peaches, nectarines, apricots, &c. — Alſo the article WALL-TREES.

### HALF STANDARDS.

Half Standards.—Theſe are trees trained with ſhort ſtems only three or four feet high, then ſuffered to branch out at that height to form heads; being practiſed for many ſorts of fruit-trees, ſometimes both as detached Standards by way of variety, and by having low heads the fruit is more eaſily gathered; and likewiſe are often deſigned as wall-trees for high walls; that, as obſerved of the full Standards, they may cover the middle or upper part of the wall, whilſt dwarfs occupy the lower part.

As to the method of raiſing theſe Half-Standard fruit-trees, it is nearly the ſame as obſerved for the Full Standards only, they being grafted, or budded upon lower ſtocks, training them with upright ſingle ſtems only three or four feet high, either the ſtocks on which they are to be grafted trained up to that height for a ſtem; or being grafted or budded low in the ſtock, and the firſt main ſhoot of the graft, &c. led up for a ſtem, and ſo top it at the aforeſaid height to force out branches to form the head; ſuffering the head in all thoſe deſigned as detached Standards to branch out all around, and permitted to run up to a full ſpread, nearly according to their natural mode of growth, except juſt reforming any ill-growing branch, as hereafter noticed; for ſhortening the branches ſhould be very ſparingly practiſed, which would force out numerous uſeleſs ſhoots, and prevent the formation of bearing wood, eſpecially in the apple, pear, plum, and cherry kinds; remarking thoſe intended for walls ſhould have the head trained in a ſomewhat fanned manner, to ſpread to the wall like a common wall-tree; and as to the after-pruning, the ſame is to be obſerved as hinted in the general culture of the reſpective ſorts under their proper genera, whether in detached Standard or againſt walls.

It may ſometimes be proper to have theſe Half Standards ſo trained as to form heads of as moderate growth as poſſible, eſpecially the detached Standards, when deſigned for ſmall compartments; in which caſe they are grafted or budded upon the more dwarfiſh ſort of ſtocks, as apples upon codlins, and pears upon quinces, and ſo of other fruits; in which the head will always ſhoot moderate, and never ramble wide or grow high. See STOCKS.

But although a few Half Standard fruit-trees may be eligible as detached Standards for variety, they are not proper for any general plantation in the open quarters of the garden; becauſe their branches coming out low may impede the growth of under-crops; may however have a range thinly planted along the boundary or diviſion of any wide compartment, and their heads

ſuffered to run as hinted for the Full Standards.

For walls however that are eight or nine feet high, it is very proper to have a ſufficiency of Half Standards to plant between the dwarfs or principal reſidents, to cover the middle or upper half of the wall, whilſt the dwarfs occupy the lower ſpace, as remarked of the full Standards.—See WALL-TREES.

Half Standard fruit-trees are alſo proper to plant in forcing frames to produce early fruit. See FORCING FRAMES.

The culture of detached Half Standards, in reſpect to pruning, is nearly as the Full Standards; that having ſhot out at top to form the head, permit them to branch away both in length and laterally nearly in their own way, except juſt reducing any conſiderable irregularity, crowding branches in the middle, long ramblers, and all ſuckers from the root, ſtem, and head, and all dead wood; and thus the regular branches remaining at length, will emit fruit-ſpurs abundantly in every part for bearing.

And as to the Half Standards againſt walls, they are to be pruned and managed as other wall-trees, each according to its nature, as directed under their proper heads.

Foreſt-trees, and the taller ornamental tree kinds, are rarely ever trained as Half Standards, but moſtly always ſuffered to run up in height to their full ſtature, unleſs any particular ſort may be required to form buſhy Half Standards for ſome particular purpoſe; in which caſe if topped at three, four, or five feet height, it will branch out into a buſhy head.

Many of the ſhrub kind in their natural growth aſſume the appearance of Half Standards, though ſome are often branchy to the very bottom, or riſe with ſeveral ſtems; but might readily be trained with a ſingle clear ſtem, three or four feet high, and then ſuffered to branch out into a full head.

### DWARF STANDARDS.

Dwarf Standards.—They are trained with low ſtems only one or two feet high, being then topped to force out branches at that height to form the head.

Formerly ſeveral ſorts of choice fruit-trees were trained as Dwarf Standards, with ſtems ſeldom more than one foot high branching out at that height, forming proportionably low heads; being generally planted round the great quarters of the kitchen-garden, &c. inſtead of eſpaliers, and the heads kept down low by cloſe pruning, whereby they never produced much fruit; they however greatly prevailed in ancient gardening, and conſiſted of three ſorts.—Concave dwarfs, having the middle of the head hollow or concave. —Convex dwarfs having the head full from the middle all round —Horizontal dwarfs, having all the branches extended all round, in a flat or horizontal poſition; but the concave dwarf was in moſt eſteem; all of which Dwarf Standards being raiſed by grafting, &c. upon the moſt dwarfiſh ſtocks, ſuch as apples on paradiſe ſtocks, and pears on quinces, &c. in order to dwarf them as much as poſſible in their growth (ſee STOCKS); and as they ſhot in height, each year's ſhoots were generally pruned ſhort; and to keep the head down, and confine it within a ſmall compaſs; but by this ſevere pruning, they were forced into numerous uſeleſs ſhoots annually, and ſeldom formed a ſufficiency of bearing wood; ſo that they never anſwered the end effectually; and their branches growing ſo low, no ſmall crops could be obtained on the ground under them, on which conſideration they are become in diſrepute, eſpecially ſince eſpaliers have been brought to ſuch perfection. — See DWARF TREES and ESPALIERS.

However, for the ſake of variety and curioſity, a few Dwarf Standards of all ſorts of fruit-trees might be admitted, one here and there, and by a judicious moderate pruning, according to their nature as directed for the reſpective ſorts under their proper heads, and the article DWARF TREES, they will bear abundantly in proportion to their ſize.

Likewiſe may have ſome Dwarf Standard fruit-trees in pots, for the purpoſe of forcing in hot-houſes, forcing-frames, hot-beds, &c. particularly early May, and May duke-cherries, nutmeg-peaches, maſculine apricots, figs, vines, gooſeberries, currants, &c. which being placed in the above departments at the proper ſeaſon, i. e. January or early in February; they will often ripen a few fruit very early in tolerable perfection, which might be brought to table growing on the trees in the pots. But dwarf Standard fruit are alſo proper to plant fully in the borders in forcing frames. See FORCING-FRAME.

For the particular method of raiſing and training the different ſorts of theſe Dwarf Standards. See DWARF TREES.

Numbers of the upright ſhrub tribe naturally form themſelves of the Dwarf Standard kind,

kind, as riſing with low, erect, firm ſtems, perhaps but half a foot, or a foot or two high, branching out near the ground into buſhy heads, ſuch as the gooſeberry, currant, and numerous flowering ſhrubs and evergreens; though great numbers of the ſhrub kind are apt to riſe with ſeveral ſtems immediately from or near the root, forming a buſhy growth quite from the bottom, which in many caſes in the ſhrubbery way may be allowable; in others, it may be proper to train them with one ſtem, which is eaſily effected by retrenching the ſuperfluities and trimming away low ſtragglers, forming a clear ſingle ſtem half a foot, or a foot or two high, according to their nature, then ſuffered to branch out into a full head.

For many of the low Standard flowering ſhrubs and evergreens appear to the beſt advantage, when trained as Standards to a ſingle ſtem a foot or two high, terminated by a branchy full head.

Likewiſe, all the fructiferous ſhrubs, ſuch as all the varieties of currants and gooſeberries, ſhould generally be trained with a ſingle ſtem a foot or more high, then permitted to branch out at that height into a regular head, keeping the internal part always tolerably open, and the branches moderately thin, and ſhorten them but ſparingly, particularly the goooſeberry.—See RIBES.

STAPHYLÆA, Bladder-nut.

Two hardy deciduous flowering ſhrubs compoſe this genus, both of which are proper furniture for the ſhrubbery, being of largiſh upright growth, generally obtaining eight or ten feet ſtature, adorned with pinnated and ternate five, and three-lobed leaves; and long ſlender bunches of pentapetalous flowers, ſucceeded by bladder-like capſules; whence the name Bladder-nut.

Claſs and order, *Pentandria Trigynia.*

*Characters.*] CALIX, is roundiſh, concave, coloured, and almoſt as large as the corolla. —COROLLA, five oblong erect petals, nearly like the calix, and a pitcher ſhaped nectarium at the bottom.—STAMINA, five oblong erect filaments, crowned with ſimple antheræ. — PISTILLUM, a thick three-parted germen, and three ſtyles, having obtuſe ſtigmas contiguous.—PERICARPIUM, three inflated ſhaped-ſhaped capſules, joined together by a longitudinal ſuture or ſeam, having acuminated tops, and open inwardly, incloſing two almoſt globular, hard, nut-like ſeeds.

There are only two ſpecies, both very hardy deciduous ſhrubs, the firſt of which is a native of England and other parts of Europe, the other is from America; are diſtinguiſhed by the names of five-leaved, and three-leaved Bladder-nut.

The ſpecies are,

[1]STAPHYLÆA *Pinnata.*

*Pinnated five-lobed European Bladder-nut.*—Riſes with upright, ſhrubby, ſmooth, browniſh ſtems, branching eight or ten feet high or more, with very pithy ſhoots; garniſhed with pinnated leaves of two pair of large, oblong, oval lobes, and an odd one; and at the axillas along the ſides of the branches, long pendulous bunches of white flowers, ſucceeded by large, inflated, or ſwoln, bladder-ſhaped capſules, containing roundiſh hard ſeeds or nuts ripening in autumn.

This ſort grows wild in England, and many other parts of Europe; and is cultivated in gardens to encreaſe the variety, in ornamental plantations, where it flowers and ripens ſeed annually.

The ſeeds or nuts are in ſome countries eaten, but have a very unpalatable reliſh.

[2]STAPHYLÆA *trifoliata.*

*Trifoliate or Three-leaved Virginia Bladder-nut.*] Riſes with upright, ſhrubby, ſmooth, greyiſh ſtems, branching eight or ten feet high; garniſhed with ternate or trifoliate leaves, being compoſed each of three large oval lobes; and at the ſides of the branches, long, hanging bunches of white flowers, ſucceeded by large inflated capſules, containing roundiſh hard ſeeds, ripe in autumn.

Both the ſpecies flower annually in May, numerouſly in pendulous bunches, each flower having five oblong petals; and the ſeeds ripen in autumn, proper to ſow for propagation.

Theſe ſhrubs are very eligible furniture for diverſifying any of the hardy ornamental deciduous plantations, but particularly the larger ſhrubbery compartments, where being planted in aſſemblage with other ſhrubs, principally of the deciduous tribe, they will agreeably multiply the variety with their pentaphyllous and ternate foliage, long pendulous bunches of flowers, and bladder-ſhaped capſules, which exhibit a ſingular appearance in autumn.

*Method*

*Method of Propogation.*

The propagation of both theſe ſhrubs is moſt eaſily accompliſhed by three or four different methods, viz. by ſeed, ſuckers, layers, and cuttings.

By Seed.—This ripens plenteouſly in autumn, when it ſhould be ſowed ſoon after it is ripe, in a bed or border of any common earth, either in drills or promiſcuouſly on the ſurface, covering them near an inch deep; and being thus ſowed early in autumn, they will come up the following ſpring, though probably not all of them till that time twelvemonth, keeping them clean from weeds; and, if in the early part of ſummer, very dry weather prevails, refreſh them with frequent waterings, repeating thoſe operations during ſummer as occaſion may require; and by autumn or ſpring following, the largeſt plants will be fit to plant out in nurſery-rows, or at leaſt in the ſecond autumn they may be wholly planted out, placing them in rows two feet aſunder, and one foot diſtance in each row; here to have two or three years growth, or till wanted for the ſhrubbery, &c.

By Suckers.—The plants of a few year's ſtanding generally ſend up ſuckers from the bottom in tolerable plenty, which may be eaſily taken up in autumn or winter with roots, and planted in nurſery-lines, to have one or two years growth, then tranſplanted into the ſhrubbery, when required.

By Layers.—In autumn or winter chuſing the younger branches, lay them either by ſlit or twiſt-laying (ſee LAYERS), and they will be properly rooted by the following autumn; when they ſhould be planted off in nurſery-rows for a year or two, to gain due ſtrength for the ſhrubbery.

By Cuttings.—In October or November procure a quantity of young ſhoots of the former ſummer's growth, chuſing principally the lower part of the ſhoots; plant them in a ſhady border, giving occaſional waterings the following ſpring and ſummer in dry weather, and they will be moſtly well rooted by the following autumn.

STATICE, Thrift or Sea Pink, and Sea Lavender.

Conſiſts of low, hardy, herbaceous, and under-ſhrubby plants for ornament and variety; ſome of which being flowery perennials are employed in the decoration of the pleaſure ground; they riſing, ſome ſorts with very low, cloſe, tufty heads, of numerous, ſmall, narrow, graſſy, evergreen leaves cloſe to the earth, and very ſlender ſingle flower-ſtalks but half a foot, or a little more or leſs high; others having much larger, broad, radical leaves, and ſtronger ſtalks dividing into branches; all the ſtalks and branches of the ſorts in general terminated with globular and ſpiked aggregate heads, of numerous ſmall, infundibuliforme, pentapetalous flowers.

Claſs and order, *Pentandria Pentagynia.*

*Characters.*] CALIX, an aggregate of florets collected into globular or ſpiked heads, included wholly in one common cup of divers ſtructures in the different ſpecies, each floret having alſo its proper calix, which is monophyllous and funnel-ſhaped.—COROLLA, is funnel ſhaped, conſiſting of five ſmall petals, narrow at the baſe; but broad, obtuſe, and ſpreading above.—STAMINA, five ſubulate filaments that adhere to the ungues or claws of the petals, and incumbent antheræ.—PISTILLUM, a ſmall germen, and five ſiliform diſtant ſtyles, crowned with acute ſtigmas. PERICARPIUM none, the ſeeds one in each floret, are lodged in the general calix, each ſeed coronated by its own proper cup.

Since to this genus has been added the *Limonium* or Sea Lavender, the ſpecies are multiplied to fourteen in number; the firſt of which is the common Thrift or Sea Pink, a ſmall hardy herbaceous evergreen, well known to all for its uſe, occaſionally as an edging to borders, &c. comprehends ſeveral varietes, all very low, cloſe-growing, graſſy-leaved plants: the other thirteen ſpecies, being moſtly of the Sea Lavender kinds, are of larger growth, with broadiſh leaves; and conſiſt of herbaceous and under-ſhrubby perennials and annuals; but not poſſeſſing any great merit for general garden culture, are not much attended to; ſo that only one ſpecies, common Thrift, and varieties above hinted, are commonly cultivated: however, ſome of the moſt material of the Sea Lavender kinds, as below, may alſo be introduced for variety where large collections are required.

*Common Thrift Kinds.*

One ſpecies only comes under this head, compriſing however ſeveral varieties; ſome of which were formerly conſidered as diſtinct ſpecies,

ſpecies, but prove all varieties only of *Statice Armaria*, or common Thrift, differing ſomewhat in their ſize and colour of the flowers, as noticed below.

[1]STATICE *Armeria.*

*Armeria, Common Thrift or Sea Pink.*] Hath a thick, fibrated, ſpreading, perennial root, dividing into heads at top, cloſely crowned with thick tufty heads of numerous linear, graſſy, evergreen leaves cloſe to the ground; and among them numerous ſlender ſingle ſtalks, from five or ſix to eight or ten inches or more; each crowned with a globular aggregate of red and other coloured flowers in the varieties, appearing in June and July.

*Varieties.*] Common ſmaller Thrift with pale-red flowers.—With ſcarlet flowers, and with white flowers.—Greater Thrift with red flowers.—Greater Thrift with white flowers.—Leaſt Sea Pink with ſmall fleſh-coloured flowers.—All of which flower profuſely from the end of May until July or Auguſt.

Remarking, as to the difference in ſize and growth of theſe varieties.—The common ſmaller Thrift is diſtinguiſhed by its leaves being more narrow, graſſy, and of lower growth, and the flower ſtalks only five or ſix inches high, being the ſort moſt commonly uſed for edgings; the greater Thrift having longer and broader leaves, and flower-ſtalks near a foot high; and the leaſt Thrift have exceeding narrow, ſhort leaves, flower-ſtalks only three or four inches high, and very ſmall heads of flowers.

All the ſorts are inhabitants of plains and meadows, chiefly near the ſea in moſt countries in Europe and North America; but have been long admitted into gardens as flowery plants, and were formerly in great eſtimation to plant for edgings to beds and borders, as being of very low cloſe growth, and always green: and alſo to plant in tufts about the flower-borders and other compartments of the pleaſure ground, as they ſucceed in any ſoil and ſituation, and flower very abundantly in June and July, making a good ornamental appearance, more particularly the red and ſcarlet ſorts; but they make the grandeſt ſhow when diſpoſed in long cloſe ranges, either in ſingle rows, as edgings to borders along the ſides of the walks, or in one or more ranges together, extended lengthways, of any bed or border in ſome conſpicuous ſituation; and for all of which purpoſes they are very expeditiouſly raiſed by ſlipping the heads and roots at almoſt any ſeaſon, but principally in autumn and ſpring.—See their *Propagation.*

However, for edgings in particular is the principal merit of theſe plants, and as they grow very cloſe, low, and continue in verdure all the year, they form the moſt uſeful and eligible edging, next to box; and in ſome caſes, in rural works particularly, are ſometimes preferred to box edgings, eſpecially as they flower very ornamentally for two months in ſummer; but are not however ſo proper for general uſe; as being rather apt to ſpread ſoon out of bounds and require to be reduced, either by cutting it inconſiderably on each ſide, or by taking it up and replanting it afreſh every two or three years.—See EDGINGS.

*Sea Lavender Kinds.*

Theſe ſorts aſſume a different appearance from the common Thrift kinds, both in their foliage and mode of flowering; their leaves not being ſo ſmall and graſſy, but moſtly plane and broadiſh, and the ſtalks generally dividing into panicles terminated by the flowers, not in globular heads like the Thrift, but chiefly in ſpiked aggregates; but their general *characters* proving the ſame as in the Thrift, they are all conſidered as true ſpecies of *Statice.*

[2]STATICE *Limonium.*

*Limonium, or Sea Lavender.*] Hath thick, reddiſh, fibrated roots, crowned with oval, ſpear-ſhaped, ſmooth leaves; and upright, firm, taper, naked ſtalks a foot or more high, dividing into paniculated branches, all terminated by ſpiked heads of pale-blue flowers, in July and Auguſt.

*Varieties.*]—Common great Sea Lavender.—Narbonne great late-flowering Sea Lavender.—Olive-leaved Sea Lavender.—Deep blue-flowered Sea Lavender.—White flowered Sea Lavender.

This ſpecies grows naturally on the ſea-ſhores of England, &c. and is ſometimes retained in the gardens for variety.

[3]STATICE *Tartarica.*

*Tartarean Sea Lavender.*] Hath long, ſpear-ſhaped, ſharp-pointed leaves; and forked, branchy, ſpreading ſtalks ſix or eight inches high, terminated by ſpiked heads of whitiſh alternate flowers at a diſtance, in Auguſt and September.

[4]STATICE *Reticulatum.*

*Netted Sea Lavender.*] Hath cuneiform or wedge-ſhaped lower leaves; proſtrate ſlender ſtalks, and retroflexed naked ſterile branches netted or matted together; and the ſtalks terminated by panicles of pale blue flowers, in July and Auguſt.

This is a ſea-ſide plant of England, and moſt parts of Europe.

[5]STATICE *Cordata.*

*Cordated or Heart-leaved Mediterranean Sea Lavender.*] Hath thick, ſpatulate, heart-ſhaped, retuſe, ſmooth leaves cloſe to the ground; and ſlender naked ſtalks ſix inches high, terminating in panicles of pale red flowers, in Auguſt.

[6]STATICE *Flexuoſa.*

*Flexuoſe Siberian Sea Lavender.*] — Hath oval nervous leaves from the roots; and weak, flexuoſe, branchy ſtalks eight or ten inches long, terminated by corymbus bunches of flowers, in Auguſt and September.

[7]STATICE *Suffruticoſa.*

*Under-ſhrubby Siberian Sea Lavender.*] Hath under-ſhrubby ſtalks, naked and branching near the top, riſing near two feet high; ſpear-ſhaped variegated leaves; and cloſe-ſitting round heads of pale-blue or whitiſh flowers, in Auguſt and September.

All theſe ſeven ſpecies, both of the Thrift and Sea Lavender kinds, are very hardy fibrous-rooted perennials, ſix of them being herbaceous, and the ſeventh is under-ſhrubby; all of which flower abundantly in ſummer, but not all very ornamentally; the flowers are numerous, but ſeparately ſmall; and are univerſally funnel-ſhaped, and pentapetalous; and many collected together into aggregates, within one general cup (ſee the *characters*); being generally produced at the ends of the ſtalks and branches, in ſome ſingly, in others in panicles as before deſcribed in each ſpecies; but are not all commonly ſucceeded by ſeeds in the gardens.

The firſt ſpecies, *Statice Armeria*, and varieties, being conſiderably the moſt material, both for their uſe as edgings, and flowering plants, are almoſt the only ſpecies of this genus that is generally cultivated.

The other ſix ſpecies are at preſent not common in the gardens, except in thoſe of ſome curious botaniſts for obſervation and variety; however, all the ſorts of them that can be obtained, may with propriety be admitted, to encreaſe the variety, as they take up but little room, will grow in almoſt any common ſoil and ſituation, though if but moderately expoſed to the ſun, they will probably be the more ſucceſsful and durable.

All the ſorts, both the Thriſt and other kinds, may be planted any time in autumn or ſpring.

The Thriſt kinds, as we before noticed, are proper both to form edgings, and to plant in detached tufts about the borders: the ſcarlet Thrift is the moſt beautiful in regard to its flowering, but for variety ſhould alſo admit the pale-reds, and white kinds, all of which ſucceed almoſt any where, and may be planted at almoſt any ſeaſon when not in flower; though the autumn and ſpring are the moſt ſucceſsful ſeaſons for planting them.

As to the method of planting Thrift edgings, a quantity of ſlips being obtained in the ſeaſons above-mentioned from old plants, by ſlipping or dividing the off-ſets of their roots, not however too ſmall, and each ſlip furniſhed with roots and top; then having made up the edge of the bed or border even and firm, proceed to plant them with a dibble in one range, two or three inches diſtance in the row; or to form at once a cloſe edging, may plant them ſo near as to touch one another; and ſome, to perform this more effectually, form a ſmall trench, as in planting box edgings; ſo plant the Thrift in the trenches quite cloſe together, to form immediately a compact uniform edging, in the manner of a box-edging aforeſaid. See BUXUS, SUFFRUTICOSA, and EDGINGS.

And as to the culture of theſe edgings, they ſhould every ſummer immediately after flowering, be trimmed with garden-ſhears or the like, to cut off all the decayed flower-ſtalks cloſe to the bottom; likewiſe, to trim in any projecting irregularity of the edging at ſides or top: alſo when it ſpreads conſiderably out of bounds, ſhould be cut in evenly on each ſide, in due proportion; obſerving to perform thoſe occaſional trimmings generally in moiſt weather, and not too late in autumn, otherwiſe the drought of ſummer, or the cold in winter may injure it when newly cut, and cauſe it to aſſume a ſhabby diſagreeable appearance.

Obſerve however, that when theſe edgings grow conſiderably out of bounds, or become very irregular, it is proper to take them up,

ſlip

ſlip the plants ſmall, and immediately replant them again as before, in a neat regular edging.

Sometimes theſe edgings require replanting, as above, every two or three years.

*Method of propagating all the Species.*

All the ſorts are very eaſily propagated, by ſlipping or parting the roots, in autumn and ſpring.

Thriſt kinds.—All the varieties of Thriſt propagate abundantly by off-ſets of the root and head; which in early autumn, or in the ſpring, &c. may either be ſlipped off from any growing plants, or any large old plants taken up and wholly divided, each into as many ſeparate ſlips, as it admits preſerving the root and top to each ſlip; and plant them directly, either in an edging or where wanted.

Sea Lavender kinds.—They may be propagated by parting their roots, in autumn or ſpring: alſo ſome of them by ſlips or cuttings of their ſhoots in ſummer, planted in a ſhady border, or ſhaded and watered, and they will be rooted by autumn.

Theſe ſorts may alſo be raiſed from ſeeds when they can be obtained from the places where they ripen, in England and abroad; ſowing them in autumn, or early in ſpring on an eaſt border, and in warm dry weather give frequent waterings, both before and after the plants come up; and in autumn plant them out.

STELLATA, or Starry Plants.

Such as have their leaves diſpoſed in rays or whirls round the ſtem at intervals, and point different ways like the figure of a radiant ſtar; exemplified in *Rubia tinctorum*, or common madder, &c.

STEWARTIA, *Stewartia.*

There is but one ſpecies, a hardy deciduous flowering ſhrub from North America, proper for the ſhrubbery compartments, riſing ſeveral feet high, adorned with largiſh ſimple leaves, and large pentapetalous flowers.

Claſs and order, *Monadelphia Polyandria.*

*Characters.*] CALIX, is monophyllous, divided into five oval-ſpreading ſegments, and permanent.—COROLLA, five large oval, ſpreading petals.—STAMINA, many filiform monadelphous filaments, being united into a cylinder at bottom, connected to the petals at their baſe, and crowned with roundiſh incumbent antheræ.—PISTILLUM, a roundiſh hairy germen, five ſlender ſtyles, having obtuſe ſtigmas.—PERICARPIUM, a quinquelobate pomaceous capſule of five cells, each having an oval compreſſed ſeed.

STEWARTIA *Malacodendron.*

*Stewartia* or *Malacodendron.*] Riſes with a ſhrubby ſtem branching irregularly on every ſide, eight or ten feet high, having the branches covered with a browniſh bark; oval, ſpear-ſhaped, ſawed, veined, alternate leaves, two or three inches long, and half as broad; and at the ſides of the branches large white flowers, having numerous purple ſtamina ſurrounding the five ſtyles; flowering early in June, but do not perfect ſeeds in England.

This elegant ſhrub is a native of Virginia, from which country it was introduced into our gardens to encreaſe the variety in the ſhrubbery collection; though it is not as yet near ſo plentiful here as many other American ſhrubs; but is raiſed in moſt of the nurſeries for ſale.

It is a hardy ſhrub, though young ſeedling plants of it are rather a little tender, the firſt year or two requiring ſhelter from froſt, but after having acquired more ſtrength, will ſtand very well in the open ſhrubbery the year round.

It is propagated by ſeed and by layers, and ſometimes by cuttings.

By Seed.—This the ſeedſmen procure annually from abroad; ſow it as ſoon as poſſible in pots of light earth half an inch deep, and plunge them in a hot-bed, either of dung or bark, under glaſſes, giving occaſional waterings, and moderate ſhade from the ſun, both before and after the plants come up; being careful to harden them gradually in due time to the open air in ſummer; but in winter place them under a garden-frame, to remain till ſpring; when, in order to forward them as much as poſſible, may plunge them again in a bark-bed for a month or two, till towards ſummer, then gradually hardened, and plunged in a ſhady border till autumn, at which time removed again under ſhelter all winter; and in March following, may pot them off ſeparately into ſmall pots plunging them alſo in a bark bed to ſtrike them more expeditiouſly, beſtowing proper waterings and occaſional ſhade; not forgetting to harden them as before, and indulge them with ſhelter another winter or two; and in ſpring following, when the weather is ſettled,

may venture to turn them with the balls of earth about their roots into the full ground.

By Layers.—Chuſe the young ſhoots for laying, which may be performed early in autumn, generally by ſlit-laying; and in the following ſpring and ſummer in dry weather, do not fail to give frequent waterings; and if indulged with a moderate ſhade in the heat of ſummer, they will root more freely, which they ſometimes effect in one year, when in March pot them off ſeparately; and if then plunged in a bark-bed, or in any moderate heat for a few weeks, will forward them conſiderably; removing them to a ſhady border all ſummer, to ſhelter of a frame in winter; and in ſpring after, tranſplant them with balls into the open ground, finally to remain.

By Cuttings.—Young ſhoots in ſpring and ſummer being planted in pots of good earth, and plunged in a bark-bed, ſome of them will probably ſtrike and commence proper plants, which muſt be timely inured to the open air, and managed as the ſeedlings and layers.

STIGMA of the flower,

Is the extremity or ſummit of the piſtillum, or female organs of flowers.

The Stigma forms the head or ſummit of the ſtyle, and is accounted the principal female organ of plants, deſigned for the reception of the farina or fecundatory duſt of the antheræ or male organs, which being diſcharged upon the moiſt Stigma, the particles burſt, and ſhed their fertilizing ſeminal virtue; and being abſorbed by the Stigmata, its effluvia or eſſence is tranſmitted through the ſtyle or vagina, into the heart of the germen, ovary, or ſeed-bud, for the purpoſe of impregnating the ſeeds.—See PISTILLUM, FILAMENTUM, and STYLUS.

As to figure, the Stigma is various in different plants; it being in ſome formed into a round or globular head; in others, it is either oval, orbicular, angular, crown-ſhaped, target-ſhaped, croſs-ſhaped, ſtump-ſhaped, hook-ſhaped, petal-ſhaped (as in *Iris*), obtuſe, depreſſed, concave, channelled, ribbed, ſtreaked, feathered, hairy, downy, &c.

In reſpect to number, the Stigma is either ſingle or but one, as in the generality of flowers; bifid or two, as in lilac; three, as in *campanula*; four, as in *epilobium* or French willow-herb; five, as in ſome plants.

With regard to ſituation, the Stigma generally terminates or crowns the ſtyle, as in moſt plants; ſometimes when there are many Stigmata, they are diſpoſed with admirable ſymmetry along the ſides of the ſtyle; and when the ſtyle is wanting, as in poppy and ſome other flowers, the Stigma reſts immediately on the germen or ſeed-bud.

In general, the ſurface of the Stigma is covered with a viſcous or clammy moiſture, ſerving to attract, retain, and diſſolve the particles of the fecundating powder, and thereby more eaſily tranſmit its effluvia to the ſeeds below.

For in the vegetable kingdom the genital duſt of the antheræ being carried by the air to the moiſt Stigmata, where the particles burſt, as before obſerved, and diſcharge their exceeding fine or ſubtle contents, and impregnate the ovary; as is often obvious to ſight in many plants when in flower, and the farina flying about, that part thereof lights upon and clings to the Stigma; which ſome flowers ſhew in a moſt agreeable manner, ſuch as in the panſies, that when the flower is ſcarcely opened, we ſhall ſee the Stigma like a concave globe gaping open on one ſide, and of a pure white colour; but as ſoon as the antheræ of the five ſtamina have diſcharged their genital male duſt, you may obſerve the whole Stigma filled with this duſt, or fertilizing powder, and covered all over with a yellowiſh-brown colour.

With reſpect to duration, the Stigma moſt commonly withers after the impregnation is effected, except in ſome few genera, ſuch as poppy and water-lily, &c. in which the Stigmata is permanent or abiding.

STIPULA of the leaves, &c.

Is a ſcale or very ſmall leaf on each ſide the baſe of the foot-ſtalk of ſome leaves and flowers.

Theſe Stipula are defined to be one of the *fulcra* or props of plants, deſigned to ſupport more firmly the bud of the leaf, &c. on which they are attendant, as they are generally ſtationed one on each ſide; though ſome plants have only one, and a great many none at all; they are however common to a great number of plants, both trees and herbaceous vegetables; their ſituation is moſtly on the outſide of the leaves, and in ſome few plants on the inſide; being of divers figures, and ſizes in different ſpecies; and in ſome plants they grow free, looſe, and detached; in others, they grow cloſe to the plant; in ſome plants they are deciduous or

fall

fall off before the leaves; others are permanent, continuing till the general fall of the leaf.

Thus the Stipula often afford excellent marks of diſtinction in diſcriminating the ſpecies; as from its ſituation, number, ſize, duration, &c. on the particular ſpecies, their difference is frequently more eſſentially diſtinguiſhed.

The Stipula is in many plants very diſtinguiſhable and conſpicuous, ſuch as in roſe, apricot, peach, caſſia, tamarind-tree, tulip-tree, bird-cherry, and all the papilionaceous or leguminous plants, and many others.

STOCKS, for Grafting and Budding.

Stocks, when alluding to the operation of grafting and budding, are young trees raiſed from ſeed, ſuckers, layers, and cuttings occaſionally, deſignedly for the reception of grafts or buds of other trees, of any ſelect or approved ſort, to propagate and continue them the ſame without variation, by their uniting with the ſaid young trees or Stocks, ſhoot out into branches, and become trees in all reſpects like the approved parent trees from which they were taken, and they thus remain ſupported and nouriſhed by the trees on which they are grafted, commonly termed Stocks.

For as numerous trees, particularly the varieties of certain ſpecies, not continuing the ſame from ſeed, but often vary exceedingly to very different ſorts, in order to continue them of the ſame approved varieties with certainty, recourſe is had to propagating them by the operation of grafting or budding, being the inſertion of ſhoots or buds of the ſaid approved kinds of trees into the Stock or ſtem, or even the branches of other trees, which when intended for the purpoſe of grafting, &c. are always denominated Stocks, and ſhould generally be ſpecies or varieties of the ſame genus as the trees with which they are to be grafted, or very nearly allied in their general *characters*, otherwiſe they will not grow upon one another: but the Stocks and grafts being of the ſame family, and the grafting and budding properly executed, the grafts, &c. unite firmly with the Stock, ſhoot and branch out into full heads, commencing trees in every reſpect like the ſelect kinds from which the grafts or bud were cut, producing ſhoots, leaves, flowers, fruit, and ſeed, exactly the ſame as the ſaid parent trees; whether fruit-trees, foreſt-trees, ſhrubs, &c. always retaining their reſpective properties diſtinct from the Stock, the Stock alſo continuing its inferior quality diſtinct from the graft, not interfering with the nature or quality of the trees grafted thereon; only ſupporting and nouriſhing them as effectually, as if upon their own roots; ſometimes however, particular ſorts of Stocks affect ſome varieties of trees, ſo far as to render them of longer or ſhorter duration; alſo in ſome ſorts of trees improve or diminiſh the quality of the fruit: ſo that it is of conſequence to be acquainted with the proper Stocks on which to graft or bud the different trees for general ſervice, not only the trees of different genera, but alſo thoſe of particular ſpecies, and varieties of each reſpective genus, as hinted hereafter in the general liſt of Stocks.

So that all trees, whether young or old, deſigned for grafting or budding upon, from the ſize of a large gooſe's quill, to one, two, or three inches in diameter, are diſtinguiſhed by the appellation of Stocks; becauſe the graft or bud is inſerted into the ſtock or ſtem, ſometimes occaſionally into the branches, when intended to renew any old fruit-tree, or change the ſort of fruit, or have two, three, or more ſorts of flowers, fruit, &c. on the ſame tree; in all of which caſes, the part receiving the graft or bud is ſtyled the Stock.

Remarking, that Stocks for general uſe, may be uſed as ſuch either for grafting or budding, when from the ſize of a good gooſe-quill, to half an inch, or not more than an inch thick in the part where the graft, &c. is to be inſerted; likewiſe Stocks of two, or three inches or more diameter, either the ſtems or branches are alſo occaſionally grafted or budded with ſucceſs, not proper however for general practice; for the ſmall young Stocks, of from two, to three or four years growth in the nurſery, &c. and from about a quarter to half an inch thick, or but a little more or leſs in the part to be grafted, whether dwarf or ſtandards, are generally the moſt ſucceſsful for general grafting or budding in the nurſery plantations, to raiſe any conſiderable quantity of trees for tranſplantation, either for private or public ſupply.

Ob-

Obſerving likewiſe, Stocks for grafting and budding, are employed both for moſt kinds of fruit-trees, ſome varieties of foreſt and ornamental trees, and many of the ſhrub kind occaſionally; as is generally exhibited in the culture of the reſpective ſorts in the proper genera.

Remark alſo, that Stocks almoſt in general, when intended for grafting and budding, ſhould be ſpecies or varieties of the ſame genus as the trees with which they are to be ingrafted; for moſt of the tree and ſhrub kind, whether fruit-trees, foreſt-trees, &c. ſucceed principally upon Stocks of their own family only, or ſuch that are very near kindred by the *characters* of their flowers; their being but very few inſtances in which trees of different genera will grow by grafting or budding upon one another, except in ſome ſimilar caſes as follow; for example, the peach, nectarine, and almond being all of the genus *Amygdalus*, will take upon one another; and on Stocks of the *prunus* or plum, generally ſucceeding beſt upon that kind of Stock; that though of two diſtinct genera, are all icoſandrious plants of the drupaceous ſtone-fruited tribe, nearly allied in their general *characters*; the ſame is alſo obſervable of the pear, which will take upon ſome ſpecies of the *Meſpilus* and *Sorbus*, alſo on ſome of the ſpecies of *Cratægus*, ſuch as white-thorn or haw-thorn Stocks; and all of thoſe upon one another: but neither of theſe, nor the pear, however, are equally ſucceſsful as upon Stocks of their own family; and even all the ſpecies of the ſame family do not ſucceed equally well upon one another, ſome ſorts requiring Stocks principally of their own ſpecies, others thoſe of ſome particular ſpecies or variety in the ſame genus.

For it being alſo remarkable, that although all the ſpecies of any particular genus grow by grafting or budding upon Stocks of one another, yet moſt ſorts ſucceed beſt upon their own Stocks, except in a few inſtances; for example, the apple, pear, and quince being three diſtinct ſpecies all of the genus *Pyrus*, and will take upon Stocks of one another as above obſerved, but improper for general practice, as the apple always ſucceeds beſt upon its own ſpecies, i. e. any kind of apple or crab Stocks raiſed from the kernels of the fruit; the pear upon pear Stocks raiſed in the ſame manner, and occaſionally upon quince Stocks to form dwarf-trees; and the quince grows free enough on their own, or pear Stocks; again, the plum, cherry, and apricot, being all ſpecies of the genus *prunus*, and the grafts and buds of all three ſpecies will grow upon Stocks of one another, yet not all equally proſperous; for the cherry is always the moſt thriving upon cherry ſtocks, and plums and apricots beſt upon plum Stocks.

And in ſeveral inſtances ſome ſorts are the moſt thriving on ſome particular variety of their reſpective favourite Stocks, exemplified in the peach and nectarine, which being generally more thriving and durable on plum Stocks than their own, yet on one particular variety of plum, namely the muſcle-plum-Stock, they are generally the moſt proſperous and durable; the ſame is alſo obſerved of ſome other trees, both fruit and foreſt-tree kinds, as hereafter hinted in the liſt of Stocks.

Likewiſe, ſome ſorts are the moſt proſperous on crab Stocks, others ſucceed well only on free Stocks, and ſome require dwarf Stocks, to dwarf them more or leſs, either for walls, eſpaliers, or forcing-frames, &c. See Crab Stocks, Free Stocks, &c. below deſcribed.

### *Of the different Kinds.*

For the various kinds of Stocks may for diſtinction ſake, be divided into three claſſes, agreeable to their different natures, viz. Crab Stocks, Free Stocks, and Dwarf Stocks; each of which comprehending various ſorts, both of the ſame and different genera, ſpecies, and varieties; and thoſe of each claſs, although they may prove ſpecies or varieties of the ſame genus, yet often aſſume different properties requiſite to be known previous to their being grafted or budded, as deſcribed below each under its own head.

Crab Stocks.—The ſort of Stocks generally conſidered as crabs, are all ſuch that are raiſed from ſeeds, &c. of any wild ungrafted trees, particularly of the fruit-tree kind; ſuch as the wild crab-apple of the woods and hedges, any kind of wild thorny uncultivated pears, plums, wild black and red cherry, and of ſuch other trees as have not been grafted or budded; and as to the merit of theſe wild

Crab

Crab Stocks, ſomeſorts being ſtrong ſhooters and hardy, are preferred, on which to graft ſome particular ſpecies, as ſuppoſed to improve the ſize and duration of the trees; for example, apples are very commonly worked upon the common wild Crab Stock, and cherries on the great wild black and red cherry Stock, as tending to promote a large, hardy, and durable growth proper for common ſtandards, and the larger kinds of dwarf trees; remarking however, in uſing Crab Stocks for general uſe, on which to graft any ſorts of fruit-trees, it is proper to reject ſuch of them as aſſume a very wild crab-like growth, or of a ſtunty, thorny nature, preferring thoſe that are the freeſt clean growers.

However, the appellation of Crab Stocks, is alſo often given to all Stocks indiſcriminately, before being grafted; whether raiſed from the ſeed, &c. of wild or cultivated trees, being very commonly all denominated crabs until worked with grafts or buds; though probably with ſome diſtinction, as wild crabs, and free crabs.

Free Stocks.—The name Free Stocks is commonly applied to ſuch as are raiſed from the kernels of the fruit, layers, &c. of any of the cultivated garden and orchard fruit-trees and others, which as they often prove in general more free clean ſhooters than the generality of wild crabs, have the appellation of Free Stocks, and in ſeveral inſtances when proving free clean growers, are more eligible Stocks than the wild crabs, particularly for choice pears, peaches, nectarines, apricots, and plums, both to improve the growth of the trees and quality of the fruit, as is obſerved below in the Liſt of Stocks, and in the culture of the reſpective ſorts under their proper head; obſerving however, that as alſo in theſe ſeedling Free Stocks, ſome may appear of a wild crab-like growth, or of a ſtunty thorny nature, as aforeſaid; which, when the real Free Stock is intended, ſhould be all eradicated, reſerving only the free clean ſhooters of a cultivated-like growth for grafting and budding.

But as we noticed above of the crab Stocks, all Stocks raiſed from ſeed particularly, both of the wild, and cultivated garden fruits, are before they are worked very commonly termed crabs; either wild crabs or free crabs, as before obſerved, and with ſome propriety; ſince all ſeedling Stocks though raiſed from the fineſt fruit, vary ſo greatly from the original, many of them often aſſuming a wild crab-like growth, and if permitted to ſtand long enough without grafting to bear, it is probable the fruit would prove alſo of the crab nature, intolerably hard and auſtere; hence the neceſſity of grafting and budding: but on the other hand, many of them aſſume a free, cultivated-like growth, and if trained up without grafting to a bearing ſtate, ſome out of a great many may produce tolerable good fruit, though probably not above one or two, in a hundred or more; which however, is the method by which all our fine varieties of fruit were firſt obtained, and the ſorts afterwards encreaſed and continued the ſame by grafting and budding them upon proper Stocks; ſo that for experiment, might ſelect a few of the moſt promiſing of any of theſe ſeedling Free Stocks if thought convenient, tranſplanting them by themſelves, to try to gain new varieties; but allotting however, the general ſupply to remain for Stocks, for the reception of grafts and buds of the choicer kinds of the already-acquired fruits for farther propagation.

Dwarf Stocks.—Theſe are raiſed from low-growing trees, ſome nearly of a ſhrub-like nature, and others of but a very moderate tree-growth, being occaſionally employed as Stocks on which to graft and bud trees, intended as the lower and middling ſorts of dwarfs, either for walls or eſpaliers, or as dwarf ſtandards in ſmall gardens, and to plant in forcing-frames, or to pot for forcing, or curioſity, &c. ſuch for inſtance, the paradiſe apple and codlin Stock for dwarfing apples, the quince Stock for pears, the bird cherry and morello cherry Stock for cherries, the black bullace and muſcle Stock for dwarfing apricots, dwarf almond for peaches and nectarines, when deſigned to have theſe trees of a very dwarfiſh growth, either to pot for curioſity, or for forcing in ſmall forcing-frames.

Obſerving, the moſt dwarfiſh kinds of Stocks of the above are, the paradiſe Stock, bird-cherry, black bullace, and dwarf almond; all of which being of very moderate growth, when uſed as Stocks, they dwarf the trees grafted thereon exceedingly, the head remaining within very ſmall compaſs, and ſhooting moderately into wood, ſoon forms for bearing abundantly in proportion

portion to their ſize; they however are not proper for any general uſe as common dwarf-trees, as they never attain a due ſize ſufficient to produce any conſiderable quantity of fruit, and are rarely of long duration; ſo that a few only are proper for variety, or for very ſmall gardens, or to pot, or for forcing as aforeſaid.

But as to the codlin dwarf Stocks, quince Stock, morello cherry, and muſcle-plum Stocks, they being but moderately dwarf, are proper Stocks for the middling, or larger kinds of dwarf trees, either for walls or eſpaliers, or dwarf ſtandards.

All of which dwarf Stocks both of the moſt dwarfiſh growers, and middling growth, are generally raiſed either from ſuckers, layers, and cuttings, as hereafter directed.

But we now proceed to exhibit the liſt of all the principal ſorts of Stocks comprehended in the above three kinds; crab Stocks, free Stocks, and dwarf Stocks, under the names of the reſpective genus, ſpecies, &c. in which they are uſed for grafting and budding.

*Liſt of the various Sorts.*

As it is therefore of importance to know all the different ſorts of Stocks eligibly adapted for the reception of grafts and buds of the various genera, ſpecies, and varieties of trees uſually propagated by grafting and budding; particularly, all the fruit-tree kinds, and ſome others, we will exhibit under this head a liſt of all the principal ſorts in general uſe, arranging them ſeparately under the name of the ſpecies or variety to which each ſort is peculiarly adapted as Stocks, for the reception of their reſpective grafts and buds.

For apples (*Pyrus malus*).

The Stocks for all kinds of apples, are their own kind, raiſed from the kernels of any of the cultivated apples or crab for common ſtandards, and the larger kinds of dwarfs; though the wild crab Stock is often eſteemed preferable to the free Stock for its hardy and durable nature, on which to graft common ſtandards, and dwarfs for eſpaliers, as being ſuppoſed to render them of more hardy growth and longer duration; and for lower dwarfs, the codlin and paradiſe Stock are occaſionally uſed; the former for middling dwarfs, and the latter for the ſmalleſt dwarfs, when required for ſmall gardens, &c.

All theſe Stocks for apples are eaſily raiſed, the free Stock and crabs from the kernels of the fruit, and the codlin and paradiſe Stock from ſuckers, layers, and cuttings. See PYRUS MALUS.

For the pear, (*Pyrus Communis*).

The pear-tree is grafted and budded principally on pear Stocks for general uſe, and occaſionally on quince Stocks for dwarfs; raiſed, the former chiefly from the kernels of any ſort of pears; and the latter freely by ſuckers, layers, and cuttings.

Though the pear Stock is always to be preferred for the general ſupply; raiſed from the kernels of the beſt ſummer and early autumn pears, being the moſt eligible Stock on which to graft or bud for all common Standards, and the larger dwarf pears for high walls and eſpaliers.

But to raiſe either ſtandards or dwarfs of a more moderate growth, they are occaſionally worked on quince Stocks, generally raiſed from ſuckers, layers, or cuttings as aforeſaid; for the quince-trees being low moderate growers, when uſed as Stocks for any kind of pears, they dwarf the trees pretty conſiderably, rendering them more proper for ſmall gardens, and for low walls and eſpaliers, or dwarf ſtandards; and the trees often commence a bearing ſtate ſooner than on ſtrong-growing pear Stocks: remarking however, this ſort of Stock is in more eſtimation for the melting pears, than the hard breaking kinds, being ſuppoſed to improve the fruit of the former, and render the latter ſtony; but the quince Stock at any rate, unleſs growing on a ſtrong moiſt ſoil, rarely furniſh ſuch proſperous pear-trees as the pear Stock, nor prove of ſo long duration.

Sometimes, alſo to form dwarf pears, white-thorn Stocks, raiſed from ſeed, were formerly in repute, but are very improper, as they have a bad effect in rendering the fruit ſmall and hard, and the trees are rarely proſperous for any long duration.

Therefore the pear Stock is greatly preferable to uſe for grafting or budding all the ſorts of pears for the general ſupply; obſerving however, as the goodneſs of a pear is often improved or diminiſhed by the nature of the Stock on which it is grafted, ſo it is of importance to uſe principally free Stocks raiſed from the kernels of the beſt ſummer and autumn pears, and being raiſed, if any among

among them aſſume a wild crab-like appearance, reject them, eſpecially for the prime pears, which ſhould be worked always on the fineſt free-ſhooting Stocks of the moſt cultivated-like growth.

And ſometimes to improve the quality of any particular choice kind of pears as much as poſſible, ſome double work them, i. e. graft the beſt ſorts into free Stocks in the ſpring, which ſhooting the ſame year, then about midſummer or ſoon after, bud the young ſhoots of the graft with buds of the prime ſorts of pear, ſuffering only the ſhoots from the budding to run up to form the tree: thus the breaking kind of pears are often rendered leſs hard and ſtony, and the melting property of others conſiderably improved; but this double working is not intended for general propagation.

Both the ſorts of Stocks for pears are eaſily raiſed by the methods above noticed, and as hereafter directed.—See PYRUS *Communis*.

For quinces (*Pyrus Cydonia.*)

Two ſorts of Stocks are occaſionally uſed for this tree, viz. that of its own kind, and the pear Stock raiſed, the quince Stocks from ſuckers and cuttings, &c. and the pear kinds from the kernels of any ſort of pears: but as all the varieties of quinces are ſo expeditiouſly raiſed the ſame with certainty by layers and cuttings, renders the raiſing of Stocks for grafting or budding them on, almoſt unneceſſary. See PYRUS *Cydonia*.

For plums *(Prunus domeſtica.)*

This tree is worked only upon plum Stocks, raiſed from the ſtones of any ſort of cultivated plum, and by ſuckers and layers thereof; as plums propagate alſo freely by theſe methods, and are certain methods of propagation to obtain any particular variety of free plum Stock when required; ſuch for inſtance, as the muſcle-plum Stock, which many prefer as the beſt Stock of all on which to work the finer kinds of plums, as generally producing very thriving and durable trees, raiſing it, not from ſeed which would vary exceedingly, but principally by ſuckers from the root of real muſcle plum-trees, or of thoſe worked upon the true muſcle Stock; or from layers alſo of the muſcle-plum tree: obſerve however, plums almoſt in general ſucceed equally well on any kind of free plum Stock; and therefore, the general ſupply may be raiſed from any ſort of plum, either by ſeed or ſuckers, &c. as may be convenient; as directed hereafter.

The plum will alſo grow upon the apricot and cherry Stock, but not thrivingly for any great duration.—See PRUNUS *domeſtica*.

For cherries (*Prunus Ceraſus.*)

The proper Stock for this tree, is that of the cherry kind only; viz. the great wild cherry Stock for large trees, the cultivated garden cherries for more moderate growths, and the bird cherry Stock for ſmall dwarfs; raiſed, the two former from the ſtones of the fruit, and the latter alſo by ſeed, or by layers and cuttings.

But as for general uſe, the wild black and red cherry Stocks, being ſtrong free growers, are preferable, on which to raiſe all common large ſtandard cherries particularly; alſo the larger dwarf-trees for high walls and eſpaliers; as theſe Stocks being of ſtrong hardy growth, generally produce larger, more hardy, and durable trees than the cultivated cherry Stocks; though in default of theſe wild Stocks, may uſe Stocks raiſed from any of the cultivated garden cherries, to raiſe moderate ſtandards and ſmaller dwarf-trees; it is however of importance to raiſe the general ſupply of large trees on the wild cherry Stock, for the reaſons abovementioned.

Sometimes Stocks of the morello cherry, as being but a moderate grower are uſed, on which to raiſe the ſmaller dwarf cherrry-trees for low walls and eſpaliers, or moderate ſtandards, for ſmall gardens, &c. but remarking of the morello Stock, that if raiſed from layers you will be more certain of having the real ſort in its naturally moderate growth.

And Stocks of the common bird-cherry (*Prunus pudus*), being the loweſt grower of the cherry kind, is uſed, on which to raiſe very dwarf cherry-trees, either to plant in forcing frames, or to pot for forcing, &c. are raiſed plentifully from cuttings, and have the effect of dwarfing trees worked thereon exceedingly, ſo as to bear fruit when but one or two feet high; and they ſhooting very little to wood, generally bear abundantly for their ſize.

Cherries will alſo grow upon plum, apricot, and laurel Stocks as being all of the ſame genus, but not proper for general propagation, only by way of curioſity or experiment.

All the varieties of cherry Stocks are raiſed with great facility by the methods

above hinted and hereafter exhibited.—See PRUNUS *Cerasus*.

For apricots (*Prunus Armeniaca.*)

The apricot proves the moſt durable on Stocks of the plum kind only, viz. common plum Stocks of any variety for all common wall, eſpalier, and ſtandard trees; and the black-bullace Stock for ſmall dwarfs; raiſed, the plum Stocks from the ſtones of any kind of cultivated plum, or by ſuckers from the root; and the bullace from ſeed, ſuckers, and layers.

But always chuſe the plum Stock on which to raiſe the general ſupply of apricots for common uſe, which ſucceed almoſt equally well upon Stocks of any kind of plum, though they probably may prove the moſt ſucceſsful on the muſcle-plum Stock, like peaches, &c. but as no great difference is diſcovered, we may uſe any kind of plum Stocks that can be the moſt readily obtained, on which to raiſe all our principal apricot-trees, for walls, eſpaliers, and ſtandards.

And the bullace Stock is only uſed occaſionally on which to raiſe very ſmall dwarfs for low walls, or to plant in pots, or in forcing frames for forcing.

Note, the apricot will grow on its own, and on peach and almond Stocks raiſed from the ſtones, but never ſo proſperous for any duration.—See PRUNUS *Armeniaca*.

For peaches (*Amygdalus Perſica*).

Several ſorts of Stocks are occaſionally uſed for peaches; viz. almond Stocks, peach, nectarine, apricot, and plum Stocks, all raiſed from the ſtones of the fruit, and the latter alſo by ſuckers and layers; but the plum Stock being the moſt hardy, is the moſt eligible for general uſe.

For the peach is not equally ſucceſsful and durable on all thoſe kinds of Stocks; on thoſe of the almond, peach, nectarine, and apricot, although they take freely, ſhoot fair and promiſing for ſome years, yet are frequently apt to gum exceedingly, and prove but of middling duration; ſo that the free plum Stock is preferable for all the ſorts of peaches and nectarines, as being productive of the moſt hardy, thriving, and durable trees; though it is remarkable, one ſort of plum Stock in particular, is generally preferable to all the others on which to work peaches, as producing the moſt proſperous trees, and improving the fruit; which is that of the muſcle-plum, formerly hinted, if raiſed genuine; not from the ſtones, for, as obſerved before, the ſeedlings run into many varieties very different from the original; but ſhould be raiſed real, from ſuckers or layers of the true muſcle-plum-tree, or by ſuckers from the roots of ſuch old peach, nectarine, plum, &c. as are worked on muſcle-plum Stocks, which generally ſend up plenty from the roots annually; planting them off at one year's growth into the nurſery to train for uſe: however, for want of a ſufficiency of this approved Stock, recourſe muſt be had either to ſeedling Stocks raiſed from the ſtones of the muſcle or any other kind of plum, or ſuckers, or layer Stocks of any of the plum varieties; but always giving preference to the true muſcle-plum Stock where it can be obtained.

Double Stocks or double working, is ſometimes uſed for the more delicate peaches, to improve their bearing and flavour of the fruit; and conſiſts of firſt budding in the common way, by inſerting buds of any ſtrong-ſhooting peach, almond, or apricot into a plum Stock; and the buds ſhooting out ſtrongly next ſummer, then upon the main ſhoot from the bud, perform the ſecond or final inoculation with buds of the approved ſort intended for propagation, ſuffering the ſhoots from the ſecond budding only to grow up and form the tree; and by this practice the delicate flavour of ſome ſorts of peach fruit is more certainly preſerved, and ſometimes improved.

For nectarines (*Amygdalus Nuciperſica.*)

The nectarine is worked upon the ſame Stocks as the peach, viz. almond, peach, nectarine, apricot, and plum; all raiſed as obſerved above for the peach-tree: preferring however, the plum Stock for general propagation, and if the true muſcle-plum Stock, as for peaches, it may improve the proſperity of the trees.—See the Stocks for peach trees above.

For almond-trees (*Amygdalus communis.*)

The almond-tree when raiſed for its fruit, the approved varieties may be budded into Stocks of any ſort of almond, peach, nectarine, apricot, or plum, raiſed from the ſtones, and the latter alſo from ſuckers, &c. but the trees are generally the moſt hardy and durable on plum Stocks.

For medlars (*Meſpilus Germanica.*)

About three or four different Stocks are occaſionally uſed, on which to raiſe the approved varieties of eatable medlars, viz. medlar Stocks, white-thorn, pear, and quince Stocks,

Stocks, raiſed, the three former from ſeed, and the latter expeditiouſly from ſuckers, layers, and cuttings; the white-thorn Stock is very commonly uſed for theſe trees, but free pear Stocks raiſed from the kernels of good ſummer or autumn pears are rather preferable for all the varieties of common medlar, which on theſe Stocks generally aſſume a more free growth, and produce the fruit in greater perfection.

For ſweet Service-trees *(Sorbus domeſtica.)*

The houſhold or ſweet ſervice when deſigned as a fruit-tree, have the approved varieties grafted or budded upon proper Stocks; either their own Stocks raiſed from the ſeed, or on pear or quince Stocks raiſed as mentioned juſt above for medlar and other trees; though the pear Stock is preferable to the quince on which to work this tree to have it large and durable.

For the wild maple-leaved Service berry-trees *(Cratægus torminalis.)*

This tree being ſometimes cultivated in the garden and orchard for its eatable berries; and to obtain or continue any particular good variety with certainty, they are occaſionally raiſed by grafting or budding, and the proper Stocks are either their own kind, or haw-thorn Stocks, raiſed from the ſeed; they will alſo take upon pear Stocks, &c.

For hazel nuts, filbert nut, &c. (*Corylus avellana*).

Any approved variety may be continued the ſame with certainty, by graſting and budding upon Stocks of the common nut-tree, raiſed from the nuts or ſuckers from the root; though as all the varieties may be readily encreaſed, and continued the ſame by layers, &c. with great facility and abundance, the grafting or budding is not commonly practiſed in their propagation, only in particular caſes, in default of layers or ſuckers of any particular good ſort of nut, and that cuttings or buds for grafting or budding, can be more readily obtained from neighbouring trees of the ſorts intended; and having raiſed a few trees by this method, they in two or three years furniſhing plenty of branches to raiſe a more plentiful ſupply by layers; and theſe layer-raiſed trees, being wholly the ſame top and root, ſuckers from the bottom are equally eligible as grafting and laying, for continuing any approved variety.—See CORYLUS *avellana.*

For orange-trees (*Citrus Aurantium.*)

The orange-tree is worked upon Stocks of their own kind only, viz. either any kind of orange, lemon, or citron Stocks, raiſed from the kernels of the fruit; though of the orange kinds, the Seville orange, as being a very free ſtrong ſhooter, is generally preferred for orange Stocks; but the lemon and citron being alſo free growers form very proper Stocks on which to raiſe any variety of orange. See CITRUS *Aurantium.*

For lemon and citron trees (*Citrus Medica.*)

Both theſe varieties are alſo budded or inarched upon lemon, citron, or orange Stocks, raiſed from the kernels of the fruit, as obſerved above for oranges. See CITRUS *Medica.*

Thus far is principally all the ſorts of Stocks commonly uſed for fruit-trees, that are either generally, or occaſionally raiſed by grafting and budding.

For the ſeveral other ſorts of fruit-trees, not mentioned in the above liſt of Stocks, ſuch as the vine, fig, mulberry, currant, gooſeberry, barberry, walnut, cheſnut, &c. in their ſeveral varieties, being, in the firſt ſix ſorts particularly, raiſed and continued the ſame with greater facility by layers, ſuckers, and cuttings, which renders the propagation by grafting and budding unneceſſary; and the walnut and cheſnut not ſucceeding perfectly by theſe methods to become large thriving trees, are raiſed from the nuts: however, any approved variety of moſt of the above-mentioned ſorts, may alſo be tried occaſionally by grafting and budding upon proper Stocks by way of experiment; and the eligible Stocks are principally thoſe of their own kind, raiſed ſome from ſuckers, layers, and cuttings; others alſo from ſeed, as exhibited in the culture of the reſpective ſorts, under their proper genera.

For foreſt and ornamental trees, flowering ſhrubs, &c.

As to the Stocks proper for ſuch foreſt-trees, ornamental trees, and flowering ſhrubs, &c. that are occaſionally raiſed by grafting and budding, either to improve or continue any particular variety, they are for the general part each worked on Stocks of its own kind, as obſerved above for the generality of fruit-trees; but as in theſe kind of trees, the variation of the ſeedlings being not ſo numerous and material as in the fruit-tree kind, they do not require to be ſo generally raiſed by graſting or budding, only for ſome particularly valuable variety, or any of peculiar property, ſuch as variegated, or other remarkable leaved kinds, double-

flowering variety, or other curious flowering ſorts, &c. that cannot be continued the ſame by ſeed, but only either by grafting or budding, or by layers and cuttings; though as the two latter methods are not convenient in all ſorts, recourſe is had to grafting and budding to encreaſe the above varieties with certainty of the kinds intended, without farther variation: working the reſpective ſorts principally each upon Stocks of its own kind, chuſing the ſtrongeſt free ſhooters, raiſed either from ſeed or ſuckers, &c. as mentioned in their culture, each ſort underits proper genus as obſerved on former occaſions.

*General Hints for Experiment.*

Sometimes for variety and curioſity in any ſort of fruit-trees and others, the ſame Stock is made to ſupport two, three, or more different varieties of fruit, grafted or budded, either all into the Stock, being previouſly trained with branches forking off for that purpoſe one for each graft, or by cleft, or crown-grafting ſingle large Stocks with two or more different ſorts; or in ſmaller ſingle Stocks by inſerting two or more different buds; likewiſe any Stock being ſingly grafted or budded, may inſert different ſorts into the ſhoots ariſing from the ſaid graft, or buds; and thus may have two, three, or more ſorts of apples, on the ſame root for curioſity; the ſame of pears, plums, cherries, and moſt other fruits, &c. that are chiefly ſpecies or varieties of the reſpective ſorts in the ſame genus, or that which is very nearly allied, as we have already exhibited; and in ſeveral inſtances, by the ſame rule and method, may have different ſorts of fruit upon the ſame Stock, as plum, cherries, and apricots all on a plum Stock, or peaches, nectarines, and apricots on the ſame, or on Stocks of their own kind; and pear, medlars, and quinces upon the pear Stock; alſo red and white currants, or currants and gooſeberries, both on a currrant or gooſeberry Stock; or white and red grapes on any vine Stock: likewiſe red and white roſes, or other different ſorts, upon any common roſe Stock; and the ſame of numerous other trees and ſhrubs, ſpecies and varieties of one genus; remarking however, this is not recommended for any general practice, but only for a tree or two of any particular genus or ſpecies, by way of experiment, variety, and curioſity.

*Method of raiſing the Stocks in general.*

With reſpect to the method of raiſing all the different ſorts of Stocks, it is occaſionally by ſeed, layers, ſuckers and cuttings, as hinted above in the liſt for each particular ſort.

By Seed.—Numerous ſorts of Stocks are eaſily raiſed from ſeed, conſiſting of the kernels and ſtones of the fruit, of the reſpective trees, ſuch as the kernels of the crab-apple, and all the other apple kinds; kernels of all the ſorts of pears; and the ſtones of plums, cherries, apricots, peaches, nectarines; the ſeeds or ſtones of medlars, ſervices, haws, &c. when deſigned for Stocks; all of which are to be obtained in autumn from their reſpective fruits when fully ripened; previouſly laying the larger fruits together in an heap, and bruiſe them; ſuffering them to lie ſome time to decay as the different ſorts may require, in order that the pulp may be more readily cleared from the kernels and ſtones proper for ſowing; or, the kernels of apples and pears may alſo be procured from any of the accidentally rotten fruits in the fruitery; and ſometimes both apple, pear, and crab kernels are occaſionally obtained from the cyder preſſes after the fruit have been preſſed for cyder, perry, verjuice, &c. but the ſtones of plums, cherries, apricots, and the like, muſt be procured from the fruits as above, as ſoon as they are ripe; which together with all the other ſorts, may be ſowed as ſoon as poſſible, each ſort ſeparate.

All the ſorts, both kernels, ſtones and other ſeeds, are to be ſowed in beds of common earth in the nurſery, either directly in autumn, or preſerved in ſand till February, and then ſowed.

Obſerving however, that for the general part, it is eligible to ſow them principally in autumn or early part of winter, as October, November, or December, unleſs the ground proves of ſuch a wet cold nature, as to endanger their rotting in winter; and that it ſhall ſeem neceſſary to preſerve them in ſand in a dry apartment until February, as before obſerved.

However, in any common moderately dry ſoil, it is adviſeable to ſow them at once in autumn, or as ſoon as they can be obtained, as it will be both leſs trouble, and may prove more ſucceſsful in forwarding their

their germination; and if the winter ſhould prove ſevere, the beds of the more tender kinds, as almonds, and peaches, &c. may be covered with dry litter to defend the ſeed from the froſt.

The method of ſowing all the ſorts is in beds of any common light earth in the open nurſery or ſeminary, ſowed either by bedding in, or in drills, as below. — See NURSERY.

Having however previouſly digged the ground, then if intended to bed in the ſeeds, divide the ground into four-feet-wide beds, with foot-wide alleys between; and then with a rake or ſpade trim the earth from off the top of the beds evenly, into the alleys from about an inch, to an inch and half, or two or three inches deep, according to the ſize of the different ſeeds; this done, ſow the ſeeds all over the ſurface moderately thick, and after preſſing them all evenly down into the earth with the back of the ſpade, cover them in with the earth from the alleys evenly, the depth as above; the kernels of apples, crabs, pears, &c. near an inch deep, the ſmaller ſtones about an inch and a half, and the larger ſorts full two inches deep. But if it is deſigned to ſow them in drills proceed thus, having digged the ground, and formed it into four-feet-wide beds as above adviſed, then draw drills with an hoe, either lengthways or croſs the bed, from one to two or three inches deep, and ſix inches aſunder at leaſt, ſowing the ſeeds, &c. in the drills, and directly cover them in with the earth the depth of the drills. — See SOWING of SEED.

After having performed the ſowings as above, if the ground is much infeſted with mice or other deſtructive animals which often attack theſe kind of ſeeds in winter, it is adviſeable to ſet different ſorts of traps and baits, for their deſtruction.

The different ſeeds being thus ſowed, they will all germinate freely in the ſpring, and ſoon come up the ſame ſeaſon; obſerving previous to the ſprouting or appearance of the ſeedlings above ground, that if the ſurface of the bed proves moſſy, or that the top is hard bound or caked, it is beneficial culture to ſtir the ſurface lightly with a ſmall iron rake, alſo if harſh dry weather prevails, to give frequent moderate waterings both before and after the plants are up; repeating the waterings occaſionally in dry weather all ſpring and early part of ſummer, to encourage a free ſtrong growth; being likewiſe careful to keep the beds very clean from weeds by diligent hand weedings; and by thus giving every encouragement of culture, the ſeedling Stocks will grow ſo freely all ſummer, as by autumn or ſpring following, will be moſtly of proper ſize to plant out into nurſery-lines in the open quarters, in rows two feet aſunder, to remain for grafting and budding; though if they have made but middling progreſs this firſt ſummer in the ſeed-bed, and are rather ſmall and weakly, may plant out only the ſtrongeſt, leaving the reſt growing until next autumn, when they will be all of full ſize for planting out wholly into the nurſery quarters.

Therefore when the Stocks are of due ſize for removal from the ſeed-bed, chuſe for their reception ſome of the open quarters of the nurſery, preparing the ground by trenching two moderate ſpades deep; then forking the ſeedlings up out of the ſeed-bed, ſhorten any perpendicular tap-root and long ſtragglers, but leave all their tops entire, and then proceed to plant them in lines, either by trench-planting, ſlit-planting, or dibble-planting, as the ſize of the plants admit (ſee PLANTING), marking out the rows two feet aſunder, and ſet the plants one foot or fifteen inches apart in each row, all in an upright poſition; and having planted one row, then tread the earth gently all along cloſe to the roots of the plants, to fix them firmly in the earth all evenly in a ſtrait range and erect poſture; and ſo proceed row and row till all is planted, levelling the ſurface of the ground between all the rows with your ſpades.

As to their future culture till grafted or budded, it conſiſts in occaſional waterings the firſt ſpring, hoeing the ground every ſummer to kill weeds; digging between the rows annually in winter or ſpring; and of training the Stocks each to one ſtem, preſerving their top always entire; but trimming off ſtrong laterals below, to encourage the ſtrength of the main ſtem, and the aſpiring of the top as faſt as poſſible; whereby they will be fit for grafting or budding in, from one to two or three years after planting.

They are generally of proper ſize for working, when from about the ſize of a large gooſe-

goose-quill already obſerved, to the thickneſs of a man's little finger or a little more; but the ſooner they are worked after having obtained due ſize, the better they will ſucceed, and the ſooner you will have them form trees of the ſorts intended. — See GRATFING and INOCULATION.

But ſuppoſing the Stocks to have ſhot freely the firſt ſummer after planting out from the ſeed-bed, many of them will probably be of due ſize to graft the following ſpring and ſummer, at five or ſix inches height, to form dwarfs for walls and eſpaliers, &c. or even in ſome ſorts, for full or half Standards; provided the firſt main ſhoot from the graft or bud is trained up ſingly, two or three years to form the ſtem, of from four or five, to ſix or ſeven feet ſtature: however, if the Stocks have growed but moderately the firſt ſeaſon, and that they are not generally in a condition for the operation of grafting or budding, let them have another year's growth, or till arrived to the before-mentioned ſize, which may be ſufficient for dwarf-trees; alſo occaſionally for ſtandards, when the graft or bud is to form the ſtem, as above obſerved; but when deſigned for ſtandards, and the Stock to form the ſtem, they muſt be permitted to ſtand two or three years longer, trimming off ſtrong ſhoots below, and ſtill preſerving the leading top ſhoot entire to continue the elongation of the ſtem to an eligible ſtature, to receive the graft or bud at five or ſix feet height for full ſtandards, and three or four for half ſtandards; ſo that theſe ſtandard Stocks being arrived to about ſeven feet height for full, and five or ſix feet for half ſtandards, and of the before-mentioned thickneſs at top, in the place where the graft or bud is to be inſerted, they are of due ſize for working.

By Suckers.—Several ſorts of fruit and foreſt-trees, &c. furniſh many ſuckers from the root annually, very proper to be tranſplanted for Stocks; ſuch for inſtance, as codlins, plums, and quinces; alſo peach, nectarine, and apricots on plum Stocks, pears on quince Stocks, any ſort of apples on codlin Stocks; likewiſe moſt ſorts of elms, and many other foreſt and ornamental kinds. And the ſuckers of all theſe trees being planted off at one year's growth in autumn or winter, is a very expeditious and eligible method of raiſing ſeveral ſorts of Stocks; as that after being tranſplanted into the nurſery, they often in one year commence proper Stocks for the reception of grafts and buds; and ſometimes many of them will be fit for budding in the ſummer following at the proper budding ſeaſon, or for grafting the ſpring after.

Likewiſe in ſome inſtances, ſuckers afford an opportunity of raiſing Stocks of any particular variety required with certainty, ſuch as the muſcle-plum for peach Stocks, codlin for dwarf apples, and the like particular kinds; for when the trees productive of the ſuckers are either wholly top and root of the variety intended, or that they form Stocks to other trees, the Stock and root ſtill remaining of the intended ſort: and in either caſe, all the ſuckers prove invariably the ſame as the parent-tree; but this is only to be particularly regarded when any particular variety of Stock is required; in other caſes may uſe ſuckers of all other fruit-trees, &c. indifferently for Stocks.

They are generally fit to take up for the purpoſe of Stocks when of one year's growth, about the ſize of a tobacco-pipe or but little bigger, and ſhould be collected in autumn or early part of winter; taking them up as well rooted as poſſible, cutting off all knots or knobbed woody parts of the old roots that may adhere to their bottom, trim ſtraggling fibres, and cut off all ſide-ſhoots from the ſtem, then plant them in rows two feet aſunder, and one foot diſtant in the lines; treading the mould gently to their roots, and finiſh the work by levelling the ſurface between the rows: thus they will readily take root, and in ſpring ſoon ſhew ſigns of free growth.

Then as to culture till grafted or budded, it is nearly the ſame as the ſeedling Stocks, keeping them clean from weeds in ſummer by hoeing; and probably ſome of the ſtrongeſt ſhooters may be fit to bud in July or Auguſt following; though the general part will require two years growth before they are proper for working, ſtill continuing them all to one ſtem, by timely diſplacing ſtrong laterals; and preſerve their top or leading ſhoot generally entire until grafted, &c. which may be performed when they are of the ſizes before mentioned.

By Layers.—Some ſort of Stocks, both of fruit and other trees, may alſo be raiſed occaſionally by layers; and when any particular

ticular variety of Stock is required, ſuch as the paradiſe Stock for apples, muſcle-plum for peaches, &c. they may be obtained of the real ſort always with certainty, by layers of the ſhoots of ſuch trees as are wholly of the intended ſort; but as this method of raiſing Stocks would be attended with great trouble for general grafting and budding, it is only practiſed occaſionally when a ſufficiency of any particular ſort of Stock intended, cannot be obtained by ſuckers, &c. ſo that in autumn or winter, chuſing the young ſhoots either of ſuch trees whoſe branches naturally grow near the ground, or have been cut down low while young, to force out branches near the bottom, furniſhing ſhoots properly ſituated for laying; which being ſlit-layed in the common method, they will be rooted by autumn following, and fit to plant into the nurſery; managing them as directed for the ſeedling and ſucker Stocks.

By Cuttings.—As ſome ſorts of trees proper for Stocks, grow freely by cuttings; ſuch as codlins, quinces, bird-cherry, paradiſe Stock, &c. a ſupply of Stocks of theſe ſorts are ſometimes raiſed by this method; chuſing cuttings of the year's ſhoots in autumn, plant them in the nurſery in a ſomewhat ſhady border, giving occaſional waterings the following ſpring and beginning of ſummer in dry weather, and they will be well rooted by next autumn, then tranſplanted in nurſery-rows two feet aſunder, managing them as the others.

Remarking of the Stocks in general, raiſed in either or by all the above methods; that as we formerly obſerved they muſt always be continued to one upright ſtem, with their top entire; except any ſhould aſſume a ſtunted or crooked growth, in which caſe, head them down to the ground in ſpring, they will puſh out ſtrong from the bottom the enſuing ſummer, training them to one ſtem, and with their leading top-ſhoot entire as aboveſaid; and according as all the ſorts advance in growth, diveſt them of ſtrong lateral ſhoots below, repeating it particularly in the taller ſtandard Stocks to encourage their upright direction more expeditiouſly to the proper grafting and budding height.

With reſpect to the different methods of grafting and budding the ſeveral ſorts and ſizes of Stocks, the grafting them is occaſionally performed different ways according to the ſize of the Stock; and the budding them is performed only by one method to all ſorts; remarking as to grafting, the method called whip-grafting is conſiderably the moſt eligible for general practice, and is always performed upon ſmall Stocks: likewiſe budding is alſo the moſt ſucceſsfully performed upon ſmall or moderate ſized Stocks; for example, young Stocks from the ſize of a large gooſequill, to the thickneſs of the little finger, in the part where the graft or bud is to be inſerted, are of the moſt eligible ſize for general working; for all nurſery Stocks, performed either by whip-grafting, or by inoculation as the different trees may require: though cleft grafting is alſo occaſionally performed on ſmall Stocks, but not ſo ſucceſsfully as whip-grafting, ſo is more commonly practiſed for ſuch Stocks as are too large for that method of grafting; but large Stocks of an inch or more diameter, ſucceed very well by cleft grafting; alſo ſometimes tolerably by budding, but not in general ſo effectually as ſmaller Stocks, &c. above mentioned. And ſuch Stocks as have ſtood to grow very large, perhaps two or three inches or more in diameter, may alſo be grafted occaſionally with tolerable ſucceſs, but do not ſucceed by inoculation: and crown-grafting is generally the beſt method for ſuch large Stocks; ſometimes alſo cleft-grafting is practiſed by making ſeveral clefts round the top of the Stock, and inſert one graft in each, though the working of theſe very large Stocks is the moſt generally, and ſucceſsfully practiſed when they are growing in the places where they are finally to remain; but for the methods of performing the operations of grafting and budding the various ſorts of Stocks for raiſing the ſeveral kinds of dwarf and ſtandard trees, ſee GRAFTING and INOCULATION; alſo the ſeveral ſorts of trees raiſed by theſe methods, as apples, pears, plums, peaches, &c. each in its reſpective genus.—Alſo DWARF TREES, STANDARD TREES, WALL and ESPALIER TREES.

After grafting and budding the ſeveral ſorts of Stocks, they may be then ſaid to commence trees of the name of the reſpective ſorts with which they are worked, eſpecially after the graft and bud begins to ſhoot, which growing up into branches, forms the new tree of the ſort intended.

STOOLS,

STOOLS, to furniſh layers.

Stools are headed-down trees and ſhrubs in the nurſery, appropriated for the production of an annual ſupply of lower ſhoots or branches near the ground, eligibly ſituated for effecting the propagation of the reſpective ſorts by layers. See LAYING.

Such trees and ſhrubs as are deſigned for Stools to furniſh layers for the work of propagation, are generally headed down to the bottom in the nurſery, &c. in order to force out more effectually a plenteous ſupply of branches near the ground, to afford layers conveniently ſituated for laying down in the earth as aforeſaid; which being layed in autumn, winter, or ſpring, they ſtriking root in a year or two; and each layer commencing a diſtinct plant, are planted off into the nurſery in autumn following; the Stools remaining, ſend out a farther ſupply of lower ſhoots the following ſummer for laying as before; and thus the remaining Stools continue affording a plentiful ſupply of branches from the bottom, fit for laying annually, or every other year at leaſt; and hereby propagate the ſorts intended with great facility and abundance.

Therefore, as many ſorts of trees and ſhrubs are with great facility propagated by layers, a ſufficient number of the reſpective ſorts in the nurſery, &c. ſhould be appropriated for Stools, in proportion to the ſupply required of the ſorts intended, whether in the public nurſeries for ſale or for private plantations; chuſing for this purpoſe ſome ſtrong young trees and ſhrubs, which being planted in the nurſery, &c. at from five or ſix, to eight or ten feet diſtance, according to their ſize or nature of growth, and after having remained a year or two till firmly rooted, and acquired ſome ſubſtance, then all thoſe of the tree kind, or ſuch others as run up with tall ſtems without affording lower branches near the ground for laying, ſhould in autumn, winter, or early in ſpring, be headed down within a few inches of the ground; by which operation they in ſummer following will puſh out from the bottom plenty of ſtrong young ſhoots commodiouſly placed near the ground for laying, which may be performed the ſucceeding autumn or winter, or if you wait till the ſecond autumn, the firſt ſhoots ſending out many lateral or ſide ſhoots the enſuing ſummer, and thereby probably furniſh five or ten times more ſhoots for laying; and theſe ſmall laterals are often better adapted for rooting, than the firſt vigorous ſhoots that riſe immediately from the ſtool, and each of which layed will form a new plant; however you will order this as it ſhall ſeem convenient, as ſome ſorts may afford a ſufficiency for laying the autumn after they are produced; others may require to grow till the ſecond or third autumn before they are eligible for laying.

As to the method of performing the operation of laying, it being fully explained in all the various ways in practice under its proper head, we will not repeat it here, ſo refer the reader to the article LAYING.

In moſt ſort of Stools where the laying is performed in autumn, or early in winter, the layers are for the general part well rooted in one year, commencing proper plants fit for ſeparation from the Stools in the autumn following, in order for planting out in nurſery rows to be trained for the purpoſe intended; though ſome very hard-wooded ſorts require two ſummers growth in the layer-bed before they are ſufficiently rooted; on the other hand, ſome ſorts being laid in ſummer in the young ſhoots of the year, often effect their rooting freely the ſame ſeaſon, fit for planting off the following October.

However, in all ſorts it is proper to examine the layers in the autumn after they are layed; and all thoſe ſorts that are rooted ſhould then be taken off, ſeparating them with a knife from the Stools, with as much root as poſſible; and directly planted in nurſery-rows a foot or two aſunder; and the more tender ſorts plant in pots for moving under ſhelter in winter, as directed for each ſort under its reſpective genus; then when the layers are all thus planted off, let the remaining Stools be trimmed and dreſſed as below, for providing a freſh ſupply of layers the ſucceeding year.

Every year ſoon after the layers are ſeparated from the Stools, the latter ſhould be dreſſed, which conſiſts of trimming the head by cutting off all parts of old branches and ſcraggy ſtumps within an inch or two of the main Stool; and then dig and level the ground neatly about and between the whole, and in ſpring and ſummer, give occaſional hoeings in dry weather to deſtroy weeds; thus repeating the ſame work of trimming,

trimming, digging, and hoeing every year; and the Stools ſtill remaining, ſupply you with plenty of layers for years to come.

But ſometimes Stools for layers are formed occaſionally of trees, &c. that are conſiderably grown up, not having been headed down to form low Stools, but whoſe branches are of ſome conſiderable height from the ground; and in which caſe, the branches, if flexible and long enough, are bowed down to the earth; or if inflexible and too ſtubborn to bend, are ſplaſhed by making a gaſh or cut on the upper ſide; or if too large for ſplaſhing, or that the nature of the wood will not bear that operation, they are thrown on their ſides by opening the earth about the roots, looſening or cutting thoſe on one ſide to admit of lowering the head ſufficiently for laying the branches in the ground.

Sometimes alſo Stools being formed of grown-up trees, whoſe branches are too high for laying in the full ground, a temporary ſtage or ſcaffold is erected on which to place pots or tubs of earth for the reception of the layers.—See LAYING.

STOVE, or Hot-houſe.

Stoves in gardens are ranges of buildings conſtructed with brick walling behind on the north, and fronted and roofed wholly with glaſs ſaſhes next the ſouth, full upon the ſun; furniſhed internally with a pit or long, wide, and deep cavity for a bark hot-bed; and with flues round the inſide of the walls for fires: the whole calculated to produce a certain temperature of heat at all ſeaſons, peculiarly adapted to the culture of the tendereſt exotic plants from the hot parts of the world; alſo for forcing various plants, both hardy and tender, into flower and fruit, &c. at an early ſeaſon.

Formerly, before the uſe of bark-beds was introduced, all Stoves or Hot-houſes were worked by fire heat only, hence they obtained the name of Stoves.

Theſe Stove departments are generally conſtructed in an oblong manner, ranging in a ſtraight line lengthways nearly eaſt and weſt, with the glaſs front, and top, full upon the ſouth ſun, or inclining a little to the ſouth-eaſt; and in dimenſions, may be from fifteen or twenty, to fifty or an hundred feet long; by twelve or fourteen, to ſixteen feet wide or more in the clear, and from ten to fourteen feet height commonly in the back wall, by five or ſix in front, including the wall, and upright glaſs-work together; and with the whole roof over-head ſloping to the ſouth entirely of glaſs-work, ſupported on proper croſs bearers.

Obſerving however, as to its general ſtructure, a wall of brick-work is firſt formed all round, raiſed behind from ten to twelve, or fourteen feet height, as juſt obſerved; and only two or three feet in the front and both ends, on which to ſupport the glaſs-work; previouſly forming the furnace or fire-place of the flues near the foundation of the back wall outward, at one or both ends according to the length of the building, or may be in the back part of the end walls; the flues, for conducting the fire-heat, to be ranged internally cloſe along the inſide of the back wall, &c. above one another: but as before noticed, the front and end walling is raiſed only from about one to two or three feet height, for the ſupport of the timber framing for the upright glaſſes, nearly head high all along the front, both ends correſponding; a door-way for entrance being formed at one or both ends near the back wall; finiſhing the timber framing of the top or roof over-head in one continued ſlope, from the top of the back wall to that of the crown timber of the front, erecting croſs bars for the ſupport of the ſlope ſaſhes in two or more tiers ſliding one over the other quite home to the crown timbers behind; having no dead roof or cieling in the back part as ſometimes practiſed, but wholly of glaſs to admit the rays of light, &c. equally in every part; all the glaſs-work, both front and top ſaſhes being made to ſlide open occaſionally to admit air, &c.

Within ſide is formed the pit or cavity for the bark bed, and flues for the fire-heat; the pit being ranged nearly the length of the building, ſix or eight feet wide or more, and three deep; either ſunk a little, or raiſed the greater part above ground, nearly equal to the outer front walls, and formed by a ſurrounding thin brick wall, and in which is made the bark hot-bed, both for the reception of tender plants plunged therein in pots, and to aſſiſt in warming the internal air; next to the bark-pit wall, is a path or walk two feet wide generally continued all round; then along againſt the inſide of the main walling are continued the flues conſtructed of brick-work on edge; each flue only eight or nine inches wide in the clear, by two or three bricks on edge deep, ranged horizontally one over the other the whole length

of the back wall, in three or four returns communicating with each other; continued alſo along the end and front walls in one or two ranges, to be uſed occaſionally; furniſhed with a regulator accordingly, to ſlide open and ſhut as required; the whole proceeding from the firſt lowermoſt flue, which communicates immediately from the furnace or fire-place, without ſide, behind, in the bottom, either of the back wall at one end, or in the back part of the end walls as before hinted, and as the ſituation admits; or if very long ſtoves of more than forty feet length, two fire places are requiſite, one at each end; each having its ſet of flues ranging half way; each ſet of flues terminating in an upright chimney at the ends of the back wall without, to diſcharge the ſmoke after having ſpent its heat in its paſſage through all the returns, for the purpoſe of heating the whole ſufficiently to warm the air within; for in winter and early ſpring, fires being made in the furnaces every night, the ſmoke and heat paſſing immediately into the firſt bottom flue, thence quickly tranſmitted through all the others in their ſeveral returns, heating them in its paſſage ſo effectually, as to warm the internal air in the moſt agreeable manner, which together with the bark-bed heat, produces a temperature of warmth proper for the growth of all ſorts of tender exotics, both woody, herbaceous, and ſucculent, from the hotteſt parts of the globe; as ſome ſucceed principally in the bark-bed, others beſt upon the top of the flues and ſhelves, &c. as is generally noticed in the culture of the reſpective ſorts under their proper genera; hinted alſo in the article STOVE PLANTS.

The above is a general ſketch of the dimenſions and formation of a common Stove or Hot-houſe for general uſe, proper for the culture of pine apples, and numerous other tender exotics; as well as for forcing flowers, fruits, &c. but for farther particulars of its conſtruction, ſee the article of its *General Structure*.

But ſome Stoves are built conſiderably more lofty and capacious than the above-hinted dimenſions, when intended to cultivate the taller exotics in the greateſt perfection poſſible, according to their nature of growth: and for which purpoſe there are Stoves erected twenty or thirty feet high in the back wall, with width in proportion; by only five or ſix feet height in the front glaſſes, in order to ſuit low as well as high plants; and with the roof ſloped quite from the top of the back wall to the front, and wholly of glaſs-work, having a capacious bark-pit within, formed moſtly towards the front; behind which is ſometimes a border of earth to receive tall plants in the full ground; ſo in this kind of Stove may cultivate exotics, &c. from the loweſt to almoſt the higheſt ſtature, placing the ſhorteſt growth forward, and the talleſt behind, according to their ſeveral gradations of height.

However, theſe very lofty and capacious Stoves are not recommended for general uſe, they being both very expenſive in erecting, requiring alſo a great force of fire-heat to warm the internal air in winter; and not ſo well calculated for the growth of the general run of exotics, as Stoves of a moderate height: but perſons of fortune and curioſity can indulge their fancy in this reſpect as they think proper.

But the common Stove firſt deſcribed, of from ten to twelve or fourteen feet high behind, and fourteen in width, by five or ſix feet height in front, will prove ſufficient to raiſe a great collection of curious tender plants of middling growth.

Thus in theſe Stove departments, by the conſtant moderate heat of the bark-bed obtained the year round, and occaſional heat of the flues in cold weather, we are able to produce ſuch a temperature of growing warmth in the internal air equally throughout the building, as is eligible for the growth of all ſorts of tender exotics from the hotteſt regions of the Eaſt and Weſt Indies, &c. which in this country could not poſſibly exiſt, in winter eſpecially, without the conſtant ſhelter of ſuch a conſervatory, aſſiſted by the above artificial heats of bark hot-beds and actual fire, by which we can imitate the hot climates of Africa, Aſia, and America ſo nearly, as to raiſe the plants of thoſe countries and make them flouriſh as in their native ſoil, and ſome of them made to yield their fruit in high perfection; exemplified in the *ananas* or pine apple particularly.

Likewiſe, by the aid of Stoves we are enabled to forward many of our hardy plants to early perfection, ſuch as various ſorts of curious flowers, fruits, ſallads, kidney beans, ſtrawberries, &c. probably one, two or

or three months ſooner than they could poſſibly be obtained in the open ground.

Alſo many ſorts of ſeeds, cuttings, and layers of exotics are made to grow freely in the bark-bed of the Stove, that without ſuch aids would not grow at all in this country; likewiſe, even cuttings, &c. of many curious hardy plants that root tolerably in the full ground, may be facilitated very conſiderably in their rooting by the Stove bark-bed.

*Of the different ſorts of Stoves.*

There are however, different ſorts of Stoves uſed occaſionally for different purpoſes, viz. a Bark Stove for common uſe, being accommodated both with a bark-bed and flues: a Dry Stove for ſome particular very ſucculent plants, &c. is furniſhed only with flues for fires, and no bark bed: a Forcing Stove purpoſely for forcing hardy fruits, flowers, &c. to early perfection; being conſtructed, ſome both with bark-bed and flues, and ſome only with flues and no bark-bed. See each ſort deſcribed below under their reſpective heads; BARK STOVE, DRY STOVE, and FORCING STOVE.

BARK STOVE.

The Bark Stove is ſo called, as being furniſhed with a pit for a bark-bed, as well as with flues for fire-heat; its general conſtruction has already been deſcribed; and is the moſt univerſally uſed, as the moſt eligible Stove for the general culture of all kinds of the tendereſt exotics, as well as for forcing hardy plants, flowers, and fruits occaſionally to early perfection; for the bark-bed being deſigned to effect a conſtant moderate moiſt heat the year round; and the flues are uſed occaſionally for fire-heat in winter, or during the cold weather, to produce an additional warmth in the internal air, as may be requiſite at that ſeaſon; the bark-bed being formed of that uſeful material tanner's bark, commonly called tan, (ſee BARK BED); and being made the whole width, depth, and length of the bark-pit, is productive of a uniform moderate growing heat of long duration, peculiarly adapted for the immediate reception of many of the tendereſt exotics, that require to be conſtantly plunged in their pots in the bark bed; ſuch as the pine-apple, &c. in order to enjoy the benefit of that durable, moiſt, bottom heat about their roots, peculiar to bark hot-beds only, whoſe heat alſo evaporates and warms the air of the Stove at all times; and when the cold in autumn and winter commences, the bark-bed alone not producing a ſufficient temperature of heat to warm the internal air effectually, fires are made in the furnace of the flues every night, alſo on days occaſionally during the winter ſeaſon, to produce an additional internal heat, as before obſerved; ſo as the whole may both effectually keep out froſts and the effects of cold damps, and ſupport a conſtant regular temperature of heat within adapted to the nature of the plants of this department; being generally directed in this by a well graduated botanical thermometer placed conſtantly in the Stove, diſtant from the fire-place, and as much in the ſhade as poſſible, that neither the fire nor ſun may effect it, and only raiſed by the air of the houſe; ſupporting always ſuch a ſtate of heat, as to raiſe the ſpirit in the tube to the degree marked *ananas*, the ſtandard for pine-apple Stoves, not exceeding five or ten degrees under or over that ſtandard; which thermometers are certain guides to regulate the proper growing heat requiſite for the culture of Stove exotics in this country.

There are hardly any exotics from the hotteſt parts of the world, either woody, herbaceous, or ſucculents, but may be cultivated in this kind of Stove (Bark-ſtove) by placing them in different ſituations as their natures may require; and many ſorts of hardy plants, forwarded in growth, both eſculents, flowers, and fruits.

In the arrangement of the plants in this Stove, ſome require the bark-bed, others ſucceed in any part of the houſe; and others, ſuch as the ſucculents, require the drieſt ſituation near the flues: all the more tender, herbaceous, and ſhrubby plants, natives of the hotteſt countries generally ſucceed beſt plunged in the bark bed; ſuch as the *ananas*, or pine apple; *anacardium*, or caſhew-nut; cocoa-nut tree, and many others: though many ſorts, both herbaceous and woody, ſucceed well enough in any part of the Bark Stove; and moſt of the ſucculents particularly, may be ſtationed moſtly on the top of the flues or ſhelves out of the way of moiſture, as being of themſelves naturally very replete with humidity. And as to many hardy plants deſigned for forcing, ſuch as ſtrawberries, kidney beans, and various ſorts of flowers, &c. that being potted, may be placed upon ſhelves, or on the parapet wall of the bark-bed; but the nearer the glaſſes

the better, particularly the ſtrawberries; but may raiſe good early kidney beans in almoſt any part of the Stove; though when intended to forward any ſort of flowers, ſuch as roſes, pinks, &c. or any bulbous flowers as early as poſſible, may plunge ſome in the bark-bed, the others placed upon ſhelves, &c. will ſucceed them: thus in this kind of Stove, beſides its uſe for raiſing pines and other tender plants, may forward numerous hardy plants both for uſe and curioſity.

DRY STOVE.

This is called a Dry Stove, becauſe it is furniſhed only with flues for fires and no bark-bed; and conſequently produces a more dry heat in the air within, than the bark Stoves; intended however, principally for the culture of ſome very ſucculent tender exotics of parched ſoils, that require to be kept always dry; though this was the firſt invented Stove for general uſe, before the uſe of bark-beds was introduced and brought to ſuch perfection in Stoves, where, by their moderate, durable, moiſt heat we are able to cultivate moſt ſorts of tender exotics generally in greater perfection than in dry Stoves; in which by the conſtant fire-heat all winter, night and day the fibres of the roots are ſubject to dry too faſt, and prove injurious to many ſorts of plants that are not of the very ſucculent tribe; however, ſome perſons who cultivate full collections of exotics, erect dry Stoves in which to depoſite the moſt ſucculent plants ſeparate, for fear the other plants which perſpire more freely, ſhould occaſion a damp air in winter, and be imbibed by the ſucculents, and injure them, as being impatient of moiſture in that ſeaſon particularly.

In this kind of Stove ſome moveable ſtands, or ſhelves are erected above one another, theatre-ways, on which to place the pots of plants, ſuch as the tenderer ſorts of aloes, cereuſſes, euphorbiums, melon-thiſtle, and other very tender ſucculent plants, &c.

FORCING STOVE,

Is intended principally for forcing various ſorts of hardy flowers and fruits, &c. to early perfection; ſome Forcing Stoves being deſigned entirely for flowers, as is common about London, to force large quantities of early roſes, pinks, and numerous other flowers for Covent-Garden market, where they fetch a very great price at an early ſeaſon. Other forcing Stoves are intended principally for fruit-trees, and ſome ſerve both for forcing flowers and fruits; ſo that theſe forcing Stoves conſiſt of two kinds, viz. a bark Forcing Stove being furniſhed both with a bark-bed and flues; a fire Forcing Stove having only flues for fires and no bark-bed.

The former of which, the bark Forcing Stove, is conſtructed like a common bark Stove already deſcribed, being furniſhed with a pit for a bark-bed to receive the pots of flower-plants intended for forcing, and with flues for fire-heat occaſionally; and ſometimes is formed capacious enough in width to admit of a border of earth behind the bark-bed next the back wall; ſometimes alſo, a ſmall one in front, both of which ſerving for fruit-trees, to be planted in the full ground; ſuch as cherries, peaches, apricots, &c. for early forcing; and the bark-bed is for receiving various ſorts of flower plants in pots in winter, for forcing into bloom early in ſpring; ſuch as the fineſt roſes, honeyſuckles, pinks, narciſſus, early tulips, and other flower plants, both ſhrubby, herbaceous, and bulbous, that may be required early in flower; alſo may forward any curious tender annual flowers in the bark-bed, ſuch as balſamines, &c. likewiſe may have pots of ſtrawberries, dwarf cherries, and other ſmall fruits plunged either in the bark bed, or placed any where towards the glaſſes; alſo pots or boxes of kidney-beans, ſallading, &c.

Obſerving, the ſeaſon to begin forcing or fire-working this Stove, is principally from about Chriſtmas to Candlemas, according to the earlineſs the flowers and fruits may be required; having the plants intended for forcing, previouſly potted either in the preceding ſpring or autumn, and in winter ſheltered from ſevere froſt till the forcing time arrives; but the ſhrub and tree kinds in particular, if potted the former year, to be well rooted and eſtabliſhed in the pots will be an advantage; remarking, the fruit-trees ſhould all be previouſly trained in the open ground to a bearing ſtate; then thoſe intended for the borders of earth behind the bark-pit, &c. may be planted fully therein early in autumn, without being potted; ſome of which, ſuch as peaches, nectarines, apricots, &c. to be there trained as wall-trees, others as low ſtandards, particularly cherries. And vines planted alſo againſt the front without-ſide, may be trained in; as directed below in the fire Forcing Stove.

That

That therefore, the forcing ſeaſon being arrived; having previouſly prepared the bark-bed accordingly, and plunged the plants you intend therein, alſo many ſmall kinds, ſuch as pinks, ſtrawberries, and any other low flower plants, &c. in pots placed upon ſhelves near the front and top glaſſes; and the fruit-trees being ſome in pots, placed any where the moſt convenient, others planted fully in the borders, if any; they will all ſoon be ſet in motion by the bark-bed heat; afterwards begin alſo making moderate fires on cold nights, likewiſe on days occaſionally, in very ſevere weather, to ſupport a conſtant proper warmth to continue the plants always in growth moderately; and thus may obtain various flowers and fruits two or three months before their natural ſeaſon in the open air.

The other kind of Forcing Stove, worked by fire-heat only, is furniſhed with flues and no bark-bed, but otherwiſe conſtructed like any other common Stove, having flues all round the inſide walls for fire-heat; and is deſigned principally for forcing fruit-trees, having the whole bottom ſpace within formed of good rich earth full two feet deep, in order to plant the fruit-trees entirely in the ground to remain; an alley or walk being either formed next the back wall, or carried along the middle, or continued quite round the back and front, allotting a ſmall border however cloſe along the back and front, for the reception of the choicer fruits to be trained as wall-trees; and the main middle ſpace for ſtandards of moderate growth.

Here may be planted for forcing, the beſt ſorts of apricots, peaches, nectarines, cherries, plums, vines, and figs; likewiſe, any ſmall fruit-plants, as gooſeberries, currants, raſpberries; alſo tufts of ſtrawberries. All of which being firſt trained in the open ground to a bearing ſtate.

For in this kind of Stove, having the whole bottom ſpace formed of good rich earth as before obſerved, it admits of planting the trees, in the full ground; peaches, nectarines, apricots, grapes, and figs principally againſt the back wall and front, and trained to a trellis as wall-trees; others, ſuch as cherries, are planted as ſtandards, both moderate full ſtandards, half ſtandards, and dwarfs, ranged in lines from the back to the front, the talleſt behind, and the loweſt forward; and between them may have ſmaller plants, planted alſo in the ground; alſo pots of ſtrawberries and low flowers, upon ſhelves near the glaſſes: and vines being alſo planted without ſide, cloſe againſt the front wall, are drawn in through a ſmall hole made for each, either in the wall, or in the timber of the front erections; and the branches within are trained up to the inſide of the ſlope glaſs upon trellis work, where they often produce abundance of fine fruit at an early time.

This kind of Stove is worked entirely by fire-heat, and the ſeaſon to begin forcing or make the fires, is January or early in February, continuing it moderately every night during the cold weather in winter and ſpring, to forward the different fruits to as early perfection as poſſible.

Some other ſort of forcing Stoves for fruit-trees, are contrived alſo with a low pit for a bark or dung hot-bed, or dung and bark together; beginning firſt to force the trees moderately with only the hot-bed heat; afterwards, gradually apply the fire-heat on nights, encreaſing its ſtrength by degrees.

In all theſe kind of forcing frames, every ſummer after their trees have yielded their produce, the top glaſſes ſhould be removed to admit the free air, ſhowers, &c. to ſtrengthen and harden the ſhoots of the year properly, and ſhould remain open until winter; but for more particulars in reſpect to forcing fruit-trees, ſee the article FORCING FRAME.

*The different ſtructures of Stoves.*

Stoves for the various purpoſes above noted, are formed upon different plans, according to the fancy of the owner or inventor; though there is only one good plan we would recommend for general uſe.

We formerly noticed that Stoves are for the general part ranged lengthways nearly eaſt and weſt, that the glaſſes of the front and roof may be full upon the ſun; this will be found to be the moſt convenient and eligible plan for a common Stove for general uſe, for the purpoſes before mentioned, either for a common bark Stove for pines and other exotics; a dry Stove, or any kind of forcing Stove.

There are however, Stoves of late inventions erected on the following plans.

Some, inſtead of ranging lengthways eaſt and weſt, are ranged directly ſouth and north, having a double ſloped glaſs roof, being ſloped to each ſide like the roof of an houſe, ſloped alſo at the front or ſouth end; both

both ſides and the front end being of glaſs; which kind of Stove, as to dimenſions, is from twelve to ſixteen or twenty feet wide, the length at pleaſure; and from ten to twelve or fourteen feet high in the middle, both ſides nearly head height; is formed by a brick wall all round, raiſed only two or three feet on both ſides, and ſouth end; but raiſed at the north end like the gable-end of a houſe, to correſpond with the above-mentioned double ſloped glaſs roof; and upon the top of the ſide and ſouth walling, is erected the framing for the glaſs-work, which is ſometimes formed with a two feet upright, immediately on the top of the wall, and ſloped to each ſide above; and ſometimes is wholly of a continued ſlope on both ſides, immediately from the wall to the top or ridge: within, it is furniſhed either with one or two bark pits; but if of any conſiderable width, generally with two pits ranging parallel, one under each ſlope of the top glaſs; ſeparated by a two-feet path running along the middle of the Stove; may alſo be continued all round each pit; and with flues ranged along againſt the inſide walls, or round that of the pit; ſometimes alſo, under the pavement of the walk or alley; the whole terminating in an upright funnel or chimney at the north end.

Other kinds of Stoves are formed entirely ſquare, having a ten or twelve foot brick wall behind; that of the front and both ſides, only two or three feet high for the ſupport of the glaſs-work, placed upright nearly the ſame height, and ſloped above on both ſides and front, alſo wholly of glaſs; and is furniſhed within with bark-pit and flues like the others.

And ſome Stoves are made ſemicircular, others entirely circular, formed with a two or three-feet brick wall ſupporting the glaſs framing, which is continued quite round; having the bark-pit alſo circular, and flues carried all round the inſide of the walling, terminating in a chimney on the northern ſide.

However, we have in general obſerved, that the common ſtraight Stoves ranging in a line nearly eaſt and weſt, with the main range of glaſs work in front and top full upon the ſouth, as before hinted, are the moſt commodious, as well as generally prove the moſt ſucceſsful in the end, take ſummer and winter, both for the culture of all kinds of Stove exotics; alſo for forcing any kinds of fruits, flowers, and eſculents; and is the plan we would recommend for general uſe: there are however, hot-houſes or Stoves of this plan of different dimenſions and conſtructions, according to the ſizes of the plants they are deſigned to contain: though the moſt general Stoves for all the aforementioned purpoſes are but of moderate height, not exceeding ten or twelve, or fourteen feet at moſt behind, and five or ſix in front, as in all common pine-apple Stoves; but ſome are built very lofty behind, perhaps twenty or thirty feet height as before obſerved, to admit of the taller exotics being placed towards the back part, and grow up to their full ſtature; but Stoves of a moderate height as above, are beſt adapted to the culture of pines and other moderate-growing plants, as well as for forcing. Very lofty Stoves require both a greater force of heat to warm the encloſed air effectually, and the glaſſes being ſo high, the plants receive leſs benefit of the ſun, and are apt to draw the pines, &c. up too faſt into long ſlender leaves, as they naturally aſpire towards the glaſſes as faſt as poſſible; but in lower Stoves, where the top glaſſes are but a moderate diſtance from the plants, they receive the benefit of the ſun's heat better, and do not draw ſo faſt in ſtature, but become more ſtocky at bottom, and aſſume a more robuſt firm growth, particularly the *ananas* or pine apple, and thereby more capable of producing large fruit: on which conſideration, ſuch Stoves or hot-houſes that are intended principally for the culture of the *ananas*, and other moderate exotics, and for forcing flowers, fruits, &c. ſhould never be built very lofty, but of the moderate height before obſerved, which will be found very eligible dimenſions.

It may be obſerved from the hints already exhibited, that a Stove may be large or ſmall, according to fancy or convenience; for in a ſmall or moderate ſized Stove, a perſon may indulge his fancy with a great number of the more curious ſorts of tender exotics, as well as forward many ſorts of hardy flowers and fruits to early perfection, at a moderate expence for bark and fuel; but where a more general or grander collection is required, either for pleaſure or profit, the dimenſions of the Stove muſt be enlarged proportionably; ſo that a common Stove for either, or all of the afore mentioned purpoſes, may be of any length, from fifteen or twenty, to fifty or an hundred feet, as already hinted, by

by twelve to fourteen or ſixteen feet wide; ten to fourteen feet high behind, by five or ſix in front, wall, and upright glaſs-work together, as before obſerved.—See the particulars below.

*Its General Structure, &c.*

Having however determined on the ſize or dimenſions, as to length and width, &c. of the intended Stove, the following are ſome more full and general ſketches of the dimenſions and conſtruction of the different parts of the building, ſuppoſing it is deſigned as a common bark Stove for general uſe; being furniſhed with a bark-pit and flues, &c. which may alſo ſerve as hints for the erection of any other ſort of Stove.

Proceeding therefore to ſet out the foundations of the walls accordingly of brick-work, allowing alſo due width at bottom to ſupport the flues a foot wide, wholly on the brick foundation; then ſetting off the back or north wall a brick and half or two bricks thick; and the front and end walls nine inches, carrying up the back wall from ten to fourteen feet high; but that of the front and ends only from one or two feet to a yard high, upon which to erect the upright timber framing for the perpendicular glaſſes; previouſly obſerving in carrying up the walls, to allot a proper ſpace for a door-way at one or both ends towards the back part; ſetting out alſo the furnace or fire-place of the flues near the bottom, generally towards one end of the back-wall behind, formed alſo of brick-work, and made to communicate with the lowermoſt flue within; though if a very long Stove, of more than forty feet length, a fire-place at each end will be neceſſary; or if more convenient, may have them in the back part of the end walls; in either caſe, forming them wholly on the outſide of the walls, about fourteen or ſixteen inches wide in the clear, but more in lengthways inward; the inner end terminating in a funnel to communicate internally with the flues as above obſerved; fixing an iron-barred grate at bottom to ſupport the fuel; calculated either for coal, wood, peat, turf, &c. as may be the moſt conveniently obtained; an aſh-hole being underneath, and juſt above it, is the mouth or fluel door to admit the fuel, &c. being about ten or twelve inches ſquare, having an iron frame and door fixed to ſhut with an iron latch as cloſe as poſſible; raiſing the whole furnace ſixteen or eighteen inches in the clear, finiſhing the top archways; carrying up the main walls as you go on.

Thus far obſerved, continue carrying up the walls of the building the thickneſs and height above mentioned; and within-ſide, erect the flues cloſe along the walls a foot-wide, formed with brick-work on edge, the firſt lower flue communicating with the furnace or fire-place without, and raiſed a little above it to promote the draught of heat more freely; continuing it along nearly even with the intended level of the floor of the Stove, cloſe to the wall, only eight or nine inches wide in the clear, as before obſerved, and three bricks on edge deep, returning it three or four times over one another in the back wall, and in the others, one or two as they admit, each return two bricks on edge deep; and may contrive a ſliding iron regulator to draw outward in the beginning of the firſt flues to admit more or leſs heat as may be required; being careful that the brick-work of each flue, as they proceed, is cloſely jointed with the beſt mortar, and well plaiſtered within that no ſmoke can break out, having each return cloſely covered with broad paving tiles; and the uppermoſt or laſt flue to terminate in an upright chimney at one end of the back wall; or if two ſets of flues, a chimney at each end as formerly obſerved, contriving an iron ſlider outward at the end of the laſt flue next the chimney, to confine the heat more or leſs occaſionally as required, either by the heat going off too faſt, or is become too low and weak.

Some in erecting the flues, to make the moſt of the fire-heat with as little fuel as poſſible, form one or two ſpare flues to uſe occaſionally, by means of ſliding iron regulators to admit the heat as may be required for the ſmoke to ſpend itſelf wholly in the flues before it diſcharges itſelf at the chimney; which ſpare flues are ſometimes carried along under the pavement of the floor of the walks; and ſometimes carried up againſt the outſide of the parapet wall of the bark-pit, but detached an inch or two to form a vacancy for the heat to come up without drying the bark too much.

Sometimes alſo, all the flues of ſome Stoves are built entirely detached, perhaps two or three inches from the walls, in order that the fire-heat may diffuſe itſelf from both ſides of the flue.

Should

Should be very careful, that neither the fire-place or flues is carried too near any of the wood-work, leſt it ſhould take fire.

Proceeding however within, to ſet out the cavity for the bark-pit, firſt allowing a ſpace next the flues for a two-foot path or walk all round, and then of the whole middle ſpace is formed the pit for the bark-bed, ſix or eight feet wide, the length in proportion to that of the Stove, and a yard deep; being formed by a ſurrounding wall, and may either be ſunk at bottom a foot or more in the ground, raiſing the reſt above, by means of the raiſed parapet wall; or if there is danger of wet below, it ſhould be raiſed moſtly above the general ſurface; and in either caſe, ſurrounding it wholly in width, length, and depth with a nine-inch wall; though a brick-wide wall is often made to do, eſpecially that which forms the parapet above ground; coping it all round with a timber, plate, or kirb, framed and mortiſed together, which effectually ſecures the brick-work.

Then the bottom of the pit ſhould be levelled and well rammed, and if paved with any courſe materials, it would be an advantage in preſerving the bark.

The path or alley round the pit ſhould alſo be neatly paved with brick or ſtone; this walk being very neceſſary for the convenience of performing the occaſional operations of culture, as well as to admit of walking round to view the plants and gather the produce of ſuch as yield any; though ſometimes to ſave room, the path is only continued along the back and end of the pit, having the pit continued in width quite up to the front wall, which is previouſly raiſed a little in proportion; though it is conſiderably the moſt convenient to have a walk quite round the bark-bed.

Next, in reſpect to the timber framing, and glaſs-work for encloſing the whole, conſiſting wholly of a cloſe-continued range of glaſs ſaſhes all along the front, both ends, and roof, quite to the top of the back wall; each ſaſh being a yard, or three feet ſix inches wide; and for the ſupport of which, framings of timber are erected on the brick-walling conformable to the width and length of the ſaſhes.

So that for the reception of the perpendicular glaſſes in the front and ends, a ſubſtantial timber plate is placed along the top of the front and end walls, upon which is erected upright bars at eligible diſtances, framed to a plate or crown-piece above, of ſufficient height to raiſe the whole front head high, both ends correſponding with the front and back; a plate of timber being alſo framed into the top of the back wall, to receive the ſloping bars from the frame-work in front; proper grooves or channels being formed in the front plates below and above, to receive the perpendicular ſaſhes, ſliding cloſe againſt the outſide of the uprights all the way along the front, or may be contrived for only every other ſaſh to ſlide one beſide the other, as may be convenient, for admitting freſh air, &c.

From the top of the upright framing in front, are carried ſubſtantial croſs bars or bearers ſloping to the top of the back wall, where being alſo a timber-plate, are framed at both ends to the wood-work at due diſtances, to receive and ſupport the ſlope glaſſes of the roof, ranging generally in two or more tiers, ſliding one over the other, of ſufficient length to reach quite from the top of the upright framing in front, to the top of the back wall: the croſs bars being grooved for the ſaſhes to ſlide up and down occaſionally over one another, making the upper end of the top tier of glaſſes, ſhut cloſe up to the plate in the wall behind, running under a proper coping of wood or lead, fixed along above cloſe to the wall, and lapped down of due width to cover, and ſhoot off the wet ſufficiently from the upper termination of the ſaid top ſaſhes; though ſome very wide Stoves, excluſive of the main ſlope ſliding glaſſes, have a ſhorter upper tier of glaſs always fixed in the ſame place; the upper ends cloſe to the back wall ſecured under a coping as above, and the lower ends lapping over the top ends of the upper ſliding tier, and this over that below in the ſame manner, to ſhoot the wet clear over each upper end or termination; likewiſe along the under outer edge of the top plate, or crown-piece in front, may be a ſmall channel to receive the water from the ſlope glaſſes, and convey it to one or both ends without running down upon the upright ſaſhes; being careful that the top of all behind is well framed and ſecured water-tight, and finiſh the top of the back wall with a neat coping the whole length.

In every part, the bars of wood which ſupport the glaſſes ſhould be neatly formed, neither made very broad nor thick to intercept the rays of the ſun; making thoſe however at top ſtrong enough to ſupport the glaſſes without bending under them.

The

The glazing of the ſaſhes ſhould generally be in the imbricated manner, more eſpecially the ſlope ſaſhes of the roof; ſo that the panes of glaſs ſhould be laid in putty, with the ends lapping over each other about half an inch; the vacancies of which are by ſome cloſed up at bottom with putty, others leave each lapping of the panes open, in order both for the air to enter moderately between the ſquares of glaſs, and likewiſe that the rancid vapours ariſing from the fermentation of the bark-bed, &c. within, may be kept in conſtant motion without condenſing much; and that ſuch as condenſe againſt the glaſſes, may diſcharge itſelf at thoſe places without dropping upon the plants; but as to the upright ſaſhes in front, they may be either glazed as above, or the panes laid in lead work; being very careful in both places to have the glazing well performed proof againſt wet.

A door way for general entrance having been formed at one end of the building near the back wall, the door of which may either be wholly of wood, or the upper half may be ſaſhed and glazed to correſpond with the other adjoining glaſs-work of the ends.

Within-ſide of the building, the walls ſhould be plaiſtered, pargetered, and white-waſhed; and all the wood-work, both within and without, painted white in oil colour for its preſervation, and to give the whole a lively appearance, as well as to reflect the rays of light upon the plants on nights, which is ſuppoſed proves of ſome importance in improving their growth.

As to any neceſſary internal erections, there may be one or two ranges of ſhelves for pots of ſmall plants, erected near the top glaſſes towards the back part, ſupported either by brackets ſuſpended from the croſs bars, or by uprights erected on the parapet wall of the bark-pit: a range or two of narrow ſhelves may alſo be placed occaſionally along the front-glaſſes, and both ends; all of which ſhelves will ſerve for holding pots of many ſorts of ſmall plants, that do not require to be plunged in the bark-bed; alſo for pots or boxes of ſtrawberries, cucumbers, flowers, &c. in winter, and early in ſpring for forcing; which being placed as near the glaſſes as poſſible, are generally the moſt proſperous and ſucceſsful in their reſpective crops.

In very wide Stoves, if the croſs bars or bearers of the ſlope or top glaſſes appear to want ſupport, ſome neat uprights either of wood or iron, may be erected upon the bark-bed walling, at convenient diſtances, and high enough to reach the bearers above, and ſupport them effectually in their proper poſition without bending under the glaſſes.

Without-ſide of the Stove over each fire-place, ſhould generally be erected a ſmall covered ſhed with a door to ſhut, for the convenience of attending the fires, and keeping them regularly burning.

Or if the ſituation admitted, a cloſe ſhed might be erected all the way againſt the north ſide of the back wall, which will defend the back of the Stove from the outward air; and if the fire places are behind, it will be convenient for attending and preſerving the fires as aforeſaid; ſerving alſo to ſtow fuel for the general uſe of the Stove, alſo for garden tools, and all garden utenſils when not in uſe, to preſerve them from the weather.

It is likewiſe of importance to have covers for the glaſſes, to draw over occaſionally in ſevere froſts and hail ſtorms, more particularly the top ſaſhes; for which purpoſe ſome uſe wooden, or canvas ſliding ſhutters fitted to the width, &c. of the frames of the ſaſhes ſo as to ſlide on and off preſently; others uſe rollers of painted canvas or tarpaulin rolled up on long poles or rollers, and fixed lengthways all along the top of the Stove juſt above the upper ends of the top ſaſhes; which, by means of lines and pullies, are let down all at once in a minute, and by the ſame means are rolled up again almoſt as expeditiouſly: ſome Stoves however, have neither ſhutters nor rollers for covering; uſing only either large baſs mats or reed mats occaſionally for the ſlope glaſſes, eſpecially in ſevere froſts; though it is alſo proper to defend the upright glaſſes on nights particularly, in very rigorous weather.

Thus far is principally all we have to ſay concerning the general ſtructure of a bark Stove, which may ſerve to convey ſome neceſſary hints, both for the erecting of this, and any other ſort of Stove; and as moſt builders are now well acquainted with the general plan, by giving the intended dimenſions as to ſize, &c. to the different workmen concerned, ſuch as bricklayers, carpenters, and glaziers, they can readily execute it, and finiſh the whole completely, as in other buildings.

The above kind of Stove is calculated not only as a pinery for the culture of the

pine-apple, but for all ſorts of tender exotics of ſimilar quality; ſome requiring to be plunged in the bark-bed, others placed on the top of the flues and ſhelves, and others nearer the glaſſes: the ſame Stove ſerves alſo to force fruits, and flowers, &c. as already hinted.—See STOVE PLANTS.

Remark however, that ſuch Stoves as are intended principally for pine-apples, and for forcing flowers, ſtrawberries, dwarf fruit-trees, and ſmall culinary eſculents, &c. may be only ten feet high behind, and which generally ſucceed better for theſe plants than ſtoves of more lofty dimenſions, for the reaſons already obſerved.

Likewiſe, by raiſing the bark-pit within wholly above the ſurface, elevates the plants plunged therein nearer the glaſſes, and proves advantageous in their growth.

In erecting Stoves, to ſave ſome expence, any garden-wall already built in an eligible expoſure may be made to ſerve as the back wall to the building.

*Nurſery and Succeſſion Stove.*

Beſides the main bark Stove above deſcribed, it is very convenient to have one or two ſmaller, as a nurſery-pit, and a ſucceſſion Stove, particularly where large collections are required, and more eſpecially in the culture of large quantities of pine apples; one ſerving as a nurſery-pit, in which to ſtrike and nurſe the young off-ſpring crowns, and ſuckers of the old pines for propagation; the other as a ſucceſſion-houſe for receiving the year old plants from the nurſery-pit, and forwarding them a year to a proper ſize for fruiting, as ſucceſſion plants, to furniſh the main Stove or fruiting-houſe every autumn, to ſucceed the old plants then done fruiting.

Theſe ſmaller Stove departments prove materially uſeful in the culture of pines, particularly to raiſe and nurſe the young plants, until arrived to a proper age and ſize to produce fruit; then moved into the main Stove or fruiting-houſe, which being thus ſupplied from theſe ſmaller Stoves, with a ſucceſſion of fruiting plants annually, without being crowded or incommoded with the rearing of the ſaid ſucceſſion plants, proves a particular advantage, not only in the culture of the fruiting plants, as they often require a higher degree of heat than the ſucceſſion plants at particular times, in order to forward and improve the growth of fruit properly; but it is alſo making the beſt advantage of this main department, to have the bark-bed always filled with fruiting plants only, producing a full crop of proper ſized pine-apples every year, which could not always be effected with ſuch certainty and perfection without the aid of theſe ſucceſſion Stoves; becauſe the pine-plants in their infant ſtate require ſometimes different management from the fruiting plants, particularly in reſpect to the degree of fire-heat as aboveſaid, which in general ſhould be more moderate than for the fruiting plants, leſt too much heat force them into fruit in their minor growth, when incapable of producing it in any tolerable perfection.

Therefore, theſe ſmaller ſucceſſion Stoves may be erected as appendages to the main houſe, or may be detached at ſome diſtance as may be convenient; though if the ſituation admits, it may be both more convenient and ornamental to join them in a line with the main Stove, one at each end, and nearly of the ſame conſtruction; but may be ſmaller, both in length, width, and height, if thought proper; and ſometimes for cheapneſs, are formed without any upright glaſſes in front, having a wall all round, five or ſix feet; behind gradually ſloping at each end, to three or four in front; and with only ſliding glaſſes at top, more particularly the nurſery Stove, commonly called ſimply the pit, becauſe the whole internal ſpace in length and width, is often allotted intirely as a pit for a bark-bed, frequently without any walk within, or door for entrance; the neceſſary culture being performed by ſliding open the glaſſes at top, and the flues for the fires being formed in the upper part of the back wall: however, it may be more eligible to form the ſucceſſion Stove particularly, nearly like the main one, with erect glaſſes in front, and ſloping ſaſhes at top, with a door for entrance, and an alley or walk next the back wall at leaſt.

Obſerving however, if theſe ſmaller Stoves are joined to the end of the main one, they may be divided from it only by a ſliding glaſs partition for communication with each other, particularly the ſucceſſion and main Stove; but with ſeparate furnaces, and flues to each department; becauſe the young pine plants do not at all times require the ſame degree of fire-heat as the older pines, eſpecially thoſe of proper ſize for fruiting; ſo that

that by having ſeparate fires, the heat can be regulated accordingly.

The nurſery Stove or pit, may be of ſmaller dimenſions in reſpect to width and height, than the ſucceſſion houſe, if thought convenient: and if deſigned wholly as a pit without any path or walk within, ſix or eight feet width may be ſufficient, by five or ſix high in the back wall, and four in front, the whole internal ſpace being filled with tan three feet, deep to form the bark-bed: ſerving chiefly as a nurſery in which to ſtrike and nurſe the annual encreaſe of crowns and ſuckers, of the *ananas* or pine-plants the firſt year; alſo to raiſe many tender plants from ſeeds, cuttings, &c. without incumbering the main Stove; and when they are forwarded to ſuch a ſtate of growth as to require more room, they are removed to the ſucceſſion-houſe.

But the ſucceſſion-houſe may be nearly on the plan of the main Stove, though of ſmaller dimenſions both in width and height; and is intended to receive the year-old pine-plants from the pit or nurſery Stove, in order to plunge them at greater diſtances, ſufficient to give the whole proper ſcope to take their full growth another year, when they will generally be arrived to a proper ſize for fruiting the year following; being previouſly removed in autumn to the main fruiting Stove to ſucceed the old fruiting plants, which generally by October have all yielded their produce, are then removed away, and their place ſupplied by a ſufficient quantity of large plants from the ſucceſſion houſe, being arrived to a proper ſtate of growth to produce fruit next ſummer: and the ſucceſſion-houſe is at the ſame time repleniſhed with the largeſt plants from the nurſery pit, which next autumn will probably be alſo arrived to a proper ſize for removing to the fruiting-houſe to ſucceed the others.

Thus by having the different Stove departments always furniſhed with pine plants of three different ſtages of growth, ſucceeding one another regularly, i. e. the nurſery pit containing the yearly crowns and ſuckers, the ſucceſſion pit the one and two-year plants, and the main Stove the fruiting plants, a conſtant ſucceſſion of fruiting plants is thereby annually obtained; for the ſame individual plants never produce fruit but once; they however, produce a plentiful ſupply of crowns and ſuckers which commence proper plants, attaining a fruiting ſtate in regular ſucceſſion.

However, in many places the ſituation or convenience not admitting but of one common Stove to raiſe and forward the pines and other exotics, in their different ſtages of growth, or at leaſt with probably the aſſiſtance only of a ſmall detached bark-pit, or a bark and dung hot-bed under a large garden frame, to ſtrike and nurſe the yearling crowns and ſuckers of the pines, &c. of each year, until they are about a year old, then moved into the Stove: yet with proper care and ingenuity often produce very good pine apples, as well as raiſe many other curious exotics, and forward flowers to early bloom; alſo early fruit and ſome culinary eſculents.

But having a main Stove with two ſmaller ones adjoining, nearly on the ſame plan as above hinted, we can always with greater certainty, obtain a regular annual ſucceſſion of fruiting pines in perfection.

Remarking, that in all theſe Stoves there may, beſides pine apples which generally occupy the bark-bed, either wholly or in part, be retained numerous other tender curious exotics from the hot parts of the world, that require aid of a hot-houſe in this country; ſome placed in the bark-bed as their nature may require, others upon the top of the flues, top of the bark-pit wall, and upon ſhelves; all of which is generally hinted in the culture of the reſpective ſorts, a liſt of which is exhibited below, being collected into one point of view under the head *Stove Plants*; ſhewing at once all the principal Stove or hot-houſe plants, from the hot parts of Africa, Aſia, and America, now inhabitants of the Engliſh gardens; with hints for their general culture, referring to their proper genera for particulars; likewiſe, a liſt of ſuch hardy flowers, fruits, and culinary eſculents, as may be forwarded to early perfection by the aſſiſtance of theſe departments.

Suppoſing however, the Stove or Stoves are now erected, and ready for the reception of the various plants intended; then obſerving of the bark Stove, that preparations muſt be made early in autumn, to fill the bark-pit thereof with tanner's bark to form the bark hot-bed, for the immediate reception of the tenderer kinds of plants, to be plunged therein, each in its proper pot; this kind of hot-bed being the moſt eligible for all kinds of Stoves or hot-houſes, as by its moderate and durable fermentation, no

material yet known equals it for a hot-bed; it effecting a uniform laſting heat, of a temperature peculiarly adapted to the growth of pine-apples, and many other tender exotics of ſimilar quality. — See BARK BED.

The autumn, about September or early part of October, is the general ſeaſon for filling or repleniſhing the bark-pit with freſh bark or tan, that the bed may ſupport a conſtant lively heat during the winter: however, the work may alſo be performed occaſionally in ſpring, or any time of the year, as occaſion may require.

But for the general management of the Stove or hot-houſe, and the plants thereof, ſee STOVE PLANTS below; in the article of their *General Culture.*

### STOVE PLANTS.

Having exhibited in the foregoing head general hints of the form, dimenſions, and conſtruction of the different ſorts of Stoves, and their reſpective uſes in the culture of plants, we now proceed to a liſt of all the principal Stove plants, or ſuch tender exotics from the hot parts of the world, that require the aid of a Stove to preſerve them in this country; and although they are ſeparately and fully treated of under their reſpective genera, yet by collecting them under one point of view in this place, each under its generical name, with ſhort hints of their nature, by diſtinguiſhing which are ſhrubby, herbaceous, and ſucculent, will, we preſume, aſſiſt the memory in making a collection; referring to their reſpective genera, for the particulars of their reſpective deſcription and culture.

ACANTHUS, Bear's-breech. — Shrubby, holly-leaved *Acanthus.* (*Underſhrubby.*)

ACHRAS, Sapota or Mammee-tree.--Common Sapota.—Mammee Sapota. (*Trees.*)

ACHYRANTHES, Bloody or Red Indian *Achyranthes.*—Woolly-cupped Indian *Achyranthes.*—Lapaceous or Bur-flowered Indian *Achyranthes.*—Prickly-cupped ſhrubby Indian *Achyranthes.*—(*Moſtly herbaceous, and the laſt ſhrubby.*)

ADANSONIA, Æthiopian Sour Gourd. (*Tree.*)

ADENANTHERA, Baſtard Flower Fence. —*Pavonina.*—*Falcataria.* (*Trees.*)

ÆSCHYNOMENE, Baſtard Senſitive plant. —Tree *Æſchynomene.*—Grandiflorous *Æſchynomene.*—Seſban, or Ægyptian *Æſchynomene.* (*Woody.*)

AGAVE, American Aloe.—Viviparous American Aloe.—Stinking American Aloe. (*Succulents.*)

ALETRIS, Guinea Aloe. — Hyacinth-flowered *Aletris.*—Ceylon *Aletris.*—Cape *Aletris.*—Fragrant *Aletris.* (*Succulents.*)

ALOE, African Aloe. Moſt of the ſpecies, except the *Aloe Uvaria*, may be conſidered both as green-houſe and Stove plants; for, although they may all be wintered tolerably well in a green-houſe, yet if placed in the Stove, in winter particularly, they more certainly flower annually in greater perfection. (*Succulent.*)

AMARYLLIS, Lily Daffodil.—Jacobæan Lily.—Mexican Lily.—Zelon Lily. (*Herbaceous and Bulbous.*)

AMOMUM, Ginger.—Common Ginger. Broad-leaved wild Ginger, &c. (*Herbaceous*).

ANACARDIUM, Acajou or Caſhew-nut. (*Tree.*)

ANNONA, Cuſtard-apple.—Netted Cuſtard apple. — Prickly Cuſtard apple. — Scaley Cuſtard apple, or Sweet Sop.—Marſh *Annona*, or Water apple.—Broad-leaved *Annona.* (*Tree and Shrub kinds.*)

APOCYNUM, Dog's-bane.—Shrubby upright Ceylon *Apocynum*, with varieties.—Climbing Dog's-bane, with varieties.—(*Shrubby.*)

ARUM, Wake-Robin, &c. — Ægyptian *Arum* or Colocaſia.—Trilobate Indian *Arum.*—Tree *Arum.*—(*Two firſt herbaceous, the other ſomewhat ligneous.*)

ARUNDO, Reed.—Bamboo Cane, or Indian tree-Reed. (*Ligneous.*)

ASCLEPIAS, Swallow-wort. — American Scarlet *Aſclepias*, &c.—(*Herbaceous but ligneous ſtalked.*)

ASPARAGUS, Sparagraſs.—Tree *aſparagus*, or Dragon-tree. (*Woody.*)

BARLERIA, ſeveral Species. (*Herbaceous and Shrubby.*)

BASELLA, Malabar Nightſhade.—Red Malabar Nightſhade. — White Malabar Nightſhade. (*Herbaceous.*)

BAUHINIA, Mountain Ebony.—Prickly *Bauhinia.*—Tomentoſe *Bauhinia.* (*Shrubby.*

BIGNONIA, Trumpet-flower. — Several ſpecies. (*Chiefly Woody.*)

BIXA, Dying Metella, &c. (*Shrubby.*)

BOCCONIA, Tree-celandine. (*Shrubby.*)

BOMBAX, Silk Cotton-tree. — Thorny *Bombax*, or Ceiba.—Pentandrous, ſmooth *Bom-*

*Bombax.* — Heptaphyllous ſmooth *Bombax.* (*Trees.*)

BONTIA, Barbadoes Wild Olive. (*Shrubby.*)

BROMELIA, *Ananas*, Pine-apple.—Common *Ananas* or Pine-apple. — Wild Pine-apple or Pinguin. — *Karatas*, or Acaulous wild Pine-apple. — Pyramidal *Bromelia.*— Lingulated *Bromelia.* (*Herbaceous.*)

BRUNSFELSIA, *Brunsfelſia.* (*Shrubby.*)

BUDDLEJA, American *Buddleja.* — Occidental *Buddleja.* (*Shrubby.*)

CACTUS, Melon-thiſtle, Torch-thiſtle, &c. — Greater Hedge-hog Melon-thiſtle, with Varieties.— Mammillary, or Smaller Melon-thiſtle. — Torch thiſtle, ſeveral upright ſorts. — Creeping or trailing Torch-thiſtle. — Climbling Torch-thiſtle. — *Ficus Indica*, or Indian Fig.—Greater Indian Fig. —Cochineal Indian Fig. — Indian Fig of Curaſſoa.—Sword-leaved *Opuntia.* — *Periſkia*, or American Gooſeberry. (*All of the Succulent tribe.*)

CAPSICUM, Guinea-Pepper. — Shrubby *Capſicum*, with many varieties. (*Shrubby.*)

CARICA, Papaw or Pepo-tree. — Common Indian Papaw-tree. — Poſopoſa, or Branching Surinam Papaw-tree. (*Tree like.*)

CASSIA, Wild Sena.—Purging-tree *Caſſia.*—Biflorous ſhrub *Caſſia.* (*Tree and Shrub kinds.*)

CATESBEA, Lily-thorn. (*Shrubby.*)

CEANOTHUS, New Jerſey Tea.—Aſiatic *Ceanothus.* (*Shrubby.*)

CESTRUM, Baſtard Jaſmine, or Jaſminoide.—Nocturnal *Ceſtrum.*— Diurnal *Ceſtrum.* (*Shrubby.*)

CHAMÆROPS, Dwarf Palm or *Palmetto.* (*Frondoſe.*)

CITHAREXYLON, Fiddle Wood. (*Shrubby.*)

CLUTIA, *Elutaria*, or Indian *Clutia.* (*Shrubby.*)

COCOS, Cocoa-nut-tree. (*Frondoſe Tree-kind.*)

COFFEA, Coffee-tree. (*Shrub-like.*)

COTYLEDON, Navel-wort.—Cut or jagged-leaved *Cotyledon.* (*Succulent.*)

CRESCENTIA, Calabaſh-tree. (*Tree kind.*)

CRINUM, Aſphodel-lily.—American Aſphodel-lily.—Aſiatic Aſphodel-lily. (*Bulbous herbaceous plants.*)

ELÆAGNUS, Wild Olive, or *Oleaſter.*— Thorny *Elæagnus.* (*Woody.*)

ERYTHRINA, Coral-tree.—*Corallodendron*, or Smooth Coral-tree.—Spinous Coral-tree.—Herbaceous *Erythrina.* (*Shrubby and Herbaceous.*)

EUPHORBIA, Burning Thorny Plant.— *Euphorbia* of the Ancients.—Canary *Euphorbia.* —Oleander-leaved *Euphorbia.* — Meduſa's-Head *Euphorbia.*—Tithymaloide *Euphorbia*, or Baſtard Spurge. (*All Succulent.*)

FICUS, Fig tree.—Sacred Fig, or Indian God-tree.—Sycamore Fig-tree.—Bengal Fig-tree.—Indian long-leaved Fig-tree.—Dwarf Indian Fig-tree. (*Tree kinds.*)

GARDENIA, Cape Jaſmine. (*Shrubby.*)

GLORIOSA, Superb Lily. (*Herbaceous*).

GOSSYPIUM, Cotton-plant.—Conſiſts of herbaceous and ſhrubby ſpecies. See GOSSYPIUM.

GREWIA, Oriental *Grewia.* (*Shrubby.*)

HÆMANTHUS, Blood-flower. — Scarlet *Hæmanthus.*—Reddiſh *Hæmanthus.* —Carinated *Hæmanthus.*—Ciliated *Hæmanthus.* (*Herbaceous bulbs.*)

HÆMATOXYLUM, Blood-wood, or Log-wood. (*Tree-like.*)

HERNANDIA, Jack-in-a-box-tree. — Sonorous *Hernandia.* — Oriental *Hernandia.* (*Trees.*)

HIBISCUS, Syrian Mallow. — Mutable-flowered *Hibiſcus*, or China Roſe.—*Roſa Sinenſis*, or Roſe of China.—Viſcous Mallow, or Scarlet *Hibiſcus.* (*Shrubby.*)

HURA, Sand Box-tree. (*Woody.*)

IATROPHA, Caſſada, or Caſſava Plant.— Moſt of the ſpecies are Stove-plants. (*Woody and herbaceous.*)

JUSTICIA, Malabar-nut. —Hyſſop-leaved Juſticia, &c. (*Woody.*)

KÆMPFERIA, *Galangale.*—Both the ſpecies (*Herbaceous.*)

LANTANA, American Viburnum. —Trifoliate *Lantana.*—Involucrum-headed *Lantana.*—*Camara*, or leafleſs-headed *Lantana.*— Prickly *Lantana.* (*Shrubby.*)

LOBELIA, Cardinal flower. — Plumier's *Lobelia.*—Surinam *Lobelia.*—Pine-leaved *Lobelia.* (*Shrubby.*)

MALPIGHIA, Barbadoes Cherry. — All the ſpecies. (*Woody.*)

MAMMEA, Mammee-tree. — American Mammee tree. — Aſiatic Mammee Tree. (*Trees.*)

MARANTA, Indian Arrow-root. — Arundinaceous *Maranta.* — Galanga, or Indian Arrow-root. (*Herbaceous.*)

MARTYNIA.—Perennial *Martynia.* (*Herbaceous.*)

MELIA, Bead-tree.—Evergreen Bead-tree of Ceylon.—*Azadirachta*, or Indian Bead-tree. (*Tree kinds.*)

MESEMBRYANTHEMUM, (*Ficoides*) Fig Marigold.—Diamond *Ficoides*, or Ice-plant. (*Herbaceous and Succulent.*)

MIMOSA, Senſitive plant.—All the ſpecies. (*Shrubby and Herbaceous.*)

MUSA, Plantain-tree. — All the three ſpecies. (*Of a Tree-like growth, but Herbaceous nature.*)

MYRTUS, Myrtle-tree.—Pimento or All-ſpice-tree. — Dioecious Myrtle. — Braſilian Myrtle, &c.—(*Tree and Shrub kinds.*)

NERIUM, Oleander. — Double-flowered. —Striped-leaved, &c. (*Shrubby.*)

NYCTANTHES, Arabian Jaſmine.—Sambac, or Common Arabian Jaſmine.—Undulate-leaved *Nyctanthes*, or Malabar Jaſmine. —*Arbor Triſtis*, or Sorrowful-tree.—Hairy Sorrowful-tree. (*Shrubby.*)

PANCRATIUM, (*Pancratium* lily) Sea Daffodil. — Ceylon uniflorous *Pancratium.* — Mexican biflorous *Pancratium.* — Caribbæan multiflorous *Pancratium*—Carolina multiflorous *Pancratium.* — Amboyna broad-leaved *Pancratium.* (*Bulbous Herbaceous perennials.*)

PASSIFLORA, Paſſion-flower. — Sawed-leaved Paſſion-flower.—Laurus-leaved Paſſion-flower.—Veſpertilious, or Bat's wing Paſſion-flower.—Red Paſſion flower.—Maliformous, or apple-fruited Paſſion-flower.—Silky Paſſion-flower.—Multiflorous Paſſion-flower. — Quadrangular Paſſion-flower. — Suberoſous, or Cork-barked Paſſion-flower. (*Woody, and Herbaceous climbers.*)

PERIPLOCA, Virginia Silk, &c.—Indian *Periploca.* (*Woody.*)

PHOENIX, Great Palm, or Date-tree. (*Ligneous.*)

PHYSALIS, Winter-cherry.— *Arboreſcent*, or Tree *Phyſalis.*—Winter-cherry of *Curaſſao.* (*Woody.*)

PLUMBAGO, Lead-wort.—Ceylon *Plumbago.*—Roſe *Plumbago.* (*Ligneous or Underſhrubby.*)

PLUMERIA, Red Jaſmine.—Red *Plumeria.*—White *Plumeria.* — Obtuſe *Plumeria.* (*Woody Succulents.*)

POINCIANA, Barbadoes Flower-fence, &c. —Fair *Poinciana*, or Double-ſpined Barbadoes Flower-fence. — Bijugated Single-ſpined *Poinciana.* — Spineleſs *Poinciana.*— (*Shrubby.*)

POLYANTHES, Tuberoſe, or Indian Tuberous Hyacinth. (*Herbaceous.*)

PTELEA, Shrub trefoil.—Viſcous Indian *Ptelea.* (*Shrubby.*)

RHAMNUS, Buckthorn. — *Spina Chriſta*, or Æthiopian Jujube.—*Oenoplia*, or Ceylon Jujube. (*Shrubby.*)

RHUS, Sumach.—Cobbe, or Ceylon Sumach. (*Shrubly.*)

RIVINIA, Dwarf Tetrandrous *Rivinia.*—Climbing Octandrous *Rivinia.* (*Ligneous.*)

ROBINIA, Falſe Acacia.—Violet American *Robinia.*—Smooth Indian *Robinia.* (*Tree and Shrub kinds.*)

SACCHARUM, Sugar-cane. — Common Sugar-cane. — Spiked Sugar-cane. (*Herbaceous, of the Arundinaceous tribe.*)

SCHINUS, Indian Maſtic-tree. — Molle-tree of Cluſius, or Peruvian Maſtic-tree.—Areira, or Braſilian Maſtic-tree. (*Woody.*)

SIDEROXYLON, Iron-wood. — Inormous, or Smooth Æthiopean *Sideroxylon.*—Spinous, Malabar *Sideroxylon.* (*Shrubby.*)

SOLANUM, Nightſhade.—Guinea Nightſhade.—Fiery-thorned Nightſhade. —Bahama Nightſhade.—Trilobate Nightſhade, &c. (*Shrubby.*)

STAPELIA, Variegated *Stapelia.* — Hairy *Stapelia.* (*Succulent, and ligneous.*)

TAMARINDUS, Tamarind-tree. (*Tree.*)

THEOBROMA, Chocolate nut-tree.—*Cocao*, or Chocolate-nut-tree.—*Guazuma*, or Baſtard Cedar of Jamaica. (*Shrub and Tree kind.*)

TOLUIFERA, Balſam of Tolu-tree.

TOURNEFORTIA, Shrubby *Tournefortia.* —Volubilate, or Twining *Tournefortia.*—Fœtid, or Stinking *Tournefortia.* — Hairy *Tournefortia.* — Serrated *Tournefortia.*—Cymoſe *Tournefortia.* (*Shrubby.*)

TRIUMFETTA, *Lappula*, or *Triumfetta.* (*Ligneous.*)

TURNERIA, Elm-leaved. (*Ligneous.*)

VINCA, Periwinkle. — Roſe Periwinkle of Madagaſcar. (*Shrubby.*)

VITIS, Vine.—Indian wild Vine.—Trifoliate Indian Vine. (*Shrubby.*)

VOLKAMERIA, Prickly *Volkameria.*—Unarmed or Smooth *Volkameria.* (*Shrubby, and Underſhrubby.*)

URENA, Angular-leaved *Urena* —Sinuated *Urena.*—Procumbent *Urena.* (*Woody.*)

WALTHERIA, American *Waltheria.* Indian *Waltheria.*—Narrow-leaved *Waltheria.* (*Ligneous.*)

WINTERANIA, (*Shrubby.*)

XIMENIA, American Prickly *Ximenia.* —Unarmed Jamaica *Ximenia.* (*Trees.*)

ZAMIA,

ZAMIA, Dwarf American Palm. *(Frondoſe.)*

Of the above liſt of Stove plants, a few of the ſorts are alſo inſerted in the green-houſe liſt; becauſe, in default of a Stove, they may be preſerved tolerably well in a good green-houſe, though probably brought to greater perfection in a Stove, as is generally noticed in the culture of the reſpective ſorts, each in its proper genus.

*General Management.*

As to the general management of the bark Stove and culture of the plants; the pit of the Stove muſt always be filled with bark to produce a continual heat, making fires only in winter, &c. and all the plants muſt be kept conſtantly in pots, in order to move to different ſituations in the houſe occaſionally, ſome in the bark-bed, others on the ſhelves, top of the flues, &c.

But to prepare the Stove for the reception of the plants, the bark-bed muſt be formed by filling the pit with new tanner's bark early in autumn, or any time elſe when the moſt convenient to obtain the plants.

The bark for this purpoſe is procured from the tan-yards, after having been uſed in tanning, and caſt out of the tan-pits; chuſing that which is freſh, not having lain long to exhauſt itſelf, or become black and earthy; but the freſher it is from the tan-pits the better, preferring the larger or middling ſort to the ſmall-cut bark, which ſoon becomes earthy and declines its fermentation; but the larger ſort will retain its heat ſeveral months: having however obtained the proper quantity, it is proper, previous to committing it to the pit, to ſpread it abroad or diſpoſe it in ſmall heaps or ridges, two or three days in dry weather, to drain and dry moderately; or if copiouſly wet, may afterwards be formed into an heap to drain off the redundant moiſture more effectually, and promote its fermentation; and in a few days, or perhaps a week or more, it will be in good preparation for uſe; then fill it into the bark-pit, being careful as it is thrown in, to ſhake it up well together with the bark fork equally in every part, not beating or treading it down, raiſing the whole half a foot above the top of the pit to allow for ſettling, ſuffering it to ſettle gradually of itſelf; and thus the fermentation will come on regularly perhaps in a week or ten days; though may probably be a fortnight or more, before it becomes of a due temperature for the reception of the plants: having ſome long ſticks thruſt into the bed, drawing them up daily, and feel them with the hand, you will more eaſily diſcover the progreſs of the fermentation, and proper degree of heat; obſerving, if the heat ſhould prove violent, to defer plunging the plants till it is become of a more moderate temperature.

When therefore the bark-bed is ready, prepare to plunge the plants, ſuch as pines and other exotics that require the aid of the bark-bed; and the other leſs tender kinds, to be placed in different parts of the houſe as their nature may require; all the ſorts being previouſly planted in pots.

In potting the different kinds, allot proper ſized pots according to the ſize and nature of the plants, not too large at firſt, for as they advance in growth they may be ſhifted into others, a ſize larger, &c.

Being careful alſo, to pot them in proper earth adapted to the nature of the reſpective ſorts; though moſt of the ſhrubby or woody kinds, and the common herbaceous tribe, ſucceed in any common rich light earth; but all the ſucculent plants ſhould be planted in a dry, ſandy, or rubbiſhy ſoil, on account of their humid quality: however, as to the different ſoils requiſite for any particular ſort, it is exhibited in their culture under their reſpective heads.

In proceeding to plunge the pines and other ſorts intended in the bark-bed, it is proper to have a broad plank or board to lay acroſs the bed, on which to ſtand or kneel without treading the bark hard; likewiſe a hand-fork for opening the apertures more expeditiouſly to plunge the pots, which may be plunged to their rims, if the fermentation is not too violent; arranging the plants regularly in reſpect to their different gradation of height, the talleſt behind, gradually down to the loweſt in front; and if diſpoſed in the quincunx way, they will receive the advantage of more room, and benefit of the air and rays of the ſun more equally, plunging the whole down to the rims of the pots, as above obſerved; and at the ſame time, let all the other leſs tender kinds, be diſpoſed in different parts of the houſe, as their temperature may require: many of the woody and herbaceous kinds ſucceed well enough any where within the Stove; but moſt of the ſucculent tribe ſucceed beſt in the drieſt part near the flues, diſtant from moiſture, eſpecially in winter,

being

being placed either on the top of the flues, or on ſhelves ranged above them; though almoſt any ſorts of Stove plants when intended to forward them faſter in growth, or into bloom, may be plunged in the bark-bed occaſionally; however, as to the *ananas* or pine-apple, although they will grow in any part within the Stove out of the bark-bed, yet never ſo proſperouſly, nor produce any but ſmall trifling fruit, therefore require to be continued always plunged in the bark-bed the year round; ſeveral other of the more tender curious exotics, not ſucculents, are alſo the moſt proſperous if plunged in the bark-bed, where there is room enough without incommoding the pine-plants.

Obſerve, if after the plants are plunged in the bark-bed, the bark ſhould happen to heat violently, it is proper to draw up the pots half way, or far enough to ſave the roots of the plants from being by vehemence of the heat damaged, replunging them again down to their rims when the heat becomes more moderate.

Moſt of theſe kinds of Stove plants require to be continued almoſt conſtantly in the Stove the year round; though, if the Stove is much crowded, ſome of the leſs tender kinds will bear to be almoſt fully expoſed to the open air, ſix weeks or two months in the heat of ſummer, in warm dry ſeaſons; at leaſt, may remove ſome into the green-houſe or under frames, &c. towards the latter end of June, or beginning of July, to thin the Stove; the green-houſe being then vacant, and in which theſe hardier Stove plants may enjoy the free air more copiouſly to promote ſtrength, by opening all the windows daily, yet be ſheltered on nights and bad weather; which would change the colour of their leaves diſagreeably; removing them however, into the Stove again early in September, or as ſoon as the nights prove cold.

The Stove muſt always be kept nearly to a certain regular temperature of heat as marked on the botanical thermometer *(ananas)*; obſerving, that in ſummer from April or May until October, the bark-bed heat alone, aided by the heat of the ſun through the glaſſes, will ſufficiently warm the internal air: but from October or beginning of November, to April or May aforeſaid, the additional aſſiſtance of fire-heat is requiſite to expel the cold within, and ſupport a due warmth in the internal air, nearly equal to that in ſummer; by making fires every evening and morning in the furnace of the flues, alſo occaſionally on days in very cold damp weather, and rigorous froſts without ſun.

But, as a guide to regulate the degree of heat requiſite for Stoves, eſpecially in winter, a botanical thermometer ſhould be placed in a convenient ſituation within, not too near the fire-place or flues, but hung up towards the center of the houſe with the back to the ſun, ſo as the mercury or liquid ſpirit in the glaſs globe and tube may be affected, only by the warmth of the air internally, thereby diſcovering the real degree of heat more effectually, which ſhould always be ſo regulated, as not to exceed five or ten degrees over or under the mark *ananas*, which as we noticed before, is the ſtandard generally to be obſerved in regulating the temperature of Stove heat at all ſeaſons.—See THERMOMETER.

Freſh air muſt be admitted into the Stove occaſionally at all ſeaſons, for the benefit of the plants in general, by ſliding ſome of the front or top glaſſes open in ſunny days, more or leſs, according to the ſeaſon and temperature of the outward air, &c. obſerving, however, that in winter and early ſpring, air muſt be admitted but ſparingly and cautiouſly, only at favourable opportunities in fine calm ſunny days, opening only ſome of the glaſſes a little way in the heat of the day, for two, three, or four hours, as the weather permits, ſhutting all cloſe timeouſly in the afternoon or ſooner, if the air changes cloudy or very cold; but in ſummer admit air more freely every warm day, and in hot ſun-ſhine weather eſpecially, ſhould ſlide every other light open pretty conſiderably, and in the greateſt heat of ſummer, may open ſome of the glaſſes almoſt at large towards noon: being however careful at all ſeaſons, to proportion the admiſſion of free airy, judiciouſly, both as to time and quantity; not opening too ſoon in the day, before the ſun has ſome power of heat; that in winter or during the cold ſeaſon, may give air in calm ſunny days from about ten or eleven of the forenoon, till two or thereabout, or not ſo long if the weather changes; and in ſummer, from eight, nine, or ten in the morning, till three or four in the afternoon, or an hour or more earlier and later in very hot weather; remarking in general, that in giving air at all times of the year, to ſlide the lights open only a little at firſt in

in the morning, and as the heat increaſes, towards noon admit a larger portion of air, according to the ſeaſon; but when the ſun or heat of the day is on the decline, ſhut the glaſſes cloſer in proportion, having alſo particular attention to ſhut all quite cloſe in due time, at the approach of the weather proving unfavourable, more eſpecially in winter, &c. and always in due time in the afternoon, before the warmth of the encloſed air falls too much below its due ſtandard; generally obſerving the degree of heat on the thermometer.

Watering the plants in Stoves is alſo a material branch of culture to be performed, according as the different ſorts require, which muſt always be applied more ſeldom and ſparing in winter than in ſummer; remarking, the woody or ſhrubby plants, and moſt of the herbaceous tribe that are not ſucculent, require water frequently; the woody kinds require it the moſt frequent, the herbaceous plants in a middling degree, and the ſucculents the leaſt of all; ſo that the woody and common herbaceous plants, in this department, require watering, ſome perhaps two or three times a week in ſummer; and in winter, probably not above once a week; but you will regulate this accordingly, as you obſerve the plants ſtand in need: and always apply the neceſſary waterings with due moderation, juſt to preſerve the earth in the pots moderately moiſt, but never too wet; giving alſo at times occaſional waterings all over the heads of the plants, in ſummer particularly, though but very ſparingly in winter, eſpecially to the *ananas*, *aloes*, and other exotics of ſimilar growth; as the water would lodge long between the leaves of theſe ſorts, at this ſeaſon: nor muſt it be practiſed to the pines when in flower. But as to the ſucculent tribe, they being naturally very replete with moiſture, need but very little water at any ſeaſon, more particularly in winter; except ſuch as ſtand ſo near the hot flues that the ſoil in the pots dry very faſt, when a light watering now and then will be eligible, alſo in hot ſunny weather in ſummer.

But in watering ſuch of the woody plants, &c. as are apt to contract filth or inſects, it is proper to water alſo all over their branches and leaves occaſionally, at almoſt any ſeaſon when the caſe requires it.

For the purpoſe of watering theſe plants, in winter particularly, a ciſtern or tub placed in one corner of the Stove, would be convenient to contain water ſome hours previous to the uſing it, juſt to take off the chilling cold.

Likewiſe, for the convenience of watering the pines and other plants plunged in the bark-bed, or where they are crowded cloſe, a tin pipe made with two or three joints or pieces, to join into one another to lengthen or ſhorten at pleaſure; one of the pieces having a funnel fixed at one end, ſo that by pouring the water into the funnel, may conduct it to any pot in the bark-bed, &c. without wetting the hearts of the plants, which in the pines is to be avoided as much as poſſible in winter, and when they are beginning to ſhew fruit.

The bark-bed will ſupport a good growing heat three or four months, and if in that time the heat is much decreaſed, the pots being taken up, and the bark then forked over to the bottom, breaking all lumps, and mixing the parts well together, immediately replunging the pots, the bed will renew its fermentation, and continue in a proper temperature of heat ſix weeks, or two months longer, or more. Then about March or April, its ſtrength being conſiderably exhauſted, and probably have become earthy towards the top and ſides, then prepare to revive its declining heat by the addition of about one third at leaſt, of freſh tan, previouſly removing the pots, then clearing out all the moſt earthy or crumbly old tan at top, and outſides of the bed; then in its ſtead introduce as much new, as will fill up the pit again, and then fork up the whole, new and old together, plunging the pots again as before; and thus the new bark will promote a freſh fermentation, and renew the heat ſo effectually, as to continue it in good order till autumn; at which time, about September or October, as the bark will be in a manner quite exhauſted, both in ſubſtance and its fermenting property, it ſhould be almoſt entirely renewed with a freſh quantity of new tan; but previous to this augmentation, obſerving if the old tan is not entirely waſted to a ſmall earthy ſubſtance, it may be ſkreened, to ſeparate the ſmall exhauſted materials from the larger unexhauſted bark, clearing out all the ſmall ſtuff that paſſes through the ſkreen, the larger remaining in the pit; then add to this, as much freſh bark as will fill up the pit to the top, forking up the whole, new and old together; though if the whole of

the old tan is become very ſmall and earthy, it ſhould be cleared entirely out, and fill the pit wholly of new bark.

But for more particulars reſpecting theſe bark hot-beds, ſee BARK BEDS.

And as to fire-heat for the Stove, this is required only in winter and ſpring, as before obſerved, to expel the cold and damps, and ſupport the heat of the internal air in a due temperature, as the bark-bed heat alone is not ſufficient in winter; generally beginning to make the fires moderately in the end of October, or beginning of November, when cold or dark foggy weather commences, making gentle fires every night; and as the cold increaſes towards Chriſtmas, encreaſe the ſtrength of the fires in moderation; and in very ſevere, or cold damp foggy weather, continue the fires alſo occaſionally on days, being always cautious never to make them too violent, but ſo as to produce nearly a uniform heat in the internal air, as marked on the thermometer; and thus continue the aid of fire-heat till about April or May, according to the temperature of the weather.

The firing for the Stoves, may be either coal, wood, peat, or turf; but where coal can be eaſily obtained at a moderate expence, I ſhould prefer it for general uſe, as being the moſt ſteady, regular, and durable fuel, requiring leſs attendance than any other; but in default of this, wood, peat, or turf is uſed in many places.

In winter, when the froſt happens to prove very ſevere, it is adviſeable to cover the glaſſes of the Stove every night, at top particularly, to protect the plants; either with ſhutters, canvas, or tarpaulin rollers, or large garden-mats, &c. as formerly mentioned, which covering may alſo be uſed in the day-time occaſionally, if the froſt continues extremely rigorous and no ſun appears; but by no means continue the day-covering to darken the plants longer than it ſhall appear abſolutely neceſſary.

And in the heat of ſummer in very hot ſunny days, it may ſometimes be proper to afford the plants a moderate ſhade of mats, over the top glaſſes for an hour or two, during the violent heat, leſt the ſun ſhining vehemently through the glaſſes ſhould ſcorch the leaves or burn them in holes, and prove detrimental to ſmall tender plants.

Shifting the plants into larger pots, and freſh earth occaſionally, muſt alſo be duly attended to.

Accordingly therefore, as the different plants in the Stove encreaſe in growth, and require larger pots, they ſhould be ſhifted into others a ſize larger; which may be requiſite to ſome plants annually, ſuch as the pine-apples and other free-growing exotics; others once in two years, and ſome not ſo often; ſuch as ſome of the ſmaller ſlow-growing ſucculents, &c. though moſt ſorts of plants in this department will either require ſhifting, or freſh earthing more or leſs every year or two; either in the ſame or larger pots, as their growth may require.

The general ſeaſon for performing theſe works of ſhifting or freſh-earthing, is either in the ſpring about April or May, or early part of autumn, as Auguſt or the beginning of September will be time enough for the plants to ſtrike freſh root in the newly added earth before winter; though if any particular plant ſtand in great need of ſhifting, or is in a bad ſtate of growth, the ſhifting may be performed almoſt at any ſeaſon of the year, chuſing however principally the ſpring or autumn as abovementioned for any general ſhifting.

In performing the ſhifting, generally preſerve the ball of earth entire about the roots, unleſs the roots are ſuppoſed to be in a decayed ſtate, when all the old earth may be cleared away, and the roots trimmed as occaſion require; but thoſe removed with the entire ball, ſhould only have any very mouldy and matted roots round the ſides and bottom of the ball trimmed off, together with a little of the old earth, if it can be done without diſturbing the ball; then having the new pots and freſh compoſt ready, placing pieces of tyle or oyſter-ſhell over the holes in the pots, and ſome freſh earth at bottom, ſet in the plant and fill up round the ball or roots with more new mould almoſt to the top of the pot, giving directly a moderate watering to ſettle the earth cloſe; and thus proceed plant and plant till finiſhed, returning each to its proper place again; plunging all the pines in the bark-bed, and alſo as many of the other plants as room will admit, which will forward their ſtriking or rooting more quickly in the new earth: after which the leſs tender kinds may be removed to the ſhelves, &c. in any part of the Stove.

Such plants however, as do not require ſhifting annually, may be freſh earthed at top, &c. in ſpring; previouſly removing ſome of the old earth from the top, and a little way

way down round the ſides of the pot, then repleniſhing with an equal portion of freſh mould, will prove very beneficial culture, finiſhing each with a very moderate watering to ſettle the earth.

It is of importance in the Stove culture to keep all the plants clear from decayed leaves, by removing all ſuch as ſoon as they appear, as it both tends to preſerve the beauty and health of the plants.

Likewiſe, it is of conſequence to keep all plants confined in Stoves clean from duſt and filth, which moſt ſorts are apt to contract by ſuch confinement, often to their great prejudice if not timely cleaned; this may ſometimes be effected in ſome ſorts, by now and then watering the plants all over their heads, which will waſh off any looſe duſt, and give the plants a lively healthful appearance; though, where any is very foul, is adviſeable to waſh the leaves thereof, leaf and leaf, with a ſponge and warm water, eſpecially the larger or broad-leaved ſorts that admit of it, alſo the ſtems and branches whereſoever any filth is contracted; but as to the pines in particular, and the *aloe* kinds, and others of the like growth, ſhould not be watered all over in winter, becauſe in that ſeaſon the water is apt to lodge between their leaves a long time, ſo ſhould only waſh their leaves when foul with a wet ſponge tied on the end of a ſmall ſtick, for cleanlineſs contributes exceedingly to the proſperity of the plants; duſt or any filth being ſuffered to encreaſe conſiderably, is apt to clog and obſtruct the fine neceſſary organs of perſpiration, as well as the abſorbent veſſels deſtined to imbibe the humidity of the air; thereby cauſe a ſtagnation of the ſap, and the plants aſſume a ſickly ſtate, and often become the prey of inſects: it is therefore effectually neceſſary to keep all theſe plants as clean as poſſible, as it certainly conduces very conſiderably to their health and beauty.

Inſects often infeſt the plants in Stoves, and ſometimes prove very deſtructive to ſome ſorts, particularly the pine-apple; appearing firſt like mildew, and ſoon after aſſume the appearance of lice. The cauſes of them are variouſly aſſigned; ſome impute it to uncleanlineſs and bad ſtate of health, others to the dry air of the Stove, unavoidably occaſioned by the fire-heat, and others to the bad management of the plants; though it is certain we ſhall often alſo ſee plants that are ſeemingly healthful and well managed, ſuddenly attacked with inſects; and when this happens, the plants ſoon aſſume a ſickly appearance. As however this diſaſter of inſects is aſcribed to ſeveral cauſes, ſo are ſeveral methods propoſed for the abolition of them; ſome waſh them with the infuſion of tobacco, &c. i. e. water impregnated with tobacco ſtalks, tobacco duſt, and ſoot, &c. and with this waſh the leaves, ſtalks, and branches; and ſometimes alſo, ſtrew tobacco duſt over the leaves and other parts: others try the effect of fumigation of tobacco, by means of a pair of bellows, furniſhed with a large tin or braſs tube to ſcrew on the noſſel of the bellows at pleaſure, the extreme end terminating in a long pipe, and the tube being filled with tobacco ſet on fire, then by blowing the bellows it produces a ſtrong ſtream of ſmoke from the pipe, which being directed to the parts of the plants infeſted with the vermin, it generally extirpates them pretty effectually, without injuring the plants: various remedies are occaſionally advertiſed in the newſpapers for ſale, both of a powder and liquid kind, to deſtroy theſe Stove inſects; alſo receipts to be ſold for preparing ſuch a compoſition, pretending to be of infallible efficacy.

However, previous to the application of the above remedies to deſtroy the inſects, it is alſo of importance to keep the plants always clean from filth; the bark-bed always of a lively growing warmth, to continue the plants in a free growth, and keep the earth in the pots of a middling degree of moiſtneſs by due moderate waterings, ſprinkling the tops alſo now and then as before obſerved; thoſe however of the pines only in ſummer, for the reaſons before given; applying alſo if needful, any of the other remedies that may be thought the moſt efficacious. Likewiſe, if after all, any particular plant remains ſeverely attacked, and rendered of a very ſickly, weak ſtate by the vermin, it is adviſeable to ſhift it into a new pot and ſome freſh earth, and plunge it into the warmeſt part of the bark-bed, or other good hot-bed under glaſſes, ſtill uſing alſo the other means; and thus the plant will likely aſſume a free growth, and recover its proper health and vigour.

Thus far is principally the general management of a Stove, and culture of the plants at large; and as to the method of propagating the various ſorts, and of any peculiar culture and other occurrences of particular ſpecies, &c. we refer to their reſpective genera for explanations on thoſe heads.

*A liſt of hardy plants, &c. for forcing in Stoves, and general culture.*

As we have already obſerved, that beſides the tender exotics which require the conſtant aid of the Stove, many hardy plants, both herbaceous, ſhrub, and tree kinds, may be occaſionally introduced into the Stove, in order for forcing to early perfection when required.

For inſtance, various hardy herbaceous flower-plants may be forwarded into bloom in the Stove, long before their natural ſeaſon in the open ground; ſuch as early dwarf tulips, hyacinths, polyanthus;—narciſſus, jonquils, and many other narciſſus kinds; anemones, ranunculus, and almoſt any other of the more curious ſorts of bulbous and tuberous flower-plants that may be required early in bloom; previouſly planting the roots in pots in autumn, and place them in a garden frame, &c. to be ſheltered only from froſt till the time arrives for placing them in the Stove, which may be almoſt any time in winter, though if not till towards Chriſtmas or after, we may expect a ſtronger and finer bloom; placing them upon ſhelves towards the glaſſes: or if required to have ſome of them flower as early as poſſible, may plunge the pots into the bark-bed; ſupplying all the ſorts duly with water, eſpecially after they begin to ſhoot; and they will here grow freely without trouble, and produce their flowers both early, and in very good perfection.

Likewiſe pots of pinks, carnations, ſweet-williams, wall-flowers, ſtock-gilliflowers, &c. being placed in the Stove in January, February, or any of the early ſpring months, may be forwarded conſiderably in flowering; alſo many other fibrous-rooted perennials, that may be required early in flower. Likewiſe in the Stove may be raiſed many of the curious annual flowers early from ſeed, and forwarded to an early bloom.

Of eſculent herbaceous plants, may raiſe early kidney beans and cucumbers in great perfection in the Stove; the ſeed, &c. being planted in pots or boxes of rich dry earth any time in winter or early ſpring, placing thoſe of the kidney-beans any where in the houſe, and the cucumbers near the top glaſſes upon ſhelves, juſt over the back walk and flues; may alſo raiſe ſmall ſallading any time in winter, ſown in boxes or large pots, &c. likewiſe ſtrawberries, the plants being trained in the open ground in the garden to a bearing ſtate, either the Alpine or ſcarlet ſort, (ſee FRAGARIA) and being then potted with balls of earth about their roots early in autumn, or even in winter whilſt the weather continues open, and placed in the Stove near the glaſſes any time from January till March, either all at once, or at different times for ſucceſſion, they will produce plenty of fine ſtrawberries. I have alſo forced excellent early aſparagus in the Stove, when there has happened to be a vacancy in the bark-bed to admit of plunging the plants in the tan, as directed in forcing them by dung hot-beds, under the article ASPARAGUS.

As to flowering ſhrubs, if an early bloom is required, they may be forwarded conſiderably in the Stove; ſuch as roſes, honeyſuckles, jaſmines, and various other principal ſorts that have merit in the beauty or fragrancy of their flowers; the plants being previouſly potted, may be placed in the Stove in winter, or any time from January till February or March, &c. either in a common pine-apple Stove, or a forcing Stove, they will flower freely a long time before their natural ſeaſon.

And as to the fruit-tree kinds, ſeveral ſorts may be fruited very early in the forcing Stove particularly, eſpecially moſt of the ſtone fruits, and ſome of the berry kinds; ſuch as cherries, peaches, nectarines, apricots, plums, grapes, and figs; alſo gooſeberries, currants, raſpberries, &c. all of which being previouſly trained in the open ground to a bearing ſtate, then planted in the Stove; or ſome in pots to move to the Stove occaſionally, beginning to force them any time in January, or early in February; ſome being planted finally in the ground or border of earth formed within the Forcing-Stove; others in pots, particularly ſome of the dwarf cherries, and ſmaller fruit ſhrubs; but the peaches, nectarines, apricots, plums, vines, and figs, ſhould generally be planted againſt a trellis erected near the back and front, to be

be trained as wall trees; alſo ſome of the early May and duke cherries; tho' cherries generally ſucceed very well in ſtandards, both full and half ſtandards, and dwarfs; pruning them generally to moderate heads, that they may not become high or ſpreading, to interfere with each other, or ſhade the other trees too much. Vines alſo in particular, may likewiſe be planted in the open ground againſt the outſide of the front of the Stove, and their ſtems trained in through holes made in the wall or timber framing; and the branches within trained up thinly againſt the ſlope and end ſaſhes, &c. to ſlight trellis work fixed to the bearers, ſo as the ſaſhes have full liberty to ſlide; obſerving ſuch vines as are thus trained in from the outſide of the Stove, ſhould in winter when ſevere froſts prevail, have that part of their ſtems without, defended by a cloſe wrapping of hay-bands; alſo the ground over their roots, eſpecially towards ſpring, when the vines begin to ſhoot withinſide of the Stove.

Remarking, as to the time to begin forcing by fire-heat the above hardy plants and fruit-trees, that, if in a forcing Stove for the purpoſe, January or beginning of February is the proper ſeaſon; then ſhut all the glaſſes cloſe, except giving air occaſionally as hereafter hinted; making the fires moderate at firſt, encreaſing their ſtrength gradually, though always in a moderate degree, never above the temperature of the pine-apple ſtandard, continuing the fires every night and morning in the above moderate manner; alſo occaſionally in the day time, in ſevere froſts or cold damp weather. If, however, there is only a common pine-apple Stove for general uſe, you ſhould generally have all your plants intended for forcing planted in pots, &c. in order that they may be moved into the Stove only at the proper ſeaſon; or, to have a regular ſucceſſion, may introduce them at two or three different times, at a fortnight or three or four weeks interval, having plants, &c. for this purpoſe ready potted, and in winter placed under occaſional ſhelter from froſt, till placed in the Stove.—All the plants thus forced in the Stove muſt be allowed the benefit of freſh air in fine days, and occaſional waterings; as to freſh air, if in a common pine-apple Stove they can only enjoy the advantage of air in common with the other plants in that department, as directed in the culture of Stove plants: but if they are in a forcing Stove by themſelves, freſh air may ſometimes be admitted more freely, eſpecially after the plants have begun to ſhoot; chuſing, however, only fine mild ſunny days for this, by ſliding open the lights a little in the heat of the day; encreaſing the portion of air as the warm ſeaſon advances, ſhutting all cloſe towards evening: and as to water, all the plants, both herbaceous kinds, ſhrubs, and trees, will require occaſional moderate waterings; thoſe in pots will require it more frequent than ſuch as are planted fully in the ground: chuſing generally warm ſunny weather for this work, eſpecially in winter and early ſpring; and give it always in due moderation.

As ſoon as theſe forced hardy plants are paſt perfection, either as to flowering or fruiting, &c. thoſe of them you intend preſerving for future uſe, and that are in pots, ſhould be moved into the open air, to recover themſelves, as ſome of them may ſerve for the open ground, and ſome alſo to force again after having a ſummer's growth in the full air, eſpecially the ſhrub and tree kinds; and as to ſuch as are planted in the full ground in forcing Stoves, ſhould, as ſoon as the flowers and fruit are paſt, be fully expoſed to the open air, by removing all the glaſſes, that they may receive the full advantage of the air, ſhowers, dews, &c. all ſummer, and until nearly the arrival of next forcing ſeaſon, that they may regain proper ſtrength and vigour to yield their produce in due perfection the following year; obſerving towards winter, or at the approach of ſharp weather, to put on the glaſſes again, in order to give occaſional ſhelter till the time to begin forcing, and then the Stove muſt be ſhut up cloſe, and managed as before.

According as any of the fruit-trees fail, or become bad bearers, let them be removed in due time, and their place ſupplied with new ones from the nurſery.

STROBILUS, a ſpecies of ſeed-veſſel commonly called *Cone*.

The *Strobilus* or Cone *(Conus)* is the fruit or ſeed-veſſel of the coniferous or cone-bearing trees, ſuch as pine, fir, cypreſs, juniper, &c. being of a conical figure, formed of a conic *amentum*, compoſed of ſcaly imbricated calices, becoming ſo many hard woody ſcales, laid over on one another like tiles, cloſely involving the ſeeds. See CONIFERÆ and CONUS.

This

This ſpecies of ſeed-veſſel being generally of a conical form is commonly called a Cone, (*Conus.*)

STYLUS, the Style of the flower.

The Style is that long ſlender part of the *piſtillum* placed on the top of the germen, in the center of the flower, elevating the ſtigma or ſummit of the *piſtillum*, or female organ; and is correſponding to the vagina in animals, as being the tube through which the effluvia of the farina or fertilizing male duſt of the antheræ emitted on the ſtigma, paſs to the germen or ſeed-bud, for the impregnation of the embryo ſeeds. See PISTILLUM, GERMEN, and STIGMA.

Every female and hermaphrodite flower is furniſhed with a *piſtillum*, and conſiſt of three parts, viz. the germen, Style, and ſtigma; the germen ſupports the Style, and the Style the ſtigma on its ſummit. Thus the Style connects the germen and ſtigma; and in plants apparently without, or with but a very ſhort Style, the ſtigma is placed on the germen; as in *papaver*. The number of Styles vary in the plants of different genera, the greater number having only one Style, others two, three, to five, ten, or many Styles, which in each flower is generally equal in number to that of the germen or ſeed-bud, each germen being furniſhed with its own particular Style; ſo that flowers having but one germen have generally but one Style; and thoſe with two, three or many germens, have the like number of Styles. There are, however, ſome exceptions, as there are plants which have more than one Style for a ſingle germen or ſeed-bud, as in the umbelliferous tribe; others on the contrary have a ſingle Style common to many ſeed-buds, as in the verticillate tribe of lip flowers. And in another tribe of plants the Style is ſingle at its origin, but ſoon divides or branches out into as many ramifications as there are diviſions or cells in the cavity of the ſeed-bud, ſuch as in the geraniums and mallow tribe, which have their Styles divided above into five branches, correſponding to the five diviſions of the ſeed-bud or capſule.

From the number of Styles, and in their abſence that of the *ſtigmata* is founded the orders or ſecondary diviſions of the claſſes in the ſexual method. See CLASSES and ORDO.

The Style in moſt plants is erected like a column in the centre of the flower; in ſome, however, the Style is nodding or reclined, or in others is revolute or bent backwards; and ſometimes as in *nigella Arvenſis*, the five Styles being longer than the ſtamina, are firſt erect; afterwards when the flower is fully expanded, they are bent back, that the ſtigmas may touch the anthera of the ſtamina or male organ; and having thereby received the male duſt, they are again elevated, and ever after remain erect. For the moſt part the Style is always ſurrounded by the ſtamina, ſo that ſome of the *pollen* or male duſt of the antheræ is blown by the wind on the *ſtigma*.

As to proportion and dimenſion, the Style is either of equal length with the *ſtamina* as in moſt flowers; much longer, as in ſome others; and in ſome very ſhort, or even wanting, as in *papaver*, &c. in which the *ſtigma* ſits cloſe to the germen; and in ſubſtance the Style in ſome plants is thicker than the *ſtamina*; in others of equal thickneſs, and in ſome ſlenderer.

As to figure, the Style is either cylindrical and hollow like a tube, as in moſt plants; angular, as in *cana*; awl-ſhaped or tapering as in *geranium*; capillary or ſlender like a hair; or club-ſhaped, being thicker above than below, as in *leucoium*, the greater ſnow-drop, &c.

In point of ſituation, the Style is ſituated either on the top of the germen, as in moſt flowers; above and below the germen, as in *cappavis* and *euphorbia*; or on one ſide of the germen, as in roſe, raſberry, and other plants of the *icoſandria polygynia*; or on the baſe of the germen as in *alchemilla* or ladies-mantle, &c.

In reſpect to duration, the Style is either deciduous, falling off with the other parts of the flower, after the impregnation, as in moſt plants; or ſometimes permanent or abiding, as in the cruciform flowers of the *tetradynamia*.

STYRAX.

Storax, or Sweet Gum-tree.

It is a deciduous aromatic tree of the Eaſt, retained in our gardens to diverſify the greenhouſe and ſhrubbery collections; is famous for its medical gum called Storax, being a fragrant reſinous fluid, which the tree imparts by inciſion in the trunk; the very wood alſo imparts a ſweet odour.

Claſs

Claſs and order *Dodecandria Monogynia.*

*Characters.*] CALIX is ſhort, cylindric, monophyllous, and quinquedented.—COROLLA is monopetalous, infundibuliforme, with a ſhort cylindric tube, and ſpreading limb divided into five obtuſe ſegments.—STAMINA, about twelve or more awl-ſhaped filaments, diſpoſed circularly, having oblong erect antheræ.—PISTILLUM, a roundiſh germen below the corolla, ſingle ſtyle, with a truncated ſtigma.—PERICARPIUM, a roundiſh, unilocular, drupaceous fruit, containing two roundiſh nuts, convex on one ſide.

There is but one ſpecies, which in this country generally requires the culture of hardy green-houſe plants, during its minor ſtate; but when hardened by degrees to a more mature growth, it may be turned out into the full ground in a warm ſituation, finally to remain.

The ſpecies is,

STYRAX *officinale.*

*Common or officinal Styrax.*] Riſes with a woody ſtem, branching on every ſide, twelve or fifteen feet high, or more, covered with a ſmooth greyiſh bark, oval, moderate-ſized, alternate leaves, hoary underneath; and bunches of white odoriferous flowers at the ſides of the branches in June; ſucceeded ſometimes by fruit, but rarely ripens in England.

This tree is a native of Syria, and moſt parts of the Eaſt; where it is highly valued for its fragrant medical gum; which it exſudes from the trunk and branches.

It is, although an exotic of hot countries, moderately hardy, as in this country it only requires ſhelter of a frame or green houſe from ſevere froſt while young, for three or four winters; afterwards may be planted in the full ground againſt a ſouth wall, and other ſheltered ſituations; training ſome againſt the wall, others take their natural growth, and allow occaſional ſhelter of mats in very ſevere weather.

It is propogated commonly by ſeeds, obtained from abroad by the ſeedſmen; ſowing them in pots of light earth an inch deep, obſerving as they are of a hard ſtony nature, they rarely come up the firſt year; ſo it is proper to plunge the pots under a frame during cold weather, and in the ſhade in ſummer, and in the ſecond ſpring; then as the ſeed will be ready to germinate, if plunged in a hot-bed, it will forward them exceedingly, being careful to give water, and to harden the ſeedlings gradually to the full air in ſummer, in a ſhady place during the hot weather, and often watered; and in winter place the pots under a garden-frame, &c. to have ſhelter from froſt; then in ſpring following pot them off ſeparately, and manage them as hardy green-houſe plants for three or four years, when ſome of them may be turned out unto the full ground in a ſheltered ſituation, as already hinted, and ſome may be retained in pots for the green-houſe collection.

SUCCULENTÆ, (*Succus*, Juice) Succulent plants.

Succulent Plants are ſuch as have thick fleſhy leaves, &c. abounding with juice, being principally of the herbaceous tribe; and ſome become of a ligneous nature in the ſtem, though Succulent in leaf; and of the Succulent kind there are perennials, biennials, and annuals; but principally perennial and evergreen.

Of the Succulent tribe many are tender exotics, inhabitants of the hot parts of the world; and ſome are of hardy growth; are moſtly inhabitants of dry barren ſoils, and rocky places; many of which being of ſingular growth, are retained in our garden collections as plants of variety and curioſity; conſiſting of many different genera, each compriſing more or leſs varieties, ſome for the green-houſe and ſtove, and ſome for the open ground. The following is a liſt of the principal genera, and their varieties, collected into one point of view, referring to their reſpective articles for particulars.

AGAVE, Great Amenum *Aloe.* (*All the ſpecies.*)

ALETRIS, Guinea *Aloe.* (*All the ſpecies.*)

ALOE, African *Aloe.* (*All the ſpecies.*)

ANTHERICUM, Spider-wort. —— Aloe-leaved. — Mock Aſphodel.——*Anthericum*, Shrubby, Onion-leaved.

CACALIA, Foreign Colts-foot.—Ficoides African Cacalia.—Anteuphorbium Æthiopian *Cacalia.*—Kleinia or Indian *Cacalia.*—Papillary Æthiopian *Cacalia.* — (*All of ſomewhat ſhrubby growth.*)

CACTUS, Melon-thiſtle, including alſo the *Cereus* or Torch-thiſtle, and the Opuntia, or Indian Fig. (*All the ſpecies.*)

COTYLEDON, Navel-wort. (*All the ſpecies.*)

CRASSULA, Leſſer Orpine. (*Moſt of the ſpecies.*)

EUPHOR-

EUPHORBIA, Burning thorny plant. — (*Moſt of the ſorts.*)

MESEMBRYANTHEMUM, Fig Marigold. (*All the numerous ſorts.*)

PORTULACA, Purſlane. (*All the ſorts.*)

SAXIFRAGA, Saxifrage. —— Cotyledon Saxifrage, &c.

SEDUM, Leſſer Horſe-Leek, Orpine, and Stone-crop. (*Moſt of the ſorts.*)

SEMPERVIVUM, Live-ever, or Common Houſe-leek. (*All the ſorts.*)

TETRAGONIA. (*Both the ſpecies.*)

YUCCA, Adam's Needle. (*All the ſorts.*)

ZYGOPHYLLUM, Bean-caper. (*Moſt of the ſorts.*)

As many of theſe Succulents are eſteemed ſingular curioſities in the vegetable creation, they are cultivated as ſuch in moſt of our eminent gardens; a general deſcription of the different ſorts, their propagation and culture, may be ſeen in the proper places, under the heads of their reſpective genera.

They are moſtly of a very carnoſe or fleſhy nature, both in ſtem, leaves, &c. abounding with humidity, and moſtly evergreen; and many of them aſſume great ſingularity in their general port or habit; and as to magnitude, ſome when they flower obtain thirty or forty feet ſtature, as the *agave Americana*; others, ſuch as the ſtone-crop, &c. not above three or four inches. See each under its proper genus.

Moſt of the ſorts being originally inhabitants of dry ſoils, or ſaxtile or rocky ſituations, walls, tops of old buildings, and ruins, &c. and being naturally all very replete with moiſture, ſhould therefore in their culture be moſtly planted in light dry, lean earth, or dry rubbiſhy compoſt (ſee COMPOSTS); otherwiſe, on account of their great humidity, are very apt to rot off in winter, more particularly the very Succulent and tender kinds of the green-houſe and ſtove (ſee GREEN-HOUSE and STOVE PLANTS); and which ſorts in particular are always to be kept in pots, in order to be placed among the plants of thoſe two conſervatory departments, as their nature or temperament require, and managed accordingly, as hinted under the *Culture* of *Green-houſe* and *Stove-Plants* aforeſaid: always kept from too copious moiſture; for as they naturally abound in juice, they require very little water at any ſeaſon; but in winter eſpecially ſhould have it but very ſeldom and ſparing; and ſome of the moſt Succulent hardly any water during all that ſeaſon.

And as to the hardy kinds, ſuch as the common houſe-leek, or pine, ſtone-crop, &c. (ſee their proper genera) will grow in the open air, on rock-work; dry rubbiſhy borders, tops of walls and buildings; and are proper plants to introduce in artificial ruins and rocks, &c.—May alſo be planted in pots to move to any place occaſionally. With reſpect, however, to the general deſcription, uſes, propagation, and culture of this tribe of plants, we refer to their reſpective genera, where every thing is fully exhibited; but the principal curious ſorts being only here brought under one head, ſerves as a hint of the nature of theſe kind of plants, and to aſſiſt the memory, ſo as more readily to furniſh a collection of the different ſorts.

SUCCUS, Sap, or the Juices of Plants.

The main vegetable juices or fluids are drawn by the root from the body it adheres to, whether it be earth, water, or other ſubſtance; thence aſcends to the ſtem, branches leaves, flowers, and the minuteſt part of the fructification, &c. But whether the ſame Sap, ſo diffuſed to the extremities of the plant, ever returns, and that there is a circulation of Sap in plants analogous to that of the blood in animals, is a queſtion, which will probably never receive a ſatisfactory anſwer.

Though many of the eminent naturaliſts contend for the circulation, and that the ſame juice deſcends again to the root; yet by accurate experiments it appears, that the Sap aſcends not by the bark, but by the capillaries or fibres of the wood; and the curious obſervation of many renders it highly probable that the fluid which aſcends by the ſaid capillary veſſels of the wood, deſcends to the root by the larger fibres of the inner bark that are moſt contiguous to the woody body. In ſupport of this, the ſame experiments of ligature and inciſion which evince a circulation of the blood in animals, ſucceed in the like manner in vegetables, particularly in ſuch as abound with a milky Sap; ſince if the ligature or bandage is faſtened tight round them, the part above is found to ſwell very conſiderably, and that below it only a little, whence it appears there is a juice deſcending from the branches: and as to the experiment of inciſion, it has likewiſe been obſerved, that upon a tranſverſe inciſion being made into the trunk of a tree, the juice which is ex-

expended or flows from the wound, proceeds in greater quantities from the upper lip of the gash, where the ſwelling likewiſe is much larger than below; ſo that from the reſult of ſuch experiments it is rendered ſomewhat more than probable, that the ſap returns from the extremity of the branches to the root; thence into the earth again. But ſome contend, that inſtead of the ſame juices going and returning, there are two ſeveral juices; the one terreſtrial, as being imbibed from the ſoil, digeſted in the root, and from thence tranſmitted to the extremity of the plant; the other is ſuppoſed to be aerial, and received from the moiſture of the air entering in at the extremity of the branches, and ſurfaces of the leaves. So according to this concluſion, the aſcending and deſcending juices are not the ſame; and indeed with reſpect to the aerial ſap, experiments have determined that the plant derives part of its nouriſhment by the extreme branches, and the leaves in general, and that the leaves contribute greatly both to the abundance and motion of the ſap; for it is obſervable of new-planted trees in particular, having many of their branches lopped, they will not proſper near ſo well as thoſe trees left entire; and if a tree when high in ſap is diveſted of its leaves, it will be found to retard the growth, both of its ſhooting, and that of the flowers and fruit.

However, the firſt and principal ſap of a plant is furniſhed by the earth entering the roots in form of a fine and ſubtle water, which, the nearer it is to the root, the more it retains of its proper nature; and the farther from the root the more action it has ſuſtained, and the nearer it approaches to the nature of the vegetable.

But what courſe the ſap takes after it is imbibed by the roots, is not very clear; the veſſels that take it up to convey it to the plant, are too fine to be traced, and hence it remains doubtful, whether it is by the bark, or the woody part, or the pith that the plant is fed.

In this the naturaliſts differ in opinion. Some contend for the bark, others for the wood, though in the former caſe they obſerve, that the juice raiſed from the earth by the capillary tubes or pores of the wood is here ſuppoſed to deſcend by the larger fibres placed in the inmoſt part of the bark immediately over the wood; in which deſcent the ſap being now ſufficiently prepared adds ſome of its ſubſtance to the contiguous wood, and thereby gradually encreaſes its bulk, ſo that the bark is thus alſo ſuppoſed to ſerve divers purpoſes; for it not only tranſmits the nutritious juices to the plant, but likewiſe contains certain fat oily juices to defend the fleſhy external parts from the injuries of the weather.

In ſome caſes, even the whole plant is no more than bark; the pulp or woody part having been eaten or rotted out, except juſt the outſide ſhell, as often occur in willow, elm, &c. yet continue growing, and live a long time in that ſtate.

On the other hand, thoſe who contend that the wood conveys the principal nouriſhment, obſerve, that the whole woody body conſiſts entirely of ſlender longitudinal capillary tubes or fibres, running parallel to each other from the root up the trunk and branches, being proper to receive in a fine vapour or humour, in the aſcent of which the fibres become open, and their ſubſtance encreaſed. And thus the trunks of trees are ſaid to encreaſe in their circumference.

The motion of the nutritious juices of vegetables is found to be produced much like that of the blood in animals, by the action of the air, &c. for it is diſcovered that vegetables conſiſt of two orders of veſſels; 1. ſuch as receive and convey the alimental juices, anſwering to the arteries, lacteals, veins, &c. of animals; 2. the *tracheæ*, or air-veſſels, being long fine pipes or tubes poſſeſſing principally the wood or ligneous body, and ſerve to receive and tranſmit the air, neceſſary for preparing and giving motion to the humours or juices.

As to the nature of the vegetable fluids, it appears, that plants contain many different juices, ſuch as thoſe of the root, ſtem, bark, &c. thoſe of the leaves, the juices of the flowers, or genitals, and thoſe of the fruit, the preparative of the laſt, of which may be ſaid to be nature's final work.

However, the principal vegetable juices are generally reduced to two; the lymph or ſap; and the proper juice or blood of plants.

1. The lymph or ſap is a ſimple fluid, being without colour or ſmell, and little different from water; and mounts from the root to the ſtem, and remote parts of the plant, as before obſerved, in its proper veſſels, which are woody longitudinal hollow fibres, almoſt inconceivably fine, and always replete with ſap; which, however, in ſpring, is found in greateſt abundance, and then the bark is

eaſily detached from the wood. On the contrary, when the ſap-ſeaſon is paſt, the bark is found cloſely applied, and, as it were, glued to the wood; or when a tree is in high ſap, and ſtripped of the leaves, the bark, in a few days, will adhere as cloſely to the wood as in winter.

2. The other principal fluid, denominated the proper juice or blood of plants, and analagous to the blood in animals, contained in proper veſſels, called likewiſe from their uſe vegetable blood, are ſtraight longitudinal fibres, larger than the lymphatic or ſap veſſels, and leſs numerous, which are filled with the proper juice, which is generally compound or coloured, and eaſily diſtinguiſhed by its colour, ſmell, and ſubſtance, from the lymph or ſap, it being either green, as in ſome plants, white as in ſpurge, fig-tree, and dog's-bane; yellow, as in celandine, red as in dragon's blood, mucilaginous or gummy, as in the jujube and mallow tribe, or reſinous, as in the coniferous plants. So it is from the variety in colour and ſubſtance that the fluid in queſtion is called the proper juice; each ſpecies of plant being ſuppoſed to contain a fluid peculiar to itſelf; and in this proper juice reſide the ſmell, taſte, and virtue of the plants.

SUCKERS.

Suckers are young offspring plants, ariſing immediately from the roots of older vegetables; and being tranſplanted, readily grow and become proper plants, in all reſpects like the mother plant that produced them, being therefore very eligible for the work of propagation.

So that Suckers may be conſidered as a ſort of vegetable ſpawn or progeny, emitted from the roots of certain trees, ſhrubs, and other plants, to propagate their reſpective ſpecies and varieties: and a very conſiderable ſhare of the vegetable creation multiply exceedingly by this means; for numerous ſorts continue ſending up great plenty of Suckers every ſummer, each Sucker furniſhed with roots or fibres, and in one ſeaſon form proper plants for tranſplantation; thus proving a very plenteous and expeditious method of propagation both for numerous tree and ſhrub kinds in particular, as well as for many herbaceous vegetables; which ſending up Suckers from the root in ſpring and ſummer, will be fit for tranſplanting the following autumn.

The propagation by Suckers is alſo, in certain caſes, a ſure method to continue any approved or intended ſpecies, or variety, the ſame; remarking, however, of grafted and budded trees, that Suckers partake only of the nature of the ſtock; as for example, ſuch Suckers as ariſe from a codlin ſtock, grafted with any other ſort of apple, will continue invariably a codlin, without partaking any thing of the nature of the graft; the ſame being alſo obſervable of all other grafted trees and ſhrub kinds; obſerving therefore not to miſtake ſo far in propagating by Suckers from the roots of grafted and budded trees, worked on different ſtocks, to ſuppoſe the Suckers will produce the ſame ſort of fruit, &c.

But in trees, &c. that are wholly the ſame ſort root and top, the Suckers thereof will alſo prove the ſame invariably in every mode of growth, as certainly as is obtained by layers, cuttings, grafting, &c.

As to the ſeaſon for taking up or tranſplanting Suckers, it may be performed almoſt any time in open weather from October till March, being careful to dig them up from the mother-plant with as much root or fibres as poſſible, and trim them ready for planting, by ſhortening long ſtraggling fibres, and cutting off any thick knobbed part of the old root that may adhere to the bottom, leaving only the fibres ariſing from the young wood; though it is probable ſome will appear with hardly any fibres; but as the bottom part having been under ground, and contiguous to the root of the main plant, they will naturally be much diſpoſed to ſend forth plenty of fibres for rooting. The ſtems of ſome of the ſhrub and tree kind particularly, will alſo require trimming occaſionally, ſuch as cutting off all lower laterals; and if any have long, ſlender, and weak tops, or ſuch that you intend ſhall aſſume a more dwarfiſh or buſhy growth, may be ſhortened at top in proportion, to from about half a foot, to one or two feet in length, according to their nature or ſtrength, and as the caſe may require: others that are more robuſt and ſtrong, or that you deſign ſhall run up with taller ſtems, may have their tops left entire, or ſhortened but little, as it ſhall ſeem neceſſary for the uſes intended.

Being thus taken up and trimmed, proceed to plant them in rows in the nurſery; the weak Suckers plant ſeparately in cloſe rows; alſo the ſhortened ones by themſelves, and the ſtronger plants likewiſe ſeparately in wider rows; ſo that the rows may be from one

one to two feet aſunder, in proportion to the ſize and ſtrength of the Suckers.

After being thus planted out in nurſery rows, allow them the common nurſery culture of cleaning from weeds in ſummer, and digging the ground between the rows in winter, &c. and in from one to two or three years; they will be arrived to due ſize for final tranſplantation.

Though ſome kinds of trees, &c. produce Suckers ſo ſtrong in one ſeaſon as to be fit for planting at once, where they are finally to remain; ſuch for example, as ſome ſorts of roſes, and numerous other flowering ſhrubs; likewiſe ſome of the ſtrong-ſhooting gooſeberries, currants, raſberries, and the like kinds.

And ſometimes many of the ſhrub kind in particular, having produced a quantity of Suckers from the root, and theſe ſuffered to ſtand and grow up, each to a large plant, the whole from one root forming a conſiderable buſh, as may often be obſerved in gooſeberries, currants, and many other ſhrubs; and in which caſe each ſuch buſh being taken wholly up at the proper ſeaſon before mentioned, may be divided to the bottom into ſo many ſeparate plants; and as each Sucker will be amply furniſhed with plenty of roots, and of due ſize for flowering and fruiting, may plant them, if required, at once, where they are always to ſtand.

But the propagation by Suckers is by ſome objected to for any general ſupply, on a ſuppoſition that the trees, &c. ſo raiſed, are more adapted to run too conſiderably to Suckers, and over-run the ground, than ſuch as are raiſed by any other method: however, it may generally be obſerved of ſuch trees and ſhrubs as are naturally diſpoſed to ſend up many Suckers, that by whatſoever method they are propagated, whether by ſeeds, ſuckers, layers, cuttings, &c. they commonly ſtill continue their natural tendency to multiply by Suckers in the ſame abundance.

However, when it is required to have any ſorts produce as few Suckers as poſſible, not to over-run the ground, or diſfigure the plants, it is proper both at the time of ſeparating the Suckers, or planting them off from the main plant, and at the time of their final removal from the nurſery, to obſerve if at the bottom part they ſhew any tendency to emit Suckers, by the appearance of prominent buds, ſhould rub all ſuch off as cloſe as poſſible, which will prevent the production of Suckers proportionably.

As, however, many ſorts of trees and ſhrubs are ſubject to throw out Suckers, conſiderably more than may be wanted at all times for multiplication; and that if permitted to remain, would over-run the ground, and become unſightly, as well as prejudice the parent plants; they ſhould therefore be always cleared away annually at leaſt: but if not wanted for propagation, it is proper to eradicate them conſtantly as they are produced in ſpring and ſummer.

SUFFRUTICOSUS *Planta.*

Under-ſhrubby Plants.

Suffruticoſe Plants are a ſort of ligneous or ſomewhat woody vegetables, that are between a ſhrubby and an herbaceous nature, exemplified in thyme, ſage, hyſſop, winter-ſavory, and ſuch like plants.

SUN.

The Sun is doubtleſs the firſt mover of all vegetable motion; for as the naturaliſts obſerves, the Sun qualifies the air, which otherwiſe by its great frigidity would ſtop the whole courſe of nature: but by the Sun's diffuſive power of light and heat, it exhilerates not only the race of mankind, &c. but the vegetable creation.

Its genial chearful rays promotes the growth of all vegetables, by its influence upon the ſoils; warming and chearing the pores of the earth, when diluted and ſodden with too much wet, and puts the fibres of plants in motion for ſeeking their food; and its influential power operates on the branches, leaves, and fruit.

Plants, therefore, which in their growth are more or leſs expoſed to the Sun, are, for the moſt part, more proſperous, forwarder, and attain greater perfection than ſuch as grow in any conſiderable ſhade.

Likewiſe moſt fruits in a ſunny expoſure are conſiderably more beautiful, ſooner ripe, and acquire ſuperior quality in flavour, &c. to thoſe growing in ſhady places.

The Sun's attractive power is very conſpicuous in the exhalation or diſpelling of thoſe crude and unwholeſome vapours with which the earth is ſo often infeſted, which would otherwiſe make it noxious, and render the earth a miſerable deſart: but more particularly the Sun warms, and enriches the ſoil, and prepares the juices for being ſucked in by the fibres of plants.

For this reaſon, ground deſigned to be fallow, ſhould always be turned up in rough ridges, to give free acceſs to the influence of the ſun and air. Likewiſe all compoſt heaps ſhould generally be prepared in ſunny ſituations, in the full air, not in bye ſhady corners, or in ſheds, as often practiſed.

SYMPHYTUM, Comfrey.

This genus of plants conſiſts of hardy herbaceous perennials, for variety in gardens and medicinal purpoſes, having long fleſhy roots ſending up annual ſtalks from half a yard to two or three feet high, adorned with oval and ſpear-ſhaped leaves, and terminated by monopetalous bell-ſhaped flowers.

Claſs and Order *Pentandria Monogynia.*

*Characters.*] CALIX is upright, pentagonal, five-parted at the brim, and permanent. —COROLLA is one bell-ſhaped petal, with a very ſhort tube, a tubular ventricoſe limb; divided at the brim into five obtuſe reflexed ſegments, having the chaps or opening armed with five ſubulate rays connected in a cone. —STAMINA, five awl-ſhaped filaments, placed alternately with the rays of the chaps of the corolla, and erect acute antheræ.—PISTILLUM, four germina, ſupporting a filiforme ſtyle, crowned with a ſimple ſtigma.—PERICARPIUM, none; four gibbous, acute pointed ſeeds lodged in the permanent calix.

There are but three ſpecies, one is an inhabitant of England, the other two is of foreign growth, and are all hardy plants.

The ſpecies are

[1] SYMPHYTUM *officinalis.*

*Common officinal Comfrey*] Hath long, thick, fleſhy, deeply-ſtriking roots, black without and white within; crowned with large, oval, ſpear-ſhaped, rough leaves; upright, thick, branchy, rough ſtalks, two or three feet high, garniſhed with decurrent leaves, and terminated at top by bunches of drooping flowers, of different colours in the varieties, appearing in June and July.

*Varieties are*] Common white flowered—purple-flowered — blue-flowered — yellow-flowered — red-flowered: but the white and purple are the moſt common.

It grows wild in England, eſpecially the white-flowered ſort, by ditch ſides, and other humid ſhady ſituations; but is ſometimes kept in gardens for variety and medical uſes, the root being the uſeful part.

[2] SYMPHYTUM *tuberoſum.*

*Tuberoſe-rooted German Comfrey*] Hath a root compoſed of many thick fleſhy tubers, ſending up inclinated rough hairy ſtalks a foot and a half high, long, narrow, acute-pointed, rough, hairy leaves, alternate below, and oppoſite at top; and the ſtalks terminated by bunches of pale yellow flowers, in June and July.—Grows naturally in Germany, France, and Spain.

[3] SYMPHYTUM *Orientale.*

*Oriental Comfrey*] Hath a thick fleſhy root, upright rough ſtalks, half a yard or two feet high; oval rough leaves, on ſhort hairy foot-ſtalks, and the ſtems terminated by drooping bunches of blue flowers, in March and April. It grows by river ſides in the Eaſt, near Conſtantinople.

All theſe three ſpecies are of the herbaceous tribe, and perennial in root, but annual in leaf and ſtalk, which riſe in ſpring, and produce flowers and feed the ſame year; the firſt and ſecond ſort in particular ripen plenty of ſeed; the other not always in perfection in England: and ſoon after the ſeed is ripe, the ſtalks decay.

As to their merit as garden plants, they may be employed in large herbaceous collections, to encreaſe the variety in the pleaſure-ground; and the firſt ſort in particular. SYMPHYTUM *Officinalis* may alſo be introduced in gardens as an officinal plant in medicine: all the three ſorts are very hardy, and will proſper in any common ſoil and expoſure; but delight moſt in ſhady moiſt places; planting thoſe deſigned for variety thinly, in aſſemblage with other hardy perennials, and thoſe intended for medical uſes plant in beds or borders together, in rows, two feet aſunder.

*Method of Propagation, &c.*

Their propogation is affected by ſeed, and by parting the roots.

By Seed.—Sow it in ſpring in a bed or border of common earth, and rake it in: they will ſoon come up plentifully, and in autumn the plants will be fit to tranſplant where wanted, in the manner above obſerved.

By parting the Roots.—This may be effected with expedition, and abundance in autumn, or early ſpring. Almoſt every bit of the root will grow, planting them either in nurſery beds, or at once where they are to remain; and they will ſoon multiply into large plants.

SYRINGA,

SYRINGA, Lilac.

Two noted deciduous flowering ſhrubs compoſe this genus, each comprehending ſeveral elegant varieties, adorned with oval heart-ſhaped and ſpear-ſhaped ſimple leaves, and large bunches of ſmall, monopetalous, funnel-ſhaped, odoriferous flowers, of a very ornamental appearance.

Claſs and order *Diandria Monogynia.*

*Characters.*] CALIX is ſmall, monophyllous, tubulated, four-parted at the brim, and permanent. — COROLLA is monopetalous, funnel-ſhaped, with a long cylindrical tube, divided above into four narrow revolute ſegments.—STAMINA, two very ſhort filaments, with ſmall antheræ.—PISTILLUM, an oblong germen, ſlender, thread-like ſtyle, and a thick bifid ſtigma. — PERICARPIUM, an oblong, compreſſed, acuminated, bivalvous, bilocular capſule, having a ſingle ſeed in each loculi, being oblong, acuminated, and with a membranaceous border.

There are only two ſpecies, which, and their varieties, are fine ornamental furniture for the ſhrubbery compartments. Are ſuppoſed to be natives of Perſia, but have been long in the Engliſh gardens as eminent flowering ſhrubs.

The ſpecies are

SYRINGA *Vulgaris.*

*Common Lilac*] Riſes with an upright ſhrubby ſtem, ſoon dividing into many branches, and grows fifteen or twenty feet high; garniſhed with oval-cordated, or heart-ſhaped leaves, placed oppoſite; and the flowers produced at the ends of the young ſhoots, in large, erect, conical bunches, of different colours in the varieties, appearing in May.

*Varieties are*] White-flowered — blue-flowered—purple-flowered, or Scotch Lilac.

This ſpecies and varieties have been long reſidents of our gardens, as elegant flowering ſhrubs, to decorate the wilderneſs and ſhrubbery clumps; are all ſo very hardy as to grow almoſt any where without trouble, exhibiting a very ornamental appearance, in the great profuſion of their flowers, which alſo imparts a very agreeable odour.

SYRINGA *Perſica.*

*Perſian Lilac, ſometimes erroneouſly called Perſian Jaſmine*] Riſes with a ſlender ſhrubby ſtem, dividing into long, ſlender, flexible, browniſh branches, growing five or ſix feet high, adorned with narrow, ſpear-ſhaped, entire leaves, placed oppoſite; and the young ſhoots, terminated by long paniculated bunches of bluiſh, and other coloured flowers in the varieties; appearing the end of May, and beginning of June.

*Varieties are*] Common purple-flowered, —white-flowered — blue-flowered — laciniated, or cut-leaved Perſian Lilac, having the leaves deeply cut into ſeveral ſegments. All of which varieties of this ſpecies are moſt delightful flowering-ſhrubs, and their flowers have an agreeable fragrance.

Both theſe ſpecies of Lilac, and their varieties, are very hardy ſhrubs, of the deciduous tribe; and although originally inhabitants of Perſia, grow freely in the open ground in any expoſure, and reſiſt the ſevereſt froſts; having been many years in the Engliſh gardens as ornamental flowering ſhrubs; all the ſorts flowering profuſely, and ornamentally, early in ſummer, each panicle of flowers being large and conſpicuous, compoſed of numerous florets, or ſeparate flowers, and continuing near three weeks in beauty, ſucceeded in the firſt ſpecies, and its varieties, by plenty of ſeed; but the ſecond ſort rarely ripen any in England.

As therefore theſe fine ſhrubs are ſo hardy, and eaſy of culture, they highly merit admittance into every pleaſure-ground, large or ſmall, being excellently adapted both to embelliſh the premiſes, and encreaſe the variety. They are raiſed in abundance in all the public nurſeries for ſale.

They may be tranſplanted almoſt any time in open weather from October to March, in any common ſoil and ſituation, and from a few plants of each ſort they will ſoon abundantly encreaſe the ſtock by ſuckers, &c. and as to culture, obſerve of the *Syringa Vulgaris*, or common Lilac in particular, that as it generally throws out numerous ſuckers annually, they ſhould be taken off accordingly, otherwiſe they will ſoon over-run the ground near them, and prevent the mother plant from flowering in due perfection.

*Method of Propagation.*

The propagation of both the ſpecies, and their varieties, is moſt eaſily effected by ſuckers, and layers; alſo by ſeed. But this firſt ſort in particular throws out numerous ſuckers, and produces alſo plenty of ripe ſeed for ſowing.

By

By Suckers.—Numerous ſuckers riſe annually from the roots, though generally more abundantly from the firſt than ſecond ſpecies; and by which all the ſorts may be moſt readily propagated; taking them up any time from autumn till ſpring in open weather, with roots to each, and plant them in nurſery-rows two feet aſunder, to remain for a year or two, or till wanted for final tranſplantation.——See SUCKERS.

By Layers.—Layers of all the ſorts will readily grow, and form proper rooted plants in one year; chuſing the young pliable ſhoots in autumn, and lay them in the common way; they will be well rooted by autumn following, and ready for planting off in nurſery-rows; as directed for the ſuckers.

By Seed.—The firſt ſpecies, and varieties, ripen plenty of ſeed annually in autumn; and by which all the varieties may be raiſed, all of which are generally permanent, or retain their difference from ſeed; which ſhould be ſowed in October or November in a bed of common earth, either broadcaſt or in drills, and covered half an inch deep: they will come up in the ſpring, and in ſpring after the ſeedling plants may be ſet out in nurſery-rows two feet aſunder; and one diſtant in the rows, to have two or three years growth, when they will be fit for the ſhrubbery.

---

# T.

TAGETES, African and French Marigold.

This genus is compoſed of noted herbaceous tender annuals, of the flowery tribe, for adorning the pleaſure-ground in ſummer; they riſing with large branchy ſtems, and full heads, two or three feet high, ornamented with pinnated leaves, and all the ſtems and branches crowned with large, compound, radiated flowers.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX is ſimple, monophyllous, pentagonous, and quinquedented. COROLLA, is compound and radiated, conſiſting of numerous tubular, quinquefid, hermaphrodite florets in the diſc, and ligulated female florets in the radius or circumference. —STAMINA, in the hermaphrodite florets, five very ſhort filaments, with cylindric antheræ. — PISTILLUM, an oblong germen, filiforme ſtyle, having a bifid reflexed ſtigma.—PERICARPIUM, none; each floret ſucceeds to a ſingle linear compreſſed ſeed, crowned by five acuminated, erect, unequal ariſtæ.

There are but three ſpecies of *Tagetes*, two of which only are common to England, each comprehending many varieties; all of them tender annuals, and generally require the aid of hot-beds to raiſe and forward them at firſt, planting them out afterwards in the open ground to grow to perfection; which they attain in July and Auguſt, producing a great profuſion of flowers, both ſingles and doubles; but the latter are conſiderably the moſt ornamental, they growing large, and full to the very centre, appearing both conſpicuous and ornamental, for two or three months in autumn, having different properties in the reſpective varieties, in reſpect to plenitude, colour, and variegations; but have moſtly a very diſagreeable odour.

The ſpecies are,

1 TAGETES *erecta.*

*Upright Mexican Tagetes, commonly called African Marigold, or African*] Riſes with an erect, firm, ſingle ſtem, branching erectly all around near a yard high; having large pinnated, light-green leaves, of many pair of narrow lobes; and all the branches terminated by large, compound, yellow flowers, one on each peduncle, exhibiting different properties in the varieties.

*Varieties are*] Lemon-coloured, or pale yellow-flowered African.——Deep yellow-flowered.——Orange-coloured.——Sweet-ſcented.—

ſcented. —— Dwarf, &c.——All of which varieties furniſh both ſingle and double flowers; the doubles being large, full, and ſwelling, rendered ſo by different modes of impletion, ſuch as—Radiated doubles, rendered double by the impletion or multiplication of the plane florets of the radius.—Diſcous doubles, rendered full by the elongation and leſs profound diviſion of the hollow florets in the diſc—Fiſtulous, or quilled doubles, having all the florets appearing fiſtulous or hollow like a quill—Plane doubles, having all the florets plane or flat—Waved doubles, having all the florets waved—Common ſingle-flowered, having plane florets in the radius, and numerous ſmall tubular florets in the diſc. See the *Characters*, and COMPOSITUS FLOS.

All theſe varieties being ſpecies of the *Tagetes erecta*, they riſe with erect, firm ſtalks and branches, as in the ſpecific deſcription, producing numerous flowers in regular ſucceſſion, from June or July until October, ſucceeded by abundance of ſeed in autumn.

2 TAGETES *patula*.

*Spreading Mexican Tagetes, commonly called French Marigold*] Riſes with ſubdivided ſpreading ſtalks and branches, two feet high, large pinnated deep-green leaves, and at the ſides and ends of the branches numerous, moderately large, compound, radiated flowers, yellow, crimſon, and variegated, in the different varieties.

*Varieties are*] Pale yellow-flowered. —— Deep yellow-flowered —— Golden yellow-flowered— Crimſon-coloured. — Variegated crimſon and yellow, conſiſting of many beautiful variegations in different varieties.—— Striped, crimſon, and yellow.—And of each of which colours there are Single-flowered. Double-flowered — Large-flowered —Small-flowered— Sweet-ſcented, and dwarf French Marigold.—All of which riſe with ſubdivided ſtalks, of very branchy ſpreading growth, producing a great profuſion of flowers from the ſides and ends of the branches, in ſucceſſion, from June or July, until November; but the double, the variegated, and the ſtriped ſorts, are the moſt beautiful; likewiſe ſome of the variegated and ſtriped ſingles are remarkably elegant in their variegations, and richneſs of colours; all the ſorts producing great plenty of ripe ſeed in autumn.

Both theſe ſpecies of *Tagetes*, and all their numerous varieties, are herbaceous annuals, riſing from ſeed in ſpring, obtain full growth in July, flower and produce ſeed in autumn, and wholly periſh, root and top, in October or November.

They being natives of Mexico, are conſequently of ſomewhat tender quality here; but have been long reſidents of the European gardens, as ornamental flowery plants; raiſing them annually from ſeed in ſpring, generally in a hot-bed; thence planted into the full ground, &c. in May or June, where they flouriſh in great perfection, till killed by the froſt.

The flowers of both the ſpecies and reſpective varieties, are large, and very conſpicuous; but thoſe of the firſt ſpecies, *Tagetes erecta*, are much the largeſt: and in all the ſorts they are univerſally compound and radiated, each flower being compoſed of numerous ſmaller ones, all within one general calix or cup; which, in their characteriſtic, or common ſingle ſtate, the middle or diſc conſiſts of many ſmall tubular, hermaphrodite florets, and of many plane or flat tongue-ſhaped female florets forming the circumference or radius: but in their multiplied ſtate, they are rendered double by different impletions; ſometimes by the tubular florets of the diſc being enlarged, lengthened, and leſs divided at the brim; and ſometimes the impletion is effected by an encreaſe of the flat florets, in the ray or radius, multiplying inward, and fill the diſc, to the total excluſion of the tubular florets; and in ſome varieties the impletion conſiſts wholly of plane florets; in others, they become wholly fiſtular or quilled, as often obtain in ſome varieties of the firſt ſpecies *Tagetes erecta*.

The different variation of each of theſe two ſpecies, although apt to vary one to the other, that with particular care in ſaving the ſeed of each reſpective ſort, from the very fineſt full flowers and beſt colours, will remain tolerably permanent, and moſtly produce the like kind of flowers in return.

All the ſorts, conſidered as ornamental plants, are eligible furniture for decorating the borders, and other conſpicuous compartments of the pleaſure-ground; alſo to plant in pots for moving occaſionally, to adorn any particular compartment, in aſſemblage with other potted annuals: they will all grow freely in any common ſoil of a garden, and in an open expoſure; and exhibit a very conſpicuous autumnal bloom, in long ſucceſſion; and being properly diſpoſed in aſſemblage, will affect a very ornamental variety

in

in the diverſity of the various forms and colourings of the flowers, in the different varieties.

They therefore being all of the annual tribe, as we already obſerved, that being raiſed from ſeed ſowed annually in the ſpring, about March or April, in a hot-bed, or warm border, &c. as hereafter directed; they will arrive to a proper ſize for planting out towards the middle or latter end of May, or beginning of June, when the weather will have become ſettled or temperate enough to admit of their being planted any where in the full ground, finally to remain to produce flowers and ſeed.

They are all of very free growth, eſpecially after being planted out finally in the full ground, where they require but very little culture.

The firſt ſpecies in particular, and varieties, as they always grow firmly erect, both in ſtem and branches, require but very little trouble after their final tranſplantation.

But the ſecond ſort *Tagetes patula*, divides and ſpreads out wildly near the ground in a rambling manner; it requires to be trimmed up at bottom to a ſingle ſtem, and its branches alſo trimmed occaſionally, to preſerve the head ſomewhat regular, and within due bounds.

*Method of Propagation.*

As to the method of propagation, they are raiſed only from ſeed ſowed every ſpring in March or April, either in a hot-bed, to raiſe the plants to more early perfection, or in a warm border, about the middle or latter end of April, for a later bloom.

By a Hot-bed.—Towards the middle or latter end of March, or beginning of April, you may ſow ſome ſeed of each ſort in any moderate hot-bed either alone, or with other annuals of ſimilar temperament, ſuch as China aſter, common balſamine, marvel of Peru, chryſanthemum, &c. See ANNUAL PLANTS. Having therefore a hot-bed ready, and ſheltered with a frame and lights, or with hand-glaſſes, &c. or in default of either, arched over with hoops, to be covered with mats on nights, which will ſucceed tolerably, if not ſowed before the beginning of April, obſerving, in either method, the hot-bed being properly earthed at top, five or ſix inches deep; then ſow the ſeed of each ſpecies and reſpective variety ſeparate, either in ſhallow drills a quarter of an inch deep, or on the ſurface, and covered with light mould that depth; or may be ſown in pots, and plunged in the hot-bed.

They will ſoon come up, giving occaſional waterings, and admit a large portion of free air to ſtrengthen the plants as they advance; which when about from three to four or five inches high, prick a quantity of the beſt upon another moderate hot-bed four or five inches aſunder, to have about three weeks growth or more to forward them as much as poſſible: aſſiſting them with proper waterings, giving likewiſe occaſional ſhade from the ſun till rooted, and plenty of free air daily; another parcel of the ſame ſeedlings may, about the beginning or towards the middle of May, when the weather is ſettled tolerably warm, be planted out into the full ground, taking opportunity of ſhowery weather; and plant them either at once where they are to remain, or in nurſery-beds, in rows half a foot at leaſt aſunder; being careful to give water directly, repeating it occaſionally in dry weather, together with occaſional ſhade, where convenient, in ſunny days, till the plants are well rooted afreſh. And when thoſe thus pricked out both in the hot-bed, and in the nurſery beds in the open ground, have had three or four weeks growth, or till from ſix or eight to ten or twelve inches high, they may be tranſplanted with balls of earth, without hardly any check by their removal; or if permitted to ſtand till they ſhew bloom ſufficient to diſcover which are double and which ſingle-flowered, and then chuſing only the beſt ſorts accordingly, removing them with a ball of earth about their roots as aforeſaid, into the borders and pots, or other places intended, at from five at leaſt to ten feet diſtance from one another, and diſtribute the different ſorts ſo as to effect diverſity, watering them directly, and at times till freſh rooted.

Or, if intended to plant the whole immediately out from the ſeed-bed into the borders, &c. finally to remain, as often practiſed to ſave time and trouble; and that if you would cultivate only the fineſt ſorts, may plant two or three plants nearly cloſe together in patches, about the borders, the afore mentioned diſtance, or in pots, &c. and as ſoon as they ſhew their flowers large enough to judge of their properties, may clear away the worſt, and leave only one of the beſt ſorts in each patch, or pot.

Likewiſe, when intended to plant any in pots, to adorn ſore courts, &c. always the very

very beſt doubles of the fineſt colours, from among thoſe which have been previouſly pricked out in nurſery-beds, and remained to ſhew bloom, tranſplanting them with balls of earth into the pots, giving plenty of water, and place them in the ſhade till they have taken good root; then remove the pots of plants where wanted.

Raiſing them in the open ground.—In default of hot-beds, &c. may raiſe all the varieties of theſe plants in the full ground, but the ſeed muſt not be ſowed before April, and chiefly towards the middle of that month; chuſing ſome warm rich border, ſow the ſeed either in ſhallow drills near half an inch deep, or all over the ſurface, and covered thinly with earth, or raked in evenly; obſerving, that if the place is defended with any ſpare hand glaſſes, or frames and lights, or even with hoop-arches for the ſupport of mats, it will be of much advantage in affording ſhelter in cold nights; however, this ſowing often ſucceeds tolerably well without any covering, though probably not come ſo forward as thoſe that have occaſional ſhelter.

When the plants thus raiſed are from about three to five or ſix inches high, as formerly noticed in the hot-bed culture, they ſhould be planted out either finally into the the borders, or in nurſery-beds for a little time; then tranſplanted where they are to remain, as before directed.

As to future culture of all theſe plants, after being finally planted out, give occaſional waterings the firſt week or fortnight till they have taken root, as before adviſed; and after being advanced in growth, place ſome ſtakes where needful to the ſtrongeſt large-headed plants, one ſtake to each; likewiſe trim off low ſtraggling branches near the bottom, and long ramblers of the top or head juſt to preſerve a little regularity, more particularly in the *Tagetes patula*, which is apt to ramble conſiderably.

Thoſe planted in pots will require conſtant watering, three times a week at leaſt, or even every morning or evening in very dry hot weather.

*Saving Seed of all the Sorts.*

As to ſaving the ſeed of theſe plants, they ripen abundance in September; but it ſhould be collected only from the fineſt double flowers, to preſerve the reſpective varieties in as true perfection as poſſible, which, without this precaution, are apt to degenerate conſiderably; therefore gather only the prime large heads of ſeed; which, after being ſpread to dry properly, may either be beat or rubbed out, or retained in the heads; putting the whole up in bags or boxes till ſpring, for ſowing.

Always ſave freſh ſeeds every year; for thoſe more than one year old rarely grow.

TAMARINDUS.

Tamarind tree.

It is a large tree of Indian growth, adorned with fine pinnated leaves, and bunches of tripetalous flowers; and is retained here in our ſtoves for variety.

Claſs and order, *Triandria Monogynia.*

*Characters.*] CALIX, four plane, oval, acute leaves, coloured and deciduous.—COROLLA, three oval, plicated, equal, riſing, ſpreading petals, the length of the calix, with room for a fourth and loweſt petal, &c.—STAMINA, three awl-ſhaped, riſing filaments in the ſinus of the calix, arched towards the corolla, and with oval incumbent antheræ.—PISTILLUM, an oblong, pedicelated germen, awl-ſhaped riſing ſtyle, and thickiſh ſtigma.—PERICARPIUM, a long, compreſſed, unilocular pod, having a double bark, and contains generally three angular ſeeds.

There is but one ſpecies, viz.

TAMARINDUS *Indica.*

*Indian Tamarind-tree.*] Riſes with a large trunk, dividing into a very branchy ſpreading head, growing fifty or ſixty feet high, covered with a brown bark; long abruptly-pinnated leaves of ſixteen or eighteen pair of oval lobes, not terminated by an odd one; and at the axillas of the leaves looſe bunches of reddiſh flowers, ſucceeded by ſeed-pods full of an acid pulp, ſurrounding the ſeeds; but do not ripen in England.

The ſeed-pods of this tree are the tamarinds uſed in medicine, &c. being of a pulpy acid nature, excellent to quench thirſt, and allay heat; and are imported hither from the Weſt and Eaſt Indies, preſerved in ſugar.

This tree is a native of the Eaſt and Weſt-Indies, alſo of Ægypt and Arabia; and from which countries it was firſt introduced into the European gardens for variety; where it requires the conſtant protection of a ſtove all the year; ſo muſt be kept always in pots, and continued conſtantly in that department, and

managed as the other woody exotics of the ſtove collection.

It is propagated by ſeeds obtained from abroad, which ſow in ſpring, in pots of light earth, and plunged in a hot-bed or bark-bed in the Stove, &c. where they will readily come up, and when the ſeedlings are three or four inches high, prick them out in ſeparate ſmall pots, giving water and plunge them again in the hot-bed, repeating the waterings, and give occaſional ſhade from the ſun till freſh rooted: and as the plants advance in growth, ſhift them into larger pots, and keep them always in the bark-ſtove.

TAMARIX.

Tamariſk-tree.

Conſiſts of two hardy deciduous tree and ſhrub kinds, for variety in the ſhrubbery compartments, garniſhed with narrow finely-divided leaves, and numerous ſmall pentapetalous flowers in looſe ſpikes at the ends of the branches.

Claſs and order, *Pentandria Trigynia.*

*Characters.*] CALIX is obtuſe, divided into five obtuſe erect ſegments, and permanent.—COROLLA, five oval, concave, ſpreading petals.—STAMINA, five or ten capillary filaments, having roundiſh antheræ.—PISTILLUM, an acuminated germen, no ſtyle. but three oblong feathery revolute ſtigmas.—PERICARPIUM, an oblong, acuminated triquetrous, trivalved, unilocular capſule, having numerous ſmall downy ſeeds.

There are only two ſpecies, the one ſomewhat of the tree kind, the other a ſhrub, both deciduous hardy exotics, and remarkable for one producing pentandrous, and the other decandrous flowers; and both of which are very ornamental.

The ſpecies are,

TAMARIX *Gallica.*

*Gallican or French Tamariſk.*] Grows fourteen or ſixteen feet high, with ſlender ſpreading irregular branches, covered with reddiſh and brown bark, narrow finely-divided leaves, having the indentures imbricated, or lie over one another like ſcales of fiſh, and numerous ſmall, pale-red, pentandrous flowers in looſe ſpikes at the ends of the branches.

TAMARIX *Germanica.*

*German Tamariſk.*] Grows eight or ten feet high, branching erectly, covered with a yellowiſh bark, ſmall, divided, ſcaley, light-green leaves, and numerous, larger decandrous flowers in looſe ſpikes at the ends of the branches.

Both theſe ſpecies of *Tamarix* begin flowering in July, and as they are produced numerouſly towards the ends of all the branches in large looſe ſpikes, they appear very conſpicuous and ornamental; for though the flowers are ſeparately ſmall, they are very numerous, and cloſely placed in each ſpike; and which in the firſt ſpecies have each but five ſtamina, (*pentandria*), and in the ſecond ſpecies ten ſtamina, (*decandria*), each flower ſucceeded by oblong three-cornered capſules, full of downy ſeed, rarely ripening in England.

Theſe ſhrubs are proper ornaments for decorating the ſhrubbery, and all hardy deciduous plantations; as they exhibit a very conſpicuous variety, both in their beautiful foliage, and fine ſpikes of flowers.

They will ſucceed in almoſt any ſoil and ſituation; and may be had at the public nurſeries; and being in poſſeſſion of a few, may ſoon encreaſe them plenteouſly as below.

*Method of Propagation.*

They are propogated the moſt readily by cuttings; alſo occaſionally by layers; though they generally grow very freely by cuttings.

By Cuttings.—They will readily grow by cuttings of the young ſhoots; and the proper ſeaſon for planting them is almoſt any time from October till February or March, in open weather; chuſing therefore a quantity of cuttings, young ſhoots of the year, and plant them in a ſhady border, or any moiſt ground, in rows a foot aſunder, they will be well rooted by the following autumn; when, if neceſſary, they may be tranſplanted in wider rows, and in two or three years they will be ready for the ſhrubbery.

By Layers.—The young ſhoots are the proper parts to lay, and the autumn or early part of winter is the ſeaſon for laying them; which perform by ſlit-laying, and let them remain a year; then examine them, and plant off ſuch as are rooted in nurſery rows till wanted.

They may alſo be raiſed from ſeed ſowed in a moiſt border as ſoon as it can be obtained.

TAMUS.

Black Briony.

Two hardy, herbaceous, climbing perennials, compoſe this genus, ſometimes raiſed for variety in the pleaſure-ground, and for medical uſes; are volubilate climbers, riſing by

by ſupport many feet high, garniſhed with heart-ſhaped and trifid leaves, and bunches of apetalous dioecious male and female flowers of no beauty.

Claſs and order *Dioecia Hexandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, the males having a ſix-leaved cup, and the females a monophyllous one divided into ſix parts.—COROLLA, no petals.—STAMINA, ſix ſimple filaments in the males, with erect antheræ.—PISTILLUM, in the female flowers, an oblong germen under the calix, cylindric ſtyle, having three reflexed emarginated ſtigmas.—PERICARPIUM, an oval trilocular bacca, having two globular ſeeds.

There are but two ſpecies, one an inhabitant of England, &c. among hedges and buſhes, and the other of the iſland Crete; are both large fleſhy-rooted plants, perennial in root, but with annual ſtalks.

1 TAMUS *Communis.*

*Common Black Briony.*] Hath a very large, thick, fleſhy root, covered with a blackiſh brown ſkin; ſending up long, twining, climbing ſtalks, winding round any ſupport ten or twelve feet high, heart-ſhaped, undivided, ſmooth leaves; and long bunches of white flowers from the ſides of the ſtalks, ſucceeded by oval red berries.

It grows wild under hedges, &c. in England, but is ſometimes admitted in gardens as a climber for variety; and is eſteemed of great efficacy in medicine.

2 TAMUS *Cretica.*

*Cretan Black Briony.*] Hath a large, fleſhy root, twining, climbing ſtalks, mounting by ſupport ten or twelve feet high; trifid, or three-lobed leaves, and bunches of whitiſh flowers at the ſides of the branches, ſucceeded by red berries.

Both the ſpecies flower in June and July; the flowers are ſmall, and without petals; and are ſucceeded in the female plants by berries ripening to a red colour in Auguſt; each having two ſeeds. See the *Characters.*

They are both hardy perennials that are abiding in root, producing new ſtalks annually in ſpring; will grow any where in the full ground under ſhrubs and buſhes; and a few of each ſort may be introduced in the herbaceous collection for variety and obſervation, in thickets, woods, and wilderneſs plantations, among other climbers; and may be there raiſed both from ſeed and roots, planted at once, where they are to remain near the ſhrubs and buſhes, and ſuffered to run and climb over their branches, and any adjacent ſupport.

Some may alſo be cultivated in any bye place for medical uſe, particularly the firſt ſort, as being the moſt common and the moſt eaſily obtained, either the ſeed to ſow, or roots to plant, as below.

Both the ſpecies are eaſily propagated by ſeed, and by parting the roots.

By Seed.—The berries ripen in autumn, which ſhould be ſown ſoon after, that they may more certainly grow the firſt ſpring. Sowing ſome at once where they are to remain in patches between ſhrubs, &c. four or five ſeeds in a place half an inch deep; others may be ſowed in beds, either to remain, or for tranſplantation.

By parting the Roots.—The old roots often furniſh off-ſets, which ſhould be ſlipped off early in autumn or ſpring, and planted at once where they are to remain.

TAN, or TANNER'S BARK, for making hot-beds, called bark-beds.

Tanner's Bark, commonly called ſimply Tan or Bark, is the Bark of the oak-tree, peeled therefrom when felled in the woods for timber, of which there are generally great falls made every ſpring, when all the bark is detached for the tanner's uſe in tanning of leather, being previouſly chopped or ground to pieces: and after being uſed for that purpoſe, and caſt out of the tan-vats, becomes a valuable material in gardening, for making thoſe kind of hot-beds commonly called bark-beds, which are conſiderably the moſt effectual hot-beds in uſe, for the culture of moſt kinds of tender exotics, that require aid of artificial heat in this climate all the year in ſtoves, &c. being generally made in an oblong pit or cavity ſix or eight feet wide, and three deep, the length at pleaſure, (ſee BARK-BED and STOVE); and the hot-bed being, in ſubſtance, the ſame width and depth, it produces a very ſubſtantial, tho' moderate, uniform, and durable heat, not ſo apt as dung hot-beds to heat vehemently, and endanger burning the plants, nor ſend up a noxious ſteam; and the heat is of three times longer duration, and more eaſily managed; for a Bark hot-bed will ſupport its heat near a year, with the aſſiſtance of a little freſh Bark added every three or four

months, forking up the old and new together each time. See BARK-BED and STOVE, &c.

Therefore this valuable material Tan or Bark for the purpoſe of making hot-beds, is the caſt-off Tan of the tan-yards; which, however, they preſerve in ſtore with the utmoſt care for ſale to the gardeners, who now, ſince ſtoves have become ſo common almoſt every where, fetch it far and near, which is ſold at per buſhel, or cart, or waggon-load; but generally about London is ſold at ſeven and ſix pence per load of ſixty buſhels, being careful to have that which is as freſh out of the tan-vats as poſſible, and that of proper quality, for there are different ſorts, ſome being chopped or ground moderately large, ſome middling, and ſome cut very ſmall, to make it go the farther for particular purpoſes of tanning, though not near ſo proper for the gardener's purpoſe as the middling or larger ſort; but the largeſt of all heats the moſt violently, the middling more moderate and durable, and the ſmall ſort ſoon becomes earthy, and declines its heat; ſo that the middling Tan is preferable for general uſe: however, as there is now ſuch an univerſal demand for this article, the deſired ſort is not always to be readily obtained; therefore we are often obliged to put up with a mixture of all ſorts.

But for the particulars reſpecting the choice and preparation of the Tan or Bark, and method of forming it into a hot-bed, and management thereof, ſee BARK-BED, BARK-PIT, FORCING-FRAME, and STOVE.

## TANACETUM.

Tanſey.

This genus compriſes herbaceous and ſhrubby perennials for the kitchen-garden, pleaſure-ground, and green-houſe collections, all of upright growth, from two or three to eight or ten feet high, garniſhed with bipinnated, pinnated, and entire leaves, in the different ſpecies; and the branches terminated by numerous compound flowers, in umbellate and corymboſe bunches.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, a compound flower, having a hemiſpherical, imbricated general cup.—COROLLA, numerous tubular, quinquedented, hermaphrodite florets in the diſc, and trifid female florets in the radius.—STAMINA, five ſhort capillary filaments, with cylindric antheræ, in the hermaphrodite florets.—PISTILLUM, an oblong germen, ſlender ſtyle, having in the hermaphrodites a bifid revolute ſtigma, and two reflexed ſtigmas in the females.—PERICARPIUM, none; a ſingle ſeed in each floret, placed on the convex naked receptacle.

There are about eight ſpecies of *Tanacetum*, though not above five or ſix eſteemed for culture in our gardens; three of which are hardy, herbaceous perennials for the full ground, and three are of ſhrubby growth for the green-houſe.

*Hardy herbaceous kinds.*

Under this head is compriſed the common Tanſey with varieties, Coſtmary or Alecoaſt, and Siberian Tanſey; all hardy, fibrous-rooted perennials, abiding in root, but with ſtalks riſing every ſpring and decaying in autumn.

1 TANACETUM *Vulgare.*

*Common Garden Tanſey.*] Hath a fibrous, tough, creeping root; upright channelled ſtalks, branching erectly two or three feet high; large, bipinnated, cut, ſerrated leaves, of a ſtrong agreeable odour; and all the ſtalks and branches crowned with umbels of yellow flowers in July and Auguſt.

*Varieties.*] Common plane-leaved Tanſey. — Curled-leaved. — Variegated-leaved. — Scentleſs Tanſey.

The common ſort grows wild in England, &c. by road ſides, and on the borders of fields, and ſides of banks, &c. but which, and its varieties, have been long employed in our gardens, both as culinary and medical herbs; and ſometimes as ornamental plants: but for the latter purpoſe the curled-leaved, and variegated ſorts merit the moſt reſpect; the curled ſort in particular having very large thick leaves, moſt beautifully curled, appearing double as it were, and is of a heightened grateful fragrance; which therefore, together with the variegated ſort, demand a place in every ornamental collection, where they will exhibit a very conſpicuous diverſity.

However this herb, for its œconomical uſes in the kitchen and medicine, merits culture in every garden, the leaves being ſometimes uſed in ſallads while young and tender in the ſpring, and for making Tanſey-cakes, puddings, &c. and the leaves, ſeeds, and flowers, are ſaid to be a certain remedy to deſtroy worms in the human body.

This herb, therefore, merits culture in every kitchen-garden, planting ſlips of the

root

root in beds, in rows a foot aſunder, where it will abide many years.

2 TANACETUM *Balſamita.*

*Balſamita Major, commonly called Coſtmary or Alecoaſt.*] Hath a thick, fibrated, fleſhy, creeping root; upright, round, branchy ſtalks, a yard high; oval, entire, ſerrated leaves; and the ſtalks and branches terminated by corymboſe bunches of deep-yellow flowers in Auguſt.

It is an odoriferous plant, formerly in much eſteem both as a culinary and medical herb, and as ſuch is ſtill cultivated in ſome kitchen gardens, planted as the common Tanſey.

3 TANACETUM *Siberica.*

*Siberian Tanſey.*] Hath a thick, fibrous, creeping root; upright, branchy ſtalks, two feet high; pinnated leaves, having very narrow foliola or pinna, ending in two or three points; and at the axillas and termination of the ſtalks, ſmooth, corymboſe bunches of yellow flowers, in June and July.

All theſe herbaceous kinds are durable in root, but annual in leaf and ſtalk.

*Tender ſhrubby kinds for the green-houſe.*

Conſiſts of three ſhrubby ſpecies, moſtly evergreens, originally from Æthiopia in Africa, and require the ſhelter of a green-houſe here in winter: they riſe with ſhrubby ſtems and branches from three or four to eight or ten feet high; ornamented with pinnated and pinnatifid leaves, and bunches of yellow, compound flowers at the end of the branches.

4 TANACETUM *Suffruticoſum.*

*Under-ſhrubby Æthiopian Tanſey.*] Riſes with under ſhrubby branching ſtems, three or four feet high, pinnated multifid leaves, of many very narrow lobes, ſub-divided into acute parts, and roundiſh bunches of bright yellow flowers at the ends of the branches.

5 TANACETUM *fruteſcens,*

*Shrubby African Tanſey.*] Riſes with a woody firm ſtem, branching ſix or eight feet high; pinnatifid leaves, with ſpear-ſhaped obtuſe entire ſegments or lobes; and roundiſh bunches of ſulphur-coloured flowers at the ends of the branches.

6 TANACETUM *Crithmifolium.*

*Samphire-leaved Shrubby Tanſey.*] Riſes with a ſhrubby ſtem, branching five or ſix feet high; pinnated leaves, with very narrow entire lobes, remote from one another, and corymboſe bunches of yellow flowers at the ends of the branches.

All theſe ſix ſpecies of *Tanacetum*, both herbaceous and ſhrubby kinds, flower very abundantly every ſummer, though not all eſteemed ornamental; but the ſhrubby kinds in particular moſt of all: the flowers of all the ſorts are ſeparately ſmalliſh, but being collected into numerous large umbellate and corymboſe bunches at the top of the ſtalks and branches, appear very conſpicuous; and being compound, each ſeparate flower is compoſed of many ſmaller ones, all within one general cup, (ſee the *Characters*); and are ſucceeded by plenty of ripe ſeed in autumn, more eſpecially the herbaceous kinds.

The three herbaceous Tanacetums are very hardy fibrous-rooted perennials, that proſper in almoſt any ſoil and ſituation, and are of great duration in root, which alſo creeps and ſpreads very conſiderably; by which the plants, propagated abundantly, and encreaſing into large bunches, require trimming or cutting in all round occaſionally, to keep them within moderate bounds, eſpecially the common Tanſey, and varieties. The two firſt ſpecies in particular, are the moſt common in England, and are cultivated in kitchen-gardens as culinary herbs; but more commonly the *Tanacetum Vulgare*; planting ſlips of the root of each ſort in autumn or ſpring, in rows a foot aſunder. They may alſo be all employed to diverſify the compartments of the pleaſure-ground, among other large herbaceous perennials.

And as to culture of theſe herbaceous kinds, it conſiſts principally of cutting down the decayed ſtalks annually in autumn; and as the roots encreaſe faſt into large bunches, ſpreading widely round, they require trimming in, or to be ſlipped occaſionally, which otherwiſe are apt to over-run the ground; keeping them clean from weeds, and dig between the plants annually, in common with other ſuch-like perennials.

The three ſhrubby *Tanacetums* being exotics from hot countries in Africa, are ſomewhat tender here, but they only require ſhelter from froſt; ſo muſt be always kept in pots, and depoſited among the green-houſe plants, and treated like other ſhrubby exotics of that collection; in which they will effect a very agreeable variety at all times of the year, but more particularly all ſummer

and

and autumn, when in flower. They generally begin flowering the early part of ſummer, and continue moſtly till the end of autumn; but are rarely ſucceeded by good ripe ſeeds in England.

*Propagation of all the ſorts.*

*Herbaceous kinds.* —— All the herbaceous ſpecies are propagated plentifully by parting the roots; alſo by ſeed.

By parting the Roots.—All theſe ſorts multiply exceedingly by the root, which is the moſt expeditious and ready method of propagating them; which is performed by ſlipping or dividing the roots into ſlips, in autumn or winter, when the ſtalks are decayed; or early in ſpring, before new ſtalks ſhoot forth, planting the ſlips at once where they are to remain: thoſe for the kitchen-garden, ſuch as the common Tanſey, &c. plant in any bed or border a foot and a half aſunder; and thoſe intended for variety in the pleaſure-ground, diſpoſe ſingly here and there, at eligible diſtances, to effect a proper diverſity.

By Seed.—Plenty of ſeed may be ſaved in autumn, which being ſowed in ſpring following, in beds of light earth, broad-caſt and raked in, they will ſoon come up, and in July the plants will be fit to prick out in beds, in rows a foot aſunder; ſome to remain, and others to be tranſplanted in autumn, where required.

*Shrubby kinds.* —— All the three ſhrubby ſorts are all eaſily propagated by cuttings of the branches.

The cuttings may be planted any time in ſpring and ſummer, chuſing the young and moſt robuſt ſhoots, which cut off in proportionable lengths; and if early in ſpring, &c. may plant them in pots of good earth, ſeveral in each, and plunge them in a hot-bed, where they will be rooted, and fit for potting off ſeparately in ſix weeks; or, if in ſummer, the young ſhoots may be planted in the full ground, in a ſhady border, or where they may be ſhaded with mats from the ſun; or planted in pots, and placed in the ſhade, or rather under a garden frame, &c. and ſhaded occaſionally; in all of which methods giving plenty of water, they will readily take root; but thoſe in the hot-bed will be forwardeſt: they however, will all be well rooted the ſame ſeaſon, and ſhould then be tranſplanted in ſeparate pots, then managed as other ſhrubby green-houſe plants. See GREEN-HOUSE PLANTS.

TARCHONANTHUS.

Shrubby African Flea-bane.

It is a ſhrubby ever-green exotic of Æthiopia, for the green-houſe collection; adorned with oval leaves, and compound flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, a compound flower, having a monophyllous, top-ſhaped, ſeptemfid, coloured, permanent cup. — COROLLA, the compound flower is uniform, of many funnel-ſhaped, quinquedented, hermaphrodite florets.—STAMINA, five ſhort filaments, with cylindric antheræ longer than the corolla.—PISTILLUM, an oblong germen, a ſtyle double the length of the flower, and two gaping ſtigmas.—PERICARPIUM, none; a ſingle ſeed in each floret, covered with down, ripening in the permanent calix.

There is but one ſpecies, viz.

TARCHONANTHUS *Camphoratus.*] Riſes with an upright woody ſtem, branching out towards the top, ten or twelve feet high; oblong, oval, downy leaves, white underneath; and purple-violet flowers, in ſpikes at the ends of the branches.

It begins flowering about September, and continues a ſucceſſion of flowers ſeveral months, but does not ripen ſeeds in England.

It is an ever-green exotic from Africa, but has been long introduced into our gardens for variety as a green-houſe plant, as it requires ſhelter in winter; muſt therefore be always cultivated in pots, and managed as other ſhrubby exotics of this collection. See GREEN-HOUSE PLANTS.

The propagation of this plant is eaſily effected by cuttings planted in ſpring or early part of ſummer, in pots, and plunged in a hot-bed, giving occaſional ſhade and water; they will ſoon emit roots the ſame year, and be fit to pot off ſeparately in two or three months. Or cuttings planted in May and June, in beds of common earth, or in pots, and ſhaded with mats or oiled paper ſhelters, or covered with hand-glaſſes, and ſhaded and watered; they will alſo ſtrike root tolerably: obſerving in either caſe, that when tolerably rooted towards autumn, they ſhould be potted off ſeparately, and managed as the other green-houſe plants.

TAXUS.

## TAXUS.

Yew-tree.

It is a famous hardy ever-green tree, of ſtately ſpreading growth; a native of England, and moſt parts of Europe; and an old inhabitant of moſt European gardens, both for ornamental and uſeful hedge-work, and detached trained figures; and is alſo proper for ornamental and timber plantations, in its natural growth; but has been more univerſally cultivated for hedges, and various detached formal devices; as it branches out numerouſly and cloſe to the very bottom, having all the branches very cloſely garniſhed with ſmall, narrow, ever-green leaves, as to render it remarkably well adapted for training into any ſort of hedges, and various kinds of fancy figures, both in cloſe hedge-work, and detached. Hence this tree was univerſally cultivated in great abundance for theſe purpoſes in ancient gardening.——See HEDGES, PLEASURE-GROUND, &c.

Claſs and order, *Dioecia Monadelphia.*

*Characters.*] CALIX, male and female flowers apart, on ſeparate trees, having no calix; but a germ or bud, like a four-leaved cup. —COROLLA, no petals.—STAMINA, numerous filaments in the males, coaleſce in a column below, crowned with peltated depreſſed antheræ, having obtuſe octofid margins, and open on each ſide the baſe, diſcharging the farina or pollen.—PISTILLUM, in the females, an oval, acuminated germen, no ſtyle, but an acute ſtigma.—PERICARPIUM, a red juicy waſting berry, ſucceeds the female flowers, lengthened below, and globular at top, covered by a proper coat below; and includes one oval ſeed, prominent beyond the berry.

There are two ſpecies, but not more than one common in Europe; the other being a native of Japan, is little known in theſe parts.

The common ſort therefore is,

TAXUS *baccata.*

*Common Berry-bearing Yew-tree.*] Riſes with an upright trunk, and very branchy ſpreading head, thirty or forty feet high or more, very cloſely garniſhed with ſmall, narrow, ſtiff, dark-green leaves, growing near together, and very ſmall, apetalous, yellowiſh flowers, male and female, on different trees; in cluſters, at the ſides of the branches, ſucceeded by ſmall, red, pulpy juicy berries, containing the ſeed, ripe in autumn.

*Varieties.*] With very ſhort leaves—Broad ſhining-leaved —— Striped, or variegated-leaved.

The Yew, in all its varieties, is of the dioecious claſs, bearing male and female flowers, moſtly on ſeparate trees; flowering generally in March, but makes an inconſiderable appearance, and are ſucceeded in the females by great plenty of ripe berries, ſerving as food for birds, and to ſow for the work of propagation; as by the berries or ſeed only the tree is generally raiſed, effected in great abundance in a bed of common earth, as directed under the article of their *Propagation.*

This tree, and varieties, are very hardy ever-greens, whoſe verdure aſſumes a dark melancholy hue, of a malignant nature: are all hardy enough to proſper in any common ſoil, even often in the moſt barren, cold ſituations, as may be obſerved in many parts of England, where the tree grows naturally, arriving to a large ſize, fit to fell for timber; which being of a very hard durable nature, is valuable for many uſeful purpoſes: and it is by ſome affirmed, that bedſteads made of Yew, will not be approached by bugs.

But in reſpect, however, to its merit in gardening, it may be employed various ways as an ornamental ever-green; alſo as a foreſt tree, both for ornament and uſe, as before obſerved. Formerly it was greatly employed for hedges; and detached trained figures, in various ornamental forms, in pleaſure-grounds; but now ſeldom uſed in England for theſe purpoſes, ſince all formal works of that nature are moſtly baniſhed our gardens, and inſtead thereof it is employed in its natural ſtate, in ſhrubberies, and other ornamental plantations, principally of the ever-green tribe; being there permitted to aſſume its natural growth, in common with other rural trees and ſhrubs; ſometimes alſo planted as detached ſtandards, in extenſive diſtant opens of graſs ground, in parks and ſides of hills, &c. for variety, and ſuffered to grow in the order of nature; likewiſe is very proper to be introduced as a foreſt tree in all timber plantations, of the ever-green kind particularly, (ſee FOREST-TREES and PLANTATIONS); and for hedge-work,

where

where any internal hedges are required either for ornament or ſhelter, no tree is better calculated, or ſo proper in many caſes, it forming the cloſeſt, even, moderate-growing hedge of any tree of the ever-green collection. It is alſo peculiarly calculated for training into any formal or fancy figure, both in hedge-work, and as detached objects, ſuch as arcades, niches, bowers, pavilions, porticos, alcoves, pedeſtals, obeliſks, pyramids, pilaſters, galleries, and various other architectural devices, as well as the figures of men, beaſts, and birds, as in ancient gardening before noticed; for, by reaſon of its branches and leaves growing exceedingly cloſe, and ſhooting very moderate and regular, they may be readily trained, by clipping, into any form: and as a hedge for ſhelter in nurſery-grounds, &c. to defend the more tender or delicate young plants, no other but a Yew hedge is ſo well adapted. But as an outward hedge for a fence, it is not ſo well calculated as a holly or hawthorn hedge. See HEDGES.

For all of the above purpoſes may this noted tree be moſt eaſily trained, if proceeded with in its minor growth in the nurſery; that if for hedges or any fancy figures, ſuffer the plants to branch away immediately from the very bottom, and trim them with garden ſhears once or twice every ſummer, to form them for the purpoſes intended; and if deſigned for the ſhrubbery and other rural plantations, trim them up a little at bottom to a ſingle ſtem, and ſuffer the head to branch out on all ſides and top diffuſively; likewiſe, if for larger detached ſtandards, trim up the ſtems gradually to elevate them in proportion, and encourage the head to branch out, and diffuſe its branches widely around according to nature.

Yew hedges, and detached fancy figures, were in ſo great repute formerly, when nothing but uniform, regular deſigns in gardening prevailed, that, in pleaſure-grounds particularly, all the diviſions or quarters were ſurrounded with theſe ſort of hedges, &c. ſo as in a manner to ſhut out all other trees, ſhrubs, and flowers, from the ſight of perſons in the adjacent walks; which would otherwiſe have afforded an entertaining variety; and inſtead thereof nothing hardly but Yew hedges were to be ſeen on every ſide: hence many perſons of taſte, conſidering ſuch gardens deſtitute of variety and entertainment, rooted out the hedges by degrees, and laid out the gardens anew in more open rural deſigns, in imitation of nature, exhibiting all the various plants to open view, from the contiguous walks and lawns. So that in conformity to the prevailing rural taſte, in plans or deſigns in gardening, hardly any Yew hedges are admitted by way of ornament, or otherwiſe; or even ſo much as a ſingle detached Yew, trained in any uniform manner. However, ſometimes, in extenſive grounds, Yew hedges, and other formal Yew figures, were ſo judiciouſly arranged, and artfully trained, as to exhibit an air of ornamental grandeur at firſt entrance, eſpecially where they were not too prevalent. Therefore, in pleaſure-gardens of any conſiderable extent, ſome ornamental Yew hedge work, &c. might be admitted in ſome particular open diſtricts, for variety, in contraſt with the rural deſigns; though it ſhould be introduced with great moderation and caution, ſometimes forming the entrance to ſome elegant compartment; and ſometimes the termination or boundary of others, where they may not obſtruct the proſpect, or ſhut out from ſight the view of any deſireable object within the garden; training them, by clipping with garden-ſhears once or twice every ſummer, ſome parts ſtraight, others formed into arches, niches, pilaſters, porticos, and other figures, before noticed. See HEDGES.

Likewiſe, detached Yews for training into various fancy figures, might be thinly diſtributed here and there, and formed by clipping every ſummer into various forms and dimenſions before mentioned, to cauſe variety: for all of which purpoſes, both for formal and rural plantations, young Yew plants may be procured at all the public nurſery-grounds at a moderate rate; or may be eaſily raiſed in great abundance, as hereafter directed.

But ſome perſons reject the Yew, on account of the gloomy mournful aſpect of its verdure, and poiſonous quality; others again admire it for its ſolemn appearance, which effects a remarkably good contraſt with the other more lively evergreens; and as to its baneful effects, it is certain the leaves are of a poiſonous nature, as the name *Taxus*, derived from the Greek, imports; and it is ſaid was formerly uſed in compounding poiſons. Hence

ſome

ſome authors have diſtinguiſhed this tree by the name of TAXUS *lethifera*, the *death-bringing Yew*; and hereby, ſay they, it is looked on as a ſymbol of mortality, and for that reaſon planted in church-yards to remind people of their approaching fate.—It is certain that many accidents have happened to cattle, both horſes and cows, by eating the leaves of Yew, eſpecially the clippings of Yew hedges, which, when they have lain in the ſun a day or two, and half dried, ſome cattle, particularly cows, will ſometimes eat them very greedily; ſo that every one ought to be remarkably careful either to burn the clippings of theſe trees, or put them quite out of the way of cattle, and not careleſly caſt them over the wall or hedge, into lanes, highways, or on rubbiſh heaps, where cattle frequently come.

Young plantable Yews for all the fore mentioned purpoſes, may be procured at moſt of the public nurſery-grounds, at a moderate rate; or may eaſily raiſe them abundantly from ſeed, of a competent ſize, in a few years, for final tranſplantation; i. e. from two or three to five or ſix feet high; though this tree may be removed occaſionally at ſeven or eight feet height, if required, to form an immediate high hedge, &c. for the root being remarkably fibrous, the earth adheres cloſe in a lump, ſo as to admit of removing large plants readily with a ball, to the places allotted them; ſupplying them with due waterings.

*Method of Propagation, &c.*

The propagation of this tree is effected principally by ſeed, which ripen plenteouſly in autumn, and may be ſowed in any bed or border in the open ground, either as ſoon as ripe, or in ſpring. It may alſo be propagated by layers, and cuttings.

By Seed.—It is moſt adviſeable to raiſe the principal ſupply from ſeed; which if ſowed in autumn it will expedite the germenation ſo far, as ſome part will riſe the ſpring following; but if not ſowed till ſpring, they generally all remain in the ground till the ſecond year before they come up, though if the ſeeds or berries are preſerved in earth or ſand till ſpring, then ſowed, they will all riſe together the ſpring after, more plentiful and regular than the autumn ſowings: however, every one may ſuit their own convenience or inclination, in the time of ſowing; and having therefore procured a due quantity of the Yew berries, diveſted of the pulp or mucilage ſow them in beds of light earth, either in ſhallow drills, or ſcattered over the ſurface of the bed, and covered near an inch deep with light mould, out of the alleys, or elſewhere. Being thus ſowed, no farther care is required but keeping the beds clean from weeds, both before and after the plants come up; giving alſo occaſional waterings in dry weather, in ſpring and ſummer, which will forward and ſtrengthen the ſeedlings in their growth: continuing this care of occaſional watering and weeding, let the ſeedlings have two years growth in the ſeed-bed; then in autumn or ſpring prepare ſome ground into four-feet-wide beds, and here plant them out in nurſery rows, a foot aſunder, to remain two, three, or four years; when ſome may either be planted out finally for hedges, if required; others in the nurſery quarter, in rows, two or three feet aſunder, and there trained for the purpoſes they are intended, according to the hints before given.

After growing in the nurſery till they obtain from half a yard to four or five feet ſtature, they may be finally tranſplanted in autumn or ſpring, for their intended purpoſes; they will riſe with a large ſpread of roots, and ſometimes with good balls of earth; and ſhould be planted in their allotted places, as ſoon after removal as poſſible, giving each plant a good watering.

As to future culture, thoſe to be trained in hedges, or for any formal detached figure, muſt be clipped or ſhorn annually, once or twice in the ſummer, (ſee HEDGES); and thoſe in ſhrubberies, and other rural plantations, require only ſome of the lower branches trimmed occaſionally up to a ſingle ſtem; but permit the head generally to ſpread agreeably to its natural mode of growth, except juſt reducing any conſiderable rambling branch, &c.

Remark, as to the ſtriped or variegated Yews and other varieties, that continue them exactly the ſame, the propagation of them ſhould generally be effected by layers, or cuttings, as they are rarely permanent by ſeedlings.

By Layers.—Young ſhoots, not more than a year or two old, being laid in ſpring, ſummer, or early in autumn, many of them will root, and in one or two years be fit for planting off into nurſery lines.

By Cutting, or Slips.—In March or April, or end of Auguſt, or early in September, ſlip off a quantity of the one year's ſhoots, diveſt them of the lower leaves, and plant them in a ſhady border thick together, in ſmall trenches, giving water at planting and afterwards occaſionally, in dry hot weather; they will be well rooted in two years, fit for tranſplantation into wider nurſery rows.

TERRACE, (from *Terra* the Earth.)

A Terrace-walk.

In gardening, a Terrace is a raiſed bank of earth, &c. regularly formed in an oblong manner to any length, broad enough to admit of a ſpacious level walk at top, and elevated ſomewhat conſiderably above the level of the general ſurface; having the ſides uniformly ſloped, and laid with graſs, and the top formed into a flat or level, ſufficiently broad for a graſs or gravel walk, of proportionable width, as hereafter noticed; deſigned in gardens as a high, airy walk, to command a better proſpect of the adjacent places around, both within and without ſide of the garden occaſionally, as well as to enjoy the freſh air in ſummer more freely; and likewiſe a noble Terrace appears very ornamental in the pleaſure-ground.

As to the neceſſary elevation or height of a Terrace-walk, it may be more or leſs as the ſituation admits, or requires, from one foot high to one or two yards; or even three or four yards or more in particular ſituations, and where there are plenty of ſtuff, either acquired or natural, for its formation; allowing breadth in proportion, from five to thirty or forty feet, and extended to any length required, or as may be convenient: for Terraces are ſometimes formed on ſome naturally high, riſing ground, to ſave as much trouble as poſſible, in bringing ſtuff from a diſtance; and is ſometimes raiſed wholly of forced materials.

As to the proper ſituation in a garden for a Terrace, this may be varied as the natural ſituation of the place may require; though in ancient gardening Terraces were more common than at preſent; ſome deſigned both for ornament and grand elevated walks, as being conſiderably raiſed with noble ſloping banks, having ſpacious walks at top for occaſional walking; others being intended only as a moderately-raiſed walk, ſometimes extending in a line from the front of the manſion, or conducted round ſome grand open diviſion, &c.

Sometimes, however, a grand Terrace-walk is formed next the houſe, ranging either parallel to the front, or to one or both wings; or extended in a perpendicular line outward from the front of the main houſe to ſome conſiderable diſtance; and ſometimes are continued both ways; the latter generally much leſs elevated than the former.

Sometimes alſo a Terrace-walk is carried round the boundary of a lawn, or other open diviſion; others, ſometimes contrived at the outer verge of the ground, or at the termination of ſome particular compartment.

Sometimes alſo a moderately elevated Terrace is carried almoſt all round the outward boundary of the pleaſure-ground, to command a more advantageous proſpect of the open country.

In reſpect to form, a Terrace is always broader at the baſe than the top, and extended lengthways to any diſtance required; having the ſides regularly ſloped, of more or leſs acclivity, as the width, height, and ſituation admit or require. Sometimes both ſides are ſloped, and ſometimes only one ſide is ſloped, the other perpendicular, and faced with a ſubſtantial wall, &c. or by being formed againſt the ſide of a hill, or ſome naturally riſing ground; in either caſe is finiſhed always broad enough at top to admit of a proper walk; likewiſe, in ſome naturally-elevated ſituations in particular, Terraces are ſometimes formed one above another in two or more ranges, each having its ſeparate ſide ſlopes, and elevated walk; in all of which the ſlopes are neatly laid with graſs, and the walk at top is occaſionally of graſs or gravel.

The aſcent of entrance to a Terrace-walk, is ſometimes formed by an eaſy acclivity of a graſs or gravelled ſlope; and ſometimes by a grand flight of ſtone ſteps.

Where a naturally-riſing ground, of ſome conſiderable elevation, occurs in a proper ſituation, or on the ſide of a hill, it is an eligible opportunity for forming a grand Terrace with the leaſt expence and trouble, by not requiring the addition of ſo much foreign aſſiſtance in bringing earth and rubbiſh, as when raiſed entirely on a perfect level, wholly of forced earth, brought from another place for that purpoſe; or where there are any excavation of ground intended to form ha-has, pieces of water, &c. the excavated ſtuff might

might be employed in forming a Terrace, &c. where required.

In proceeding to form a garden Terrace, the baſe muſt be ſtaked out wider than the intended width at top, for the walk, in order to admti of the aſcent of ſlopes being moderate.

And in its formation, all the forced earth and rubbiſh muſt be well rammed from time to time as it is applied, in order to render the whole equally firm, that it may not ſettle out of form after being finiſhed; the ſlopes of which may either be laid with turf, or ſowed with graſs-ſeed.—See GRASS.

TETRAGONIA, *Tetragonia.*

Comprehends ſhrubby and herbaceous ſucculent perennials of Africa, for the greenhouſe collection; conſiſting of two ſpecies only, both of ſomewhat decumbent growth, with ſucculent ſtalks, garniſhed with ſmall, narrow, ſucculent leaves, and apetalous flowers at the ſides of the branches.

Claſs and order, *Icoſandria Pentagynia.*

*Characters.*] CALIX, four oval, plane, deflexed, coloured, permanent leaves.—COROLLA, no petals.—STAMINA, about twenty capillary filaments, ſhorter than the calix, having oblong, incumbent anthera.—PISTILLUM, a roundiſh, quadrangular germen, under the calix, four awl-ſhaped, recurved ſtyles longer than the ſtamina, crowned with long hoary ſtigmas.—PERICARPIUM, a large leathery, tetragonous, cruſtaceous capſule, with four longitudinal, narrow wings, or borders; and contain one quadrilocular hard ſeed, or nut, with oblong kernels.

The ſpecies are,

1 TETRAGONIA *fruticoſa.*

*Shrubby Tetragonia.*] Hath ſlender, ligneous, ſucculent, grey ſtalks, branching numerous, and ſtragglingly, four or five feet long, inclining to the ground, unleſs ſupported, and full of cryſtaline drops; very narrow, ſmall, fleſhy leaves, in cluſters, beſpangled alſo with pellucid glittering pimples, and greeniſh and yellow flowers, by two or three together, along the ſides of the branches, in July and Auguſt, ſucceeded by large tetragonous capſules, ripening ſeeds in winter.

2 TETRAGONIA *Herbacea.*

*Herbaceous Tetragonia.*] Hath a remarkably thick, fleſhy root; herbaceous, weak, trailing ſtalks, garniſhed with ſmall, oval, plane, ſucculent leaves, and bright yellow flowers, along the ſides of the branches, in February or March; ſometimes ſucceeded by ripe ſeeds in England.

Both theſe ſpecies of *Tetragonia* being exotics from Æthiopia, require ſhelter here in winter; ſo muſt be always retained in pots, and placed among the green-houſe plants, and managed like other ſucculents of that collection; but ſhould be always placed in the moſt airy part of the green-houſe in winter; as they only want protection from froſt, either in that conſervatory, a glaſs-caſe, or garden-frame; and ſhould be but very moderately watered during that ſeaſon.

They are both of procumbent growth, and unleſs ſupported, trail on the ground. The ſhrubby ſort is durable in root, ſtem, and branch, garniſhed with leaves all the year; but the herbaceous kind often die down to the ground, wholly or in part, towards autumn, and ſend up new ſtalks again about the latter end of the ſame ſeaſon, continuing in leaf all winter, &c.

Both the ſorts are retained in moſt of our eminent green-houſes, to encreaſe the variety; and as there is a ſingularity in their general port or habit, particularly the *Tetragonia fruticoſa*, they merit admittance in every curious collection.

They are eaſily propagated by cuttings, and by ſeed.

By Cuttings.—Cuttings of the young branches may be cut off any time in ſummer for planting, which, as being ſucculent, after having lain a few days to dry up the moiſture of the cut parts, may be planted either in pots, and placed under a garden-frame, and occaſionally ſhaded, or plunged in any hot-bed to forward them. Or cuttings planted in a bed of light good earth, in the full ground, will alſo readily take root, allowing ſhade from the ſun at firſt, and occaſional waterings: they will be rooted in ſix weeks, or two months, fit for potting off ſeparately, planting each in a ſmall pot at firſt, and ſhift them into larger as they ſhall require.

By Seed.—Sow it in the ſpring in pots, and plunge them in any moderate hot-bed, which will generally bring up the plants the ſame year, which otherwiſe are apt to remain in the ground till the ſecond ſpring, before they appear. When they, however, come up, inure them by degrees to the full air; and when two or three inches high, prick them ſeparately in ſmall pots, placed in the ſhade all ſummer, and moderately watered

tered and managed as other green-houſe ſucculents.

TEUCRIUM, Tree Germander, including alſo *Polium* and *Marum*, &c.

This genus is compoſed of under-ſhrubby and herbaceous plants, for variety in the pleaſure-ground, green-houſe, and for medicinal uſe, all of very moderate growth, ſome upright, others with trailing ſtalks, garniſhed moſtly with ſmall, ſimple foliage, and ſmall, monopetalous, ringent flowers, in verticillate cluſters, and ſpikes at the ſides and ends of the branches, in the different ſpecies.

Claſs and order, *Didynamia Gymnoſpermia*.

*Characters.*] CALIX is monophyllous, cut half way into five acute nearly equal ſegments, and is perſiſtent.—COROLLA is monopetalous, ringent, with a ſhort cylindric tube, incurved at the top, and with the upper lip erect, and deeply cut into two parts; the lower one into three, with the middle ſegment largeſt.—STAMINA, two long and two ſhort awl-ſhaped filaments, longer than the upper lip, and prominent between the ſegments, crowned with ſmall anthera.—PISTILLUM, a four-parted germen, a filiformer ſtyle, and two ſlender ſtigmas.—PERICARPIUM, none; the four roundiſh ſeeds lodge in the calix.

To this genus is added the *Polium*, and *Marum*, and ſome other genera, each formerly conſidered as a diſtinct genus, but now arranged as ſpecies only of this genus *Teucrium*, which comprehends above thirty different ſpecies; though ſcarcely a quarter of that number common to our gardens, or that have any great merit for general culture, either for uſe or ornament; conſiſting of hardy, ſhrubby, and herbaceous perennials, for variety and ornament in the full ground; and ſome tender kinds for the green-houſe collection.

*Hardy ſhrubby kind.*

Conſiſts of one ſmall, ſhrubby plant, hardy enough to live in the full ground in a warm, dry ſituation.

1 TEUCRIUM *flavum.*

*Yellow ſhrubby Teucrium, commonly called Tree Germander*] Riſes with erect ſhrubby ſtalks and branches, only a foot and a half or two feet high; having ſmall heart-ſhaped, obtuſely-ſerrated, foot-ſtalked leaves, hoary underneath, with the floral leaves concave and entire; and numerous flowers by threes, in whirls, along the upper part of the branches, of different colours in the varieties.

*Varieties.*] Yellow-flowered —— White-flowered.

This ſhrub is durable in root, ſtem, and branches, foliated moſt part of the year, and produces flowers ornamentally in July, ſucceeded by ripe ſeed in autumn.

It is an exotic from Spain and Italy, long ſince introduced into our gardens; formerly kept as a green-houſe plant, but now is ſufficiently naturalized to this climate to ſucceed in the open air all the year, in a ſheltered, dry ſituation; though it is ſtill alſo proper to keep ſome in pots, to move under ſhelter of a frame, or green-houſe, in ſevere winters, by way of a reſerve, in caſe the fully-expoſed plants ſhould be killed by the froſt.

It is eaſily propagated by ſlips, or cuttings of the branches; and by ſeed.

By Slips, &c.—In ſpring or ſummer, ſlips or cuttings of the young ſhoots may be planted either in pots, ſeveral in each, or in a bed or border of good earth; or, to forward them as much as poſſible, a quantity of ſlips may be planted in pots in ſpring, and plunged in a hot-bed; obſerving, in either caſe, to give due waterings, and occaſional ſhade from the ſun till rooted; and in autumn following, they may be tranſplanted in nurſery-rows, for a year or two, and ſome in pots, for occaſional ſhelter in winter.

By Seed —This may be ſowed in April, in a bed of light earth; and they will ſoon come up, and be fit for planting out early in autumn following.

*Hardy herbaceous kinds.*

There are many herbaceous germanders; but the moſt material are the following perennials, all principally of the fibrous-rooted tribe, riſing moſtly with herbaceous ſtalks; both of procumbent and erect growth; ſeldom exceeding a foot and a half long or high; which in ſome are annual, and ſome become ſomewhat ligneous and abiding; are cultivated for variety and obſervation, and ſome as medical plants.

2 TEUCRIUM *Scordium.*

*Scordium, or Common Water Germander.*] Hath creeping perennial roots, ſending up many ſquare, procumbent, or trailing ſtalks, branching diffuſely; oblong, indented, ſerrated, cloſe-ſitting, oppoſite leaves; and ſmall reddiſh

reddiſh flowers, generally two together, from the ſides of the ſtalks and branches, in July and Auguſt.

This is a medicinal herb, and ſmells ſtrongly of garlic.

It grows naturally in marſhy places, in the iſle of Ely, and other parts of England, and moſt parts of Europe; and ſometimes admitted in gardens, in moiſt places, for variety, and as a medical plant.

[3] TEUCRIUM *Scorodonia.*

*Scorodonia, or Wood Sage.*] Hath a fibrous, creeping, perennial root; upright, four cornered ſtalks, a foot and a half high; heart-ſhaped, ſerrated, foot-ſtalked leaves; and racemous cluſters of whitiſh flowers, from the ſides of the ſtalk upward, ranged moſtly towards one ſide, appearing in July.

It grows naturally in woods and thickets in England, &c.

[4] TEUCRIUM *Chamædrys.*

*Chamædrys or Smaller-creeping Germander.*] Hath fibrous, very creeping, ſpreading roots; many four-cornered, very branchy, trailing ſtalks, near a foot long; oval, cuneiform, cut, crenated leaves, on ſhort foot-ſtalks; and reddiſh flowers, growing almoſt in a verticillus, or whirls, round the ſtalk, three on each peduncle; appearing in June and July. —Is a native of Germany, France, &c.

[5] TEUCRIUM *Canadenſe.*

*Canada Germander.*] Hath a fibrous perennial root; upright ſtalks, a foot and a half high; oval, lanceolate, ſerrated leaves; and white or reddiſh flowers, collected in racemous cluſters, terminating the ſtalks, having ſix leaves under each verticillus, or whirl; flowering in July.

[6] TEUCRIUM *lucidum.*

*Shining Germander.*] Hath a fibrous creeping, perennial root; upright, ſmooth, blackiſh green ſtalks, branching diffuſely; oval-oblong, cut-ſerrated, ſmooth, ſhining-green leaves; and purple flowers by pairs, at the axillas of the ſtalks and branches.—Grows naturally in France and Germany.

The following are principally of the *polium* or poly kind, moderately hardy, but rather impatient of ſevere froſt; ſo ſhould alſo keep ſome in pots, to move under ſhelter in winter.

[7] TEUCRIUM *Polium.*

*Polium, or Common Yellow Mountain Poly.*] Hath a fibrated perennial root; herbaceous, trailing, branchy ſtalks, proſtrate on the ground; oblong, obtuſe, crenated, downy, ſeſſile leaves; and the branches terminated by roundiſh heads of yellow and other coloured flowers in the varieties; appearing in June and July.

*Varieties.*] There are many varieties of this ſpecies, diſtinguiſhed by ſome little variation in their growth, having all roundiſh heads of flowers; moſtly, however, either white or yellow.

It grows naturally in Spain and Portugal, &c.

[8] TEUCRIUM *Montanum.*

*Mountain Poly, with Lavender Leaves.*] Hath a fibrous, tough, ligneous root; ſomewhat ligneous, weak, procumbent ſtalks; ſpear-ſhaped entire leaves, hoary underneath; and ſmall white flowers in a corymbus at the termination of the branches, in June and July.

[9] TEUCRIUM *Pyreniacam.*

*Pyrenean Mountain Poly.*] Hath ſlender, trailing, ſomewhat ligneous, hairy ſtalks; wedge-ſhaped, and roundiſh crenated leaves; and flowers produced in a corymbus at the ends of the branches, of different colours in the varieties; appearing early in ſummer.

*Varieties.*] Purple-flowered—White-flowered—Variegated purple and white-flowered.

[10] TEUCRIUM *Pumilum.*

*Dwarf Mountain Poly.*] Hath ſomewhat ligneous, procumbent, ſlender, downy ſtalks, lying on the ground; linear, or very narrow, plane, leaves in quadriſarous cluſters; and reddiſh flowers, collected into ſmall heads, terminating the branches,—in June and July.

[11] TEUCRIUM *Capitatum.*

*Capitated Mountain Poly.*] Riſes with upright, ſomewhat ligneous, branchy ſtalks, a foot high; ſpear-ſhaped, crenated downy leaves; and white flowers collected into round heads at the end of the branches, ſtanding on peduncles; appearing in June and July.

All theſe herbaceous *Teucriums* flower commonly in June and July; the flowers ſeparately ſmall, of the monopetalous ringent kind; produced generally in a ſort of verticillus, or whirls, towards the upper part of the branches: in ſome placed at a diſtance, and in others in cloſe heads or ſpikes; ſucceeded in the firſt three or four ſorts by plenty of ſeed in autumn; but the others do not always ripen ſeeds freely in England.

They are all perennial plants, durable in root; and ſome of the ligneous kinds are alſo

alſo abiding in ſtalk, more particularly ſome of the *Poliums*.

All the ſorts are occaſionally employed in gardens for variety and obſervation; and may be had at moſt of the nurſeries.

The firſt four or five ſorts are very hardy plants, that will ſucceed any where in the full ground, but moſt proſperouſly in a moiſt ſituation; all of which may he propagated abundantly by ſlips of the roots, in autumn or winter; or of the young ſhoots in ſpring and ſummer; alſo by ſeeds.

But the *Polium* kinds are rather a little tender, and ſhould therefore have generally a dry, raiſed, ſheltered, ſunny ſituation, as before obſerved; and ſome ſhould alſo be potted for ſhelter in winter, under a frame, or in a green-houſe.

As to the method of propagating all theſe ſorts, it is either by parting the roots, by ſlips of the branches, or by ſeeds.

The firſt five ſorts may be propagated plentifully, either by ſlipping the roots, in autumn, winter, or ſpring; or by ſlips or cuttings of the young ſhoots in ſpring, or early part of ſummer, planted in a moiſt ſhady place; or by ſowing the ſeeds in a bed or border of common earth in the ſpring.

The *Polium* kinds may likewiſe be raiſed plentifully from ſeed, and by ſlips or cuttings of the ſhoots in ſpring. The ſeed is generally obtained from abroad, which ſhould be ſowed in ſpring in a bed of light earth, a quarter of an inch deep; where the plants will ſoon come up, and be fit to prick out in July or Auguſt; either in nurſery-rows till autumn or ſpring, or planted at once where they are finally to remain.—And as to the propagation by ſlips, it may be performed in April, chuſing the moſt robuſt ſhoots, and plant them in an eaſterly border, giving occaſional waterings and ſhade; and they will be well rooted by autumn for tranſplantation.

*Tender ſhrubby kinds for the green-houſe collection.*

Several of the ſhrubby kinds of *Teucrium*, being exotics of tenderer quality, require ſhelter here in winter of a green-houſe or garden-frame; ſo are commonly retained in pots, and placed among the green-houſe plants, ſerving to encreaſe the variety of that collection; and the following are the principal ſorts thereof in the Engliſh gardens, being all moderate-growing ſhrubby plants, cloſely garniſhed with ſmall ſimple leaves, moſtly of a ſomewhat hoary or downy nature; and flowers growing in the verticillate order.

[12] TEUCRIUM *fruticans*.

*Shrubby or Spaniſh Tree Germander.*] Riſes with an upright, ſhrubby, hoary ſtalk and branches, five or ſix feet high; having oblong-oval entire leaves, ſmooth above, and hoary underneath, placed oppoſite on ſhort foot-ſtalks; and blue flowers at the axillas of the branches, one on each peduncle; appearing great part of ſummer.

*Variety.*] With ſtriped leaves.

[13] TEUCRIUM *latifolium*.

*Broad-leaved Spaniſh Tree Germander.*] Riſes with a ſhrubby downy ſtalk and branches, five or ſix feet high; having broad, rhomboid-ſhaped, acute, entire, hairy leaves, downy underneath; and pale-blue flowers ſingly at the ſides of the branches; appearing moſt part of ſummer.

[14] TEUCRIUM *Marum*.

*Common Marum, or Syrian Maſtick.*] Riſes with an upright ſhrubby ſtalk, and numerous ſlender hoary branches, from about a foot and a half to two or three feet high; having very ſmall oval, entire leaves, pointed at both ends, hoary underneath, and placed oppoſite; and bright-red flowers in cluſters at the ends of the branches, generally ranged on one ſide, having hairy cups; appearing in July and Auguſt, but rarely any ſeeds in England.

This is a fine aromatic, and is an old reſident of our gardens, eſteemed both for its aromatic property; and to effect variety, generally as a green-houſe plant, though it will alſo ſometimes ſucceed in the full ground, if planted in a dry ſheltered ſituation; affording it protection of mats in very ſevere weather.

[15] TEUCRIUM *Maſſilienſe*.

*Marſeilles Under-ſhrubby Germander.*] Riſes with upright, ſuffruticoſe, or under-ſhrubby ſtalks, about a foot high; oval, cut-crenated, rough, hoary leaves; and purple flowers in erect cluſters, terminating the ſtalks; appearing in July, ſucceeded by ripe ſeed in autumn.

All theſe ſhrubby germanders under this head (Green-houſe kind) are univerſally perennial, or durable in root, ſtem, and branches; and generally retain their leaves moſt part of the year, flowering abundantly every ſum-

ſummer, but rarely ripen good ſeeds in England.

As all theſe green-houſe ſorts are exotics from diſtant warm countries, require to be ſheltered here in winter from froſt; and therefore muſt generally be cultivated in pots, in order to be moved into a green-houſe or garden-frame, during the winter, and managed as other green-houſe ſhrubs, (ſee GREEN-HOUSE PLANTS); but ſome may alſo be planted in the full ground, in a warm dry ſituation, where they will often ſtand through our moderate winters tolerably well; but are liable to ſuffer by ſevere froſt, which renders it neceſſary to treat the principal part generally as green-houſe exotics.

The propagation of all theſe tender ſhrubby kinds, is by ſlips, or cuttings of the young ſhoots of the branches in ſpring, and early part of ſummer, as directed for the firſt ſpecies (*Teucrium flavum*); and when rooted, plant moſt of them ſingly in pots for removing to occaſional ſhelter in winter, and managed as before hinted; others plant in the open air, in a dry warm expoſure, to take their chance.

## THALICTRUM.

Meadow Rue.

This genus conſiſts wholly of hardy, herbaceous, fibrous-rooted perennials, ſome of which are cultivated in gardens for variety and ornament, riſe moſtly with upright ſtalks annually, adorned with many-lobed leaves, and ſmalliſh tetrapetalous flowers, generally crowning the ſtalks in paniculated bunches.

Claſs and order, *Polyandria Polygynia.*

*Characters.*] CALIX, none. — COROLLA, four roundiſh, concave petals that ſoon fall off.—STAMINA, numerous compreſſed filaments, broadeſt above, and terminated by oblong erect antheræ. — PISTILLUM, numerous roundiſh pedicellated germina, having thickiſh ſtigmas.—PERICARPIUM, none. —Numerous oval ſulcated ſeeds in a head.

There are twelve or fourteen ſpecies, and the moſt noted of which in our gardens are the following, retained in the pleaſure-ground for variety; all of which have perennial roots, moſtly fibrated and creeping; and ſend up erect herbaceous ſtalks annually, in ſpring, which conſtantly decay to the ground in autumn.

[1] THALICTRUM *flavum.*

*Greater Yellow Thalictrum, or Common Meadow Rue.*] Hath a thick, fibrous, creeping, yellow root; ſending up ſeveral round, furrowed, leafy ſtalks, five or ſix feet high; garniſhed with many-lobed leaves, having moſt of the lobes cut into three parts; and numerous whitiſh flowers terminating the ſtalks in many paniculated bunches, ſtanding erect.

*Variety.*] Montpelier yellow-flowered, called *Thalictrum Specioſum.*

This ſpecies grows wild in meadows, and other moiſtiſh places, and by river ſides in England, &c. and is ſometimes introduced in gardens for variety.

[2] THALICTRUM *aquelegifolium.*

*Columbine-leaved Thalictrum, commonly called Feathered Columbine.*] Hath a thick fibrous root; upright taper ſtalks, three or four feet high; large leaves compoſed of many lobes, much like the *aquilegia* or columbine; and numerous whitiſh flowers, terminating the ſtalks in large panicles, ſucceeded by ſtraight, triangular, pendulous ſeeds.

*Varieties.*] Green-ſtalked, with white flowers and ſtamina—Purple-ſtalked, with purple flowers and ſtamina.

Is an inhabitant of Helvetia, &c. but has been long in the Engliſh gardens.

[3] THALICTRUM *Cornuti.*

*Canada Thalictrum of Cornutus.*] Hath a fibroſe dark-coloured root; upright, ſmooth, purpliſh ſtalks, three or four feet high, branching towards the top; large many-lobed leaves like thoſe of columbine; and numerous white flowers terminating the ſtalks and branches, in large panicles, each flower having five petals.

[4] THALICTRUM *anguſtifolium.*

*Narrow-leaved German Thalictrum.*] Hath a fibrated root; upright ſtalks, two or three feet high; large pinnated leaves, of many very narrow entire lobes, and numerous ſmall whitiſh flowers in panicles, at the top of the ſtalks.

[5] THALICTRUM *tuberoſum.*

*Tuberoſe-rooted Spaniſh Thalictrum.*] Hath a root hung with many-knobbed tubers; upright, almoſt naked ſtalks, a foot and a half high; ſmall obtuſe leaves, three-parted at the end; and largiſh white flowers, in roundiſh bunches, at the top of the ſtalks; each flower having five petals.

[6] THALICTRUM *minus.*

*Leſſer Meadow Rue.*] Hath ſmall, fibrous, creeping roots; ſlender branching ſtalks, about a foot high; leaves cut into ſix parts; ſmall and whitiſh and yellow flowers, in a nod-

nodding poſition, in looſe panicles, at the top of the ſtalks.—It inhabits moiſt meadows and paſtures in England, &c.

7 THALICTRUM *fœtidum.*

*Fœtid* or *Stinking Dwarf Thalictrum.*] Hath a fibrous creeping root; ſlender, paniculated, branchy, leafy ſtalks, ſix or ſeven inches high; leaves compoſed of many ſmall, indented foliola, having a ſtinking odour; and ſmall whitiſh flowers in looſe panicles, at the top of the ſtalks.——Grows naturally in the ſouth of France, and Helvetia, &c.

8 THALICTRUM *Alpinum.*

*Alpine Dwarf Thalictrum.*] Hath a fibrous creeping root; ſlender, ſingle, almoſt naked ſtalks, about ſix inches high; leaves having ſmall obtuſe lobes, and whitiſh flowers in ſingle cluſters terminated the ſtalks.

All theſe ſpecies of *Thalictrum* generally flower in June and July, except the Alpine ſort, which commonly flowers in April or May; the flowers ſeparately are ſmall, but collected many together in paniculated bunches at top of the plants, each flower having generally four petals, and in ſome ſpecies five, as in their reſpective deſcriptions; and are ſucceeded by ripe ſeeds in Auguſt and September.

They are all very hardy herbaceous perennials, that will ſucceed in any common ſoil and expoſure, in the full ground; though generally are the moſt proſperous in ſhady moiſt ſituations: they are eſteemed, ſome as flowery ornamental plants, others principally as plants of variety, and botanical obſervation; though all the ſorts may be employed to diverſify the pleaſure-ground in any of the open compartments, in aſſemblage with other herbaceous perennials; and are all eaſily raiſed from ſlips of the root in autumn, which will creep exceedingly, and multiply in great abundance.

But the ſecond and third ſpecies are the ſorts that are the moſt commonly known, eſteemed, and cultivated in the Engliſh gardens as ornamental flower plants, they flowering more conſpicuouſly than the others; though the firſt ſort is alſo often admitted in eminent gardens to encreaſe the variety.

The propagation of all the ſorts is very eaſily effected in abundance, by parting the roots in autumn, when the ſtalks decay, or in the ſpring before new ones ſhoot forth; planting the ſlips, the ſtrongeſt where they are to remain, and the weakeſt in nurſery-rows, to have a ſummer's growth, or to remain till wanted.

Likewiſe by ſeed ſowed in the ſpring, in a bed or border; they will ſoon riſe, and the ſeedling plants will be fit to plant out towards autumn following.

THEOBROMA.

Chocolate Nut Tree, &c.

Compriſes two exotic trees of the Weſt Indies. retained here in ſome eminent ſtoves for variety; are adorned with large oblong and heart-ſhaped ſimple leaves, and ſmall pentapetalous flowers, in bunches, at the ſides of the branches.

Claſs and order, *Polyadelphia Pentandria.*

*Characters.*] CALIX, three oval, concave, reflexed, ſpreading deciduous leaves.—COROLLA, five concave, galeated or arched, quinquenervous petals, having each a bifid, horn-like briſtle at top, and a bell-ſhaped nectarium of five oval-lanceolate, connected, ſpreading leaves.—STAMINA, numerous awl-ſhaped filaments in five bodies, terminated by ſo many antheræ.—PISTILLUM, an oval germen, awl-ſhaped ſtyle, and ſimple ſtigma.—PERICARPIUM, a woody, unequal, oblong, or roundiſh fruit, or nut; having many oval fleſhy ſeeds arranged in five cells.

There are only two ſpecies, both of the tree kind, though the firſt is but of very moderate growth, and the ſecond obtains ſome conſiderable ſtature and magnitude.

1 THEOBROMA *Cocao.*

*Cocao or Chocolate Nut Tree.*] Riſes with an upright, robuſt ſtem, only about half a foot thick, branching ten or twelve feet high; large, oblong, entire, oppoſite leaves, near a foot long, and half as broad; and numerous yellowiſh flowers, in bunches, from the ſides of the trunk and branches; ſucceeded by oblong, quinquangular fruit, full of ſeeds, of which is made the chocolate.

This tree inhabits the hot parts of America, where it is alſo attentively cultivated for its fruit, to make the chocolate; being made of the kernels, which are firſt roaſted in a pan, and reduced to powder; then worked with orange water, and formed into a paſte; afterwards mixed with ſugar, aromatic ſpices, and perfume; then formed into rolls or cakes, and exported to Europe, and other different parts of the world.

2 THEOBROMA *Guazuma.*

*Guaz-*

*Guazuma, or Baſtard Cedar of Jamaica.*] Riſes with an upright large trunk, branching numerouſly and ſpreading, thirty or forty feet high; oblong, heart-ſhaped, ſerrated, alternate leaves, four inches long; and numerous ſmall yellowiſh flowers at the ſides of the branches; ſucceeded by roundiſh, tuberculated rough fruit, containing the ſeed.

Both theſe trees being exotics from the hot parts of America, in this country require the indulgence of a ſtove; ſo muſt be kept always in pots, and placed in that conſervatory, and managed as other woody exotics of ſimilar quality. See STOVE PLANTS.

They are propagated by ſeed obtained from abroad, ſowing it as ſoon after its arrival as poſſible, in pots, and plunged in a bark-bed, where they will ſoon come up; and when about three inches high, pot them off ſeparately, and plunge them in the bark-bed in the ſtove; and manage them as other woody exotics of this department.

THERMOMETER.

An inſtrument reſembling a weather-glaſs, for meaſuring and demonſtrating by inſpection the degrees of heat and cold at all ſeaſons, and which proves of great utility in the culture of tender exotic ſtove plants, by ſerving as a guide to regulate the proper degree of heat for ſtoves or hot-houſes, containing ſuch plants; particularly in winter, when fire heat is uſed. See STOVE.

At to the conſtruction of a botanical Thermometer for a hot-houſe, it conſiſts of a long ſlender glaſs tube, or pipe, about two feet long, having a ſmall glaſs ball or globe at the end; and is fixed longitudinally on a braſs or wooden plate or frame, the ſame length, or longer, and four or five inches broad; the glaſs tube and ball being furniſhed with a quantity of coloured liquid ſpirit, which is affected by heat and cold ſo as to aſcend higher or lower in the tube proportionably, a ſcale being marked on the frame along each ſide of the tube, divided into the different degrees of heat and cold; and the ſpirit aſcending by the heat of the internal air, promoted by fire, &c. points out on the ſcale the proper degree of heat required, having the name of ſome remarkable exotic, ſuch as the *anana*, or pine-apple, wrote on the ſcale as a ſtandard mark of the requiſite temperature of heat, ſo as when the internal heat of the ſtove raiſes the ſpirit to that mark, or within five degrees over or under, is the proper temperature for the growth of the *ananas*, and all other tender plants from the hotteſt parts of the world; ſo that the fires requiſite for the ſtove in winter, are to be made ſtronger or weaker, according to the direction in the Thermometer.

Thus a good Thermometer in ſtoves is more particularly uſeful in winter, during the time the fires are made in the flues for warming the air internally; it being generally hung up towards the centre of the ſtove, ſo as the warmth thereof may operate moderately and equally on every ſide, and diſcover the real temperature of the general internal heat, which ſhould be ſupported always nearly equal by the aid of bark hot-beds and real fire, ſufficient to raiſe the ſpirit in the tube to the mark *ananas* aforeſaid, or but a little over or under.

Remarking however, the Thermometer ſhould not only be ſuſpended nearly towards the centre of the ſtove, but alſo out of the ſun, or at leaſt placed with its back thereto, that the glaſs tube and ball containing the ſpirit, may be ſhaded from the ſun-ſhine as much as poſſible; and alſo placed at ſome diſtance from the fire place and flues, ſo as neither the direct rays of the ſun, or heat of the fire, darting immediately on the tube and ball, may affect the operation of the encloſed liquor, and cauſe it to mount conſiderably higher than would be effected by the real general warmth of the air of the ſtove, and be thereby led inadvertently into an error, in ſuppoſing the internal heat to be much ſtronger than it really is, when probably it is not ſtrong enough; which, if often repeated, might in time prove very prejudicial to the plants: therefore this inſtrument ſhould always be judiciouſly placed as above, ſo as to be affected only by the real general warmth of the internal air; and by obſerving this, you may eaſily regulate the ſtove heat at all ſeaſons to ſuch proper temperature as is requiſite for the culture of the plants before mentioned.

That therefore every ſtove ought to be furniſhed with a good botanical Thermometer, as a guide for more certainly determining at all times the neceſſary degree of heat; for in winter, when fires are requiſite, it is eaſy to make them of more or leſs ſtrength, as you ſhall ſee neceſſary, to warm the whole

incloſed air equally, to ſuch a temperature of heat, as to mount the ſpirit in the Thermometer to the degree marked *ananas*, which ſhould be well attended to, and continued always as nearly as poſſible to that ſtandard, or not exceeding five or ten degrees over or under.

Or if the Thermometer ſhould at any time diſcover the fire heat in winter, &c. to be conſiderably too ſtrong, let the fire be immediately leſſened, and open the door of the furnace to cool the flues; alſo, if calm mild weather, admit freſh air moderately, if it ſhall ſeem neceſſary, in order to reduce the heat as ſoon as poſſible, nearly to the proper ſtandard.

Likewiſe in ſummer, in very hot ſunny weather, if the internal heat of the ſtove appears by the Thermometer to be much too powerful in the middle of the day, it is eaſily reduced to the proper temperature, by ſliding open the glaſſes to admit free air, as you ſhall ſee convenient.

THYMUS.

Thyme.

This genus furniſhes the common Thyme, and ſeveral other low aromatic plants, moſtly perennials of ſomewhat ſuffruticoſe or undershrubby growth; ſome valued as noted potherbs, others as medical plants, and ſome for varietyin the pleaſure-ground; riſing with ſlender ſtalks and branches, from about half a foot to a foot or eighteen inches high; adorned with very ſmall leaves, and ſmall ringent flowers in verticillate ſpikes and heads, terminating the branches.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX is monophyllous, tubular, bilabiated, and permanent; having the chaps hairy and cloſed, with the upper lip broad, plane, erect, and tridented, and with the lower one ending in two equal briſtles.—COROLLA, a ſmall ringent petal, having the upper lip ſhort, erect, obtuſe, and emarginated, and the under one long, broad, and tridented, with the middle ſegment the longeſt.—STAMINA, two long and two ſhort filaments, having ſmall antheræ.—PISTILLUM, a four-parted germen filiforme ſtyle, and a bifid, acute ſtigma.—PERICARPIUM, none; four ſmall roundiſh ſeeds lodged in the permanent calix.

There are ſeven or eight different ſpecies of *Thymus*, and of which the following are the moſt material ſorts for general culture; conſiſting of the common Thyme of our kitchen gardens,—*Serpyllum*, or Wild Thyme,—Maſtic Thyme, &c. each compriſing ſome varieties, and are all low, frutiſcent perennials, moſtly of very branchy buſhy growth, and durable in root, ſtem, and branches, and all hardy enough to grow freely in the full ground, in any common ſoil of a garden.

[1] THYMUS *Vulgaris.*

*Common Garden Thyme.*] Hath very fibrey roots; erect, ſlender ligneous ſtems, of very branchy and buſhy growth, a foot high, cloſely garniſhed with ſmall oval revolute leaves, and all the branches terminated by numerous ſmall, whitiſh-purple flowers, in verticilate ſpikes, appearing in ſummer, and ſucceeded by abundance of ripe ſeed early in autumn.

*Varieties.*] Broad-leaved — Narrow-leaved —Variegated or ſtriped-leaved.

It is an inhabitant of rocky places in France and Spain, &c. but all the varieties have been long reſidents of our kitchen-gardens as eminent aromatic pot-herbs, and as medical plants; alſo occaſionally in the pleaſure-ground for variety, and ſometimes as edgings to beds and borders, on account of its cloſe buſhy growth; but its principal eſtimation is for kitchen and medicinal uſes.

[2] THYMUS *Serpyllum.*

*Serpyllum, Creeping Wild Thyme, or Mother of Thyme.*] Hath decumbent creeping ſtalks, ſix or eight inches long, or more; garniſhed with obtuſe, plane leaves, ciliated at the baſe, and the branches terminated by numerous ſmall, purpliſh flowers, growing in heads, appearing in ſummer, ſucceeded by plenty of ripe ſeeds in autumn.

*Varieties.*] Broad-leaved.—Narrow-leaved Broad hairy-leaved — Variegated-leaved — Citron-ſcented, commonly called Lemon Thyme—Greater purple-flowered.

This ſpecies inhabits paſtures, heaths, and commons, in moſt parts of Britain, and other parts of Europe; and is admitted into many gardens for variety, more particularly the variegated ſort, and that called Lemon Thyme, which are ſometimes diſpoſed ſingly about the borders, &c. and ſometimes in pots; and were alſo formerly employed to form edgings; but the Lemon Thyme in particular is in high eſtimation for its agreeable odour.

[3] THYMUS *Maſtichina.*

*Maſtichina, or Maſtich Thyme.*] Riſes with ſlender ligneous ſtalks and branches, a foot long, or more; garniſhed with oval, obtuſe, hoary leaves; and the branches terminated by the flowers in verticillate, downy heads, appearing in June, but rarely ſucceeded by ſeeds in England.

*Varieties.*] White-flowered—Red-flowered.

It is a native of rocky places in Spain, but is an old inhabitant of our gardens, chiefly as a finely-ſcented aromatic, and for variety.

[4] THYMUS *Zygis.*

*Zygis, or Shrubby narrow-leaved Spaniſh Thyme.*] Riſes with low, under-ſhrubby, erect ſtalks; long, very narrow leaves, ciliated at the baſe; and flowers terminating the branches in verticillate ſpikes.

[5] THYMUS *cephalotos.*

*Large headed Portugal Thyme.*] Riſes with low ligneous ſtalks, and ſtiff hoary branches, half a foot long; ſpear-ſhaped hoary leaves, placed oppoſite; and many whitiſh flowers, terminating the branches in large imbricated heads, having oval bracteal leaves.

*Variety.*] With ſmall flowery heads.

All theſe five ſpecies of *Thymus*, and their varieties, are of an aromatic quality, and their chief virtue reſides in the leaves, which impart a very agreeable aromatic fragrance. But the firſt three ſpecies are the moſt noted ſorts in the Engliſh gardens; though the *Thymus Vulgaris*, or Common Thyme, is conſiderably the moſt generally known and cultivated, chiefly for its ſuperior aromatic property, for culinary purpoſes.

They are univerſally perennial, ſomewhat between a ſhrubby and an herbaceous nature, wholly abiding in root and top, generally of ſomewhat buſhy growth; their leaves in general very ſmall, but cloſely placed, and moſtly evergreen: the flowers alſo are very ſmall, monopetalous, and ringent, and collected numerouſly in whirls, either forming ſpikes or cloſe heads, each flower ſucceeded by four ſeeds lodged in the calix. See the *Characters*; and by ſeeds all the ſpecies may be raiſed, as alſo by ſlips and cuttings; and by theſe latter methods only, the varieties are with certainty continued.

As to the uſe in gardens of theſe aromatics, the Common Thyme is in univerſal eſtimation as a pot-herb for various culinary purpoſes; and being eaſy of propagation and culture, merits a place in every kitchen-garden: which alſo, together with the other ſorts, and their varieties, might be introduced in the pleaſnre-ground, in aſſemblage with other ſmall frutiſcent plants, to embelliſh the front of raiſed ſhrubbery clumps, and ſloping banks, &c. placing them detached or ſingly, to form little buſhy tufts; likewiſe ſome plants of the variegated ſorts, and of the Lemon Thyme, may alſo be potted, in order to move occaſionally to any particular compartment, and under occaſional ſhelter in very ſevere winters, to preſerve the ſorts.

But as to the *Common Thyme*, deſigned for kitchen uſe, it ſhould be cultivated in beds, or borders, in rows, half a foot aſunder at leaſt; either the ſeed ſowed where the plants are to remain, or young ſeedling plants previouſly raiſed for planting out; or ſlips of old plants detached with roots, which being planted the above diſtance, they will ſoon increaſe into buſhy plants, proper to gather for uſe; or may be occaſionally planted as an edging in the herbary, &c. and in either method the plants will prove abiding, and multiply exceedingly by off-ſets; and by which the plants may be propagated at pleaſure, by ſlipping them as above, when wanted for increaſe; though it is alſo adviſeable to raiſe a quantity of plants every year or two from ſeed, as the young ſeedlings poſſeſs a ſtronger aromatic quality than the older plants: and in market gardens, where large quantities are required for ſale, ſhould always raiſe a due ſupply annually from ſeed, as practiſed by the London gardeners; which being ſowed in ſpring in a bed of light earth, either broad-caſt and raked in, or in ſhallow drills, as directed below, they ſoon come up, and the plants want thinning in June, to ſix inches diſtance, and will be fit for uſe the following autumn and winter, &c.

In gathering Thyme for uſe, in private gardens it may be cut or ſlipped a little at a time, as it is wanted, not ſtumped too cloſe; but when intended for market, the London gardeners generally pull it up root and all, eſpecially the ſeedling plants, which remain in the bed where raiſed, and ſo raiſe a freſh crop from ſeed annually.

*Method of propagating all the ſorts.*

All the ſpecies of Thymus may be eaſily raiſed from ſeed, and by ſlipping the roots and branches, and by cuttings thereof.

By Seed.—All the ſorts may be raiſed plenteouſly from ſeed; though it is rarely practiſed to any but the firſt ſort, Common Thyme; and March or early in April is the proper ſeaſon for ſowing it; chuſing any light rich, dry ground; which let be properly digged, and the ſurface moderately ſmoothed with the ſpade, becauſe the ſeed is very ſmall, and ſhould not be ſowed too thick, nor covered too deep; this obſerved, let the ſeed be ſowed whilſt the ground is freſh ſtirred, ſowing it either broad-caſt on the ſurface, and rake it in lightly, or ſow it in flat ſhallow drills, and earth it over thinly in proportion: it will ſoon germinate, and the plants will appear in two or three weeks, being careful to keep them well weeded, and give occaſional light waterings in dry weather; and thus by June they will require thinning, to ſix or eight inches diſtance; when, if required, thoſe thinned out may be planted in another place, in rows, ſix or eight inches aſunder, giving water till freſh rooted, obſerving to keep the whole clean from weeds by occaſional hoeing between them in dry days, which will alſo ſtir the ſurface of the earth, and thereby much improve the growth of the plants; and they will arrive to good perfection early in autumn.

Remark, in reſpect to the varieties, that there is no depending on raiſing them the ſame from ſeed; therefore, when intending to propagate any particular varieties, and continue them the ſame with certainty, it can only be effected by ſlips and cuttings as below.

By Slips.—All the ſorts multiply exceedingly both by ſlips of the root and of the branches; the rooted ſlips are the moſt expeditious method, for the old plants encreaſe conſiderably into many off-ſet ſtems, riſing immediately from the root, each furniſhed with fibres; and that by taking up the old plants in the ſpring, &c. and ſlip or divide them into as many ſeparate ſlips as you can, with roots to each, and plant them in beds of good earth, in rows half a foot aſunder, giving water directly, and repeat it occaſionally in dry weather till they have taken root, and begin to ſhoot at top; and thus they will ſoon grow freely, and form good buſhy plants in two or three months.

But ſlips alſo of the branches without roots, will likewiſe ſucceed, if planted, any time from March or April until about Midſummer; obſerving to ſlip off a quantity of the ſtouteſt young outſide ſhoots, of moderate length, and plant them in a ſhady border, in rows four or five inches diſtance, giving due waterings; they will ſoon emit roots, and become good plants by autumn, when they may be tranſplanted to where they are to remain.

By Cuttings. — Cuttings of the young branches grow readily the ſame as ſlips thereof, there being no other difference, than that the cuttings are the young ſhoots cut off with a knife, and the ſlips are ſliped off from the ſide of the branches with the hand only; ſo that the propagating them by cuttings may be performed any time in ſpring, or early part of ſummer, planting them in a ſhady place, and duly watered, they will readily take root, and grow.

Obſerve, as before ſuggeſted, the propagation by ſlips or cuttings is alſo the only method by which the reſpective varieties of the different ſpecies are with certainty continued the ſame, as the plants thus raiſed will be in every reſpect ſimilar to the parent.

## THYRSUS.

A Thyrſe.

One of the modes of inflorescence, or manner of flowering, of the aggregate kind; being many flowers collected in a bunch, or ſort of cloſe panicle, of an oval or egg-ſhaped form, having the lower foot-ſtalks, which are longer, extend horizontally, whilſt the upper ones are ſhorter, and mount vertically, as in lilac and horſe cheſnut, &c.

## THUYA.

*Arbor Vitæ*, or Tree of Life.

This genus furniſhes beautiful hardy evergreen trees, of the coniferous tribe, for adorning the ſhrubbery, and other hardy plantations, being of erect tall growth, very branchy to the bottom; cloſely garniſhed with very ſmall imbricated leaves, and ſmall apetalous male and female flowers ſeparately on the ſame tree.

Claſs and order, MONOECIA *Monadelphia.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant; the males being collected in an oblong, oval amentum, growing oppoſite on the common foot-ſtalk, the florets having an oval concave ſcale for the cup; and the female flowers form an oval cone,

cone, having a ſcale for a cup to every two florets. — COROLLA, ſmall florets, without any petals. — STAMINA, four very ſmall, monadelphous filaments in the males, having the antheræ adhering to the baſe of the calicinal ſcale.—PISTILLUM, in the females a very ſmall germen, ſlender ſtyle, and ſingle ſtigma. — PERICARPIUM, an oblong oval cone, opening longitudinally, compoſed of nearly equal ſcales, convex on the outſide, and obtuſe, each having an oblong ſeed, ſurrounded with a membraneous wing.

There are three ſpecies of *Thuya*, two of which only are common to the Engliſh gardens, being eſteemed fine ornamental evergreens of the tree kind; and which, although exotics, the one principally from America, the other from China, are hardy enough to flouriſh here in almoſt any common ſoil and expoſure, and remain in verdure the year round; are therefore in great eſtimation for all ornamental plantations.

They are both of the very ſmall-leaved kind, with the leaves imbricated, or lying over one another like ſcales.

The ſpecies are,

[1] THUYA *Occidentalis*.

*Occidental, or Common American Arbor Vitæ.*] Riſes with a large upright ſtrait trunk, branching on every ſide irregularly, forty feet high or more, with the branches growing ſomewhat horizontally and ſtraggling; being cloſely garniſhed with very ſmall leaves, placed imbricatim, or over each other, appearing of a dark duſky-green colour; and with male and female flowers apart, at the ſides of the young branches in ſpring, ſucceeded in the females by ſmooth cones, having ſmooth obtuſe ſcales, containing oblong ſeeds.

*Varieties.*] Common American Arbor Vitæ — American ſweet-ſcented — Variegated-leaved.

This tree grows naturally in Canada, in North America, and in Siberia, is of an aromatic and reſinous nature; the leaves emit a ſtrong odour; alſo the wood, which is likewiſe remarkably durable: hence it is ſaid the tree anciently derived the name *Arbor Vitæ*, or Tree of Life.

[2] THUYA *Orientalis*.

*Oriental, or Chineſe Arbor Vitæ.*] Grows with a ſtraight upright ſtem, branching erectly, cloſe, and regular, thirty or forty feet high, very cloſely garniſhed with very ſmall flat leaves, placed imbricatim, appearing always of a bright-green colour; and male and female flowers ſeparately at the ſides of the young branches in ſpring, ſucceeded by rugged cones, compoſed of acute-pointed reflexed ſcales, having ripe ſeeds in autumn, or towards ſpring.

Both theſe trees are natives of diſtant countries, the firſt being of North America and Siberia, as before obſerved, and the other a native of China, inhabitants of humid ſoils, where they arrive to a conſiderable ſtature and magnitude; and from which countries they were many years ſince introduced into the European gardens, as ornamental trees in the pleaſure-ground; being hardy enough to ſucceed in the open air all the year, in any common ſoil and ſituation, and thrive as in their native climate; and are all eaſily raiſed from ſeed, layers, and cuttings, as hereafter directed.

They, in their general growth, aſſume a picturesque ornamental appearance, being finely branched to the very bottom, always fully adorned with leaves, which are univerſally of a very minute ſize, but very cloſely and curiouſly arranged in an imbricated manner, exhibiting a perpetual verdure: on the whole, the trees effect a very diſtinguiſhable variety at all ſeaſons.

And as to their flowering, they flower early in the ſpring; but the flowers being ſmall and apetalous (without petals), they are not ornamental; are univerſally monoecious, or male and female, ſeparated on the ſame tree; conſiſting wholly of ſcaly calixes, containing the fructifications, collected into oblong and conic bunches; the males being in oblong amentums, and the females in cloſe oval cones, which become that ſort of ſeed-veſſel called a cone, furniſhing ripe ſeed in autumn, or towards ſpring.—See CONIFERÆ and CONUS.

The firſt ſort, *Common American Arbor Vitæ*, is the oldeſt reſident in our gardens, very diſtinguiſhable from the other by the dark-green colour of its leaves; which, however, in winter particularly, aſſume a diſagreeable duſky hue.

But the *Chineſe Arbor Vitæ* is both of more regular growth, and its foliage continued always of a fine lively green, ſummer and winter,

ter, and is generally a more beautiful tree than the other.

However, both the ſorts are in high eſtimation, as fine ornamental evergreens, and moſt elegant furniture for adorning the ſhrubbery, and all other garden-plantations, deſigned for variety and ornament; have alſo a fine effect, diſpoſed ſingly in the open ſpaces of graſs ground, in the ſhrubbery or wilderneſs; in all of which ſituations, ſuffering them generally to grow rural, nearly in their own natural way, except reducing with a knife any very ſtraggling or rambling branches occaſionally; which is principally all the culture they require.

But theſe trees may alſo be employed as timber-trees, on the evergreen foreſt-tree plantations. See FOREST TREES.

They are cultivated in all the public nurſery grounds for ſale, and may be tranſplanted in autumn, or almoſt any time in open weather, from October until March or April.

*Method of Propagation, &c.*

The method of propagating both theſe trees, is by ſeed, layers, and cuttings.

By Seed.—Both the ſorts ripen ſeed in England, and are alſo obtained in great plenty from abroad by the ſeedſmen; and which ſhould generally be ſowed ſoon after they are ripe, or as ſoon as they can be obtained in autumn or ſpring; ſowing them in pots or boxes of light earth, covering the ſeeds half an inch deep, and place the pots, &c. in a ſheltered warm ſituation, or under ſhelter of a frame in bad weather; eſpecially if ſowed in autumn; that the ſeeds may be protected from ſevere froſt, and continued forward in their vegetative efforts: and thus they will ſometimes come up in the ſpring; which, however, are frequently apt to remain in the ground till the ſecond year; obſerving when the plants are come up, the pots ſhould be placed in an eaſt border, to have only the morning ſun, but open to the free air, giving frequent but very moderate waterings all ſummer; and in winter remove the pots again to a ſheltered place till ſpring; then may be pricked out in nurſery-rows, or if they are very ſmall and weakly, let them remain in the pots another year, placing them in the ſhade during the ſummer, and in a ſheltered place in winter; and in ſpring following plant them out in the nurſery, in rows a foot or two aſunder, to remain to acquire due ſize and ſtrength, for final tranſplantation.

By Layers.—The young ſhoots only of one or two years growth are the proper parts for laying, which may be performed early in autumn, bending down the branches to the earth; and lay all the young wood on each, either by ſlit, or twiſt-laying, with their tops only appearing a little above ground; ſhortening any that have much longer tops than the others, (ſee LAYING): thus they will moſt of them emit roots in the earth, and be proper plants by autumn following; when, or rather in ſpring after, they ſhould be ſeparated from the ſtools, and planted in nurſery rows, to remain two or three years, or till of due ſize for the ſhrubbery, &c.

By Cuttings.—Autumn is the beſt ſeaſon for planting the cuttings, which muſt be of the young ſhoots, principally all of the ſame years growth; and ſhould be planted in a ſhady border. Taking therefore opportunity of ſhowery weather, if poſſible, and chuſing the moſt robuſt young ſhoots, cut them off with a ſmall part of the old wood, where practicable, and plant them in rows a foot aſunder, cloſing the earth well about them: they will be properly rooted in one year, fit for planting out in wider nurſery-rows.

TILIA.

Lime, or Linden-tree.

Conſiſt of only two ſpecies, both of them very eminent hardy deciduous trees, of formal growth, proper for ornamental and timber plantations, &c. they riſing with large upright trunks a conſiderable height, branching numerouſly all around, into large regular conical heads, adorned with broad heart-ſhaped leaves, and ſmall pentapetalous flowers, in looſe bunches.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX is concave, five-parted, coloured, and deciduous. — COROLLA, five oblong, obtuſe petals, crenated at top.—STAMINA, numerous awl-ſhaped filaments, and ſimple antheræ.—PISTILLUM, a roundiſh germen, ſlender ſtyle, as long as the ſtamina, and a pentagonal obtuſe ſtigma.—PERICARPIUM, a globular, coriaceous, quinquevalvular, quinquelocular capſule, opening at the baſe, containing roundiſh ſeeds ſingly in each loculi or cell; though very com-

commonly there is but one ſeed in the whole, and ſo ſituated that the capſule often appears unilocular, if incautiouſly examined.

There being but two ſpecies, one is a European tree, and the other is of America; each comprehending ſome varieties, and are all very hardy, and of the deciduous tribe.

[1] TILIA *Europea.*

*European or Common Lime Tree.*] Riſes with an upright ſtraight trunk to a great height and magnitude, branching regularly all round into a large conical head; garniſhed with large, broad, heart-ſhaped, acute-pointed, ſerrated leaves, of a light-green colour; and ſmall whitiſh-green flowers in bunches, at the ends of the branches, having all the flowers deſtitute of nectaria.

*Varieties.*] Common green-twigged Lime-tree, having all the young ſhoots of a light-green colour—Red-twigged Lime-tree, having all the ſhoots of a beautiful red colour, appearing very ſingular in winter, when deſtitute of leaves. — Large-leaved — Smaller-leaved —Rough or elm-leaved —Variegated-leaved, &c.

The green and red-twigged varieties are tolerably permanent, ſo that being raiſed from ſeed, the plants of each will be moſtly ſimilar to the parent tree.

This ſpecies grows naturally in England and moſt parts of Europe, and has been long cultivated as an ornamental tree in garden plantations, both to grow rural, and to form hedge-work regularly trained.

[2] TILIA *Americana.*

*American Black Lime Tree.*] Grows with an upright large lofty trunk, branching regularly into a large formal head, having the branches covered with a blackiſh-brown bark; large, broad, heart-ſhaped, acuminated, ſerrated leaves, of a deep-green above, and paler underneath; and ſmall greeniſh flowers in bunches at the ends of the branches, having all the flowers furniſhed with nectaria.

*Varieties* ] Larger-leaved —Smaller-leaved. —Carolinian long-pointed-leaved.

Both the ſpecies, and their reſpective varieties, flower in ſummer; the flowers ſmall, and of inconſiderable appearance, and are ſucceeded by plenty of ripe ſeed in autumn, contained in ſmall coriaceous or leathery capſules; and by the ſeed all the ſorts are eaſily raiſed in beds of common earth.

Theſe noble trees are quick handſome growers, and obtain a great ſtature and ſubſtance of trunk, particularly the Common Lime, which grows ſixty or ſeventy feet high; and there are accounts of ſome that have meaſured ninety feet in height, and more than eight or ten yards circuit in the trunk, with branchy heads proportionably large; but the timber being of a ſoft light texture is unfit for any ſtrong purpoſes; is however excellent for numerous light uſes, in the turnery and carving branches particularly.

But for purpoſes in gardening, the Lime-tree has been long in great eſteem for ornamental purpoſes, in various garden diſtricts, being valued for its quick and fine pictureſque growth and large elegant light-green foliage, that effect a very diſtinguiſhable diverſity; was therefore in great repute formerly to plant for avenues, and arrange on the boundaries of extenſive lawns, and other ſpacious open ſpaces, as well as to diſperſe in parks, &c. both as detached ſingle objects, and in groups, alſo to plant for ſhade; and in all of which ſuffered to grow rural, and diſplay their beautiful conic heads: they were likewiſe uſed for forming ornamental hedge-rows in large gardens, and along near the fronts of houſes by road ſides, &c. and trained regular by clipping them annually once or twice in ſummer; and were alſo often trained in regular cones, pyramids, hemiſpheres, arches, &c. though for the general part they are conſiderably better calculated for rural objects, than for any kind of hedge-work, or other regular training, eſpecially as they generally begin to drop their leaves the earlieſt in autumn of any other tree: I ſhould therefore adviſe all the ſorts of Limes to be employed principally only as rural trees, and diſpoſed at ſufficient diſtances to allow them full ſcope to branch out all around, and exhibit their heads diſtinctly; and in which they will always appear conſiderably the moſt conſpicuouſly ornamental.

Though from the circumſtance of theſe trees ſhedding their leaves early in autumn, which is more peculiar to the large than ſmaller leaved kinds, they are not in ſuch general repute to plant for ornament in gardens as formerly, becauſe in very dry hot ſummers the leaves often begin falling in July or Auguſt,

guſt, and cauſe a continual litter for a long time.

However, for the ſingularity of their handſome growth, and foliage, they highly demand culture both for variety, ornament, and ſhade; and if principally the red-twigged ſort is planted, they will have an agreeable effect, even in winter, when entirely devoid of leaves.

Theſe trees are likewiſe proper to plant as foreſt-trees, as they will ſoon arrive to timber; and the wood being ſoft and tough, is valued for making many ſorts of houſhold utenſils, and for various light purpoſes in carved and turnery works, as before noticed.

For all of whieh purpoſes, theſe trees may be planted almoſt any where, as they will proſper in any common ſoil and expoſure; are raiſed in abundance, in all the nurſeries, for ſale, and may be tranſplanted any time in open weather, from October till March.

*Method of Propagation, &c.*

The propagation of theſe trees is by ſeed, by layers, and by cuttings.

By Seed.—This ripens abundantly in October, which may be beaten down with a long pole, keeping the green-twigged and red-twigged ſorts ſeparate; and may either be ſowed ſoon after, or preſerved in ſand till ſpring; ſowing them in a bed or border of common earth, previouſly digging the ground, and divide it into four-feet wide beds; then draw the earth off the ſurface evenly, about an inch deep, into the alleys; and then ſow the ſeeds thinly, and touch them lightly down into the earth with the back of the ſpade; which done, directly earth them over, the depth juſt mentioned, which finiſhes the work of ſowing.

Being thus ſowed, they will all come up freely in the ſpring; at which time be careful to keep the beds clean from weeds, and give ſome moderate waterings in dry weather, to forward the plants in growth as much as poſſible, fit for planting out in nurſery-rows by autumn following; though if they have ſhot rather weakly, let them ſtand another year: then planted out in rows two feet and a half aſunder, by eighteen inches diſtance in the lines; here to remain three or four years or more to acquire due ſize to tranſplant for the purpoſes intended, trimming off large ſide-branches from the lower part of the ſtem occaſionally, to encourage their aſpiring more expeditiouſly at top, which muſt be always ſuffered to remain entire.

Theſe trees, when raiſed from ſeed, generally in the end aſſume a more handſome and expeditious growth, than ſuch as are raiſed from layers and cuttings.

When they are from about five or ſix to eight or ten feet high, they are of proper ſize for final tranſplantation: though if any are deſigned principally as foreſt-trees for timber, it is adviſeable to tranſplant them finally in their deſtined places, while they are young, and not more than from two or three to five or ſix feet high.

By Layers.—All the ſorts grow freely by this method: and is alſo, or by Cuttings, a very certain method to continue the varieties.—For the purpoſe of furniſhing layers, proper ſtools muſt be prepared (ſee STOOLS), and the young ſhoots of a year or two old, are the proper parts to lay; which ſhould be performed in autumn or winter, by ſlit-laying, ſhortening the tops of each layer within a little of the ground: they will all be well rooted by autumn following, and moſtly fit to plant out in the nurſery in rows, and there managed as the ſeedling Limes juſt above directed.

By Cuttings.—Cuttings of all the ſorts of Limes will grow, though not near ſo readily as layers: however, when cuttings are intended, chuſe the ſtrong young ſhoots of the year, in autumn or ſpring, and plant them in a moiſt good ſoil; or any ſcarce ſorts may be planted ſeveral together in pots, and plunged in a hot-bed; they will more readily ſtrike root.

TOLUIFERA.

Balſam of Tolu Tree.

It is a large tree of South America, retained here in ſtoves by the curious for variety; is adorned with large winged leaves, and bunches of pentapetalous flowers.

Claſs and order, *Decandria·Monogynia.*

*Characters.*] CALIX is monophyllous, bell-ſhaped, and quinquedented at top.—COROLLA, five petals, four of them being linear and equal, but the fifth is twice as large as the others, and nearly heart-ſhaped.—STAMINA, ten very ſhort filaments, having antheræ longer than the calix.—PISTILLUM, an

an oblong germen, very ſhort ſtyle, crowned with an acute ſtigma.—PERICARPIUM and SEMEN, at preſent undeſcribed.

There is but one ſpecies, viz.

TOLUIFERA *Balſamum.*

*Balſam of Tolu Tree.*] Riſes with a ſtrong robuſt trunk, branching numerouſly and ſpreading, thirty or forty feet high, covered with a thick tough brown bark, large pinnated leaves, compoſed of ſeveral pair of oblong oval lobes, terminated by an odd one; and at the axillas ſmall bunches of yellow flowers, having ſmaller petals, and one large.

It grows naturally in the Spaniſh Weſt Indies, and in this country muſt be cultivated in pots, and placed always in the ſtove, and managed as other tree and ſhrub exotics of that department.

A balſam of great virtue is extracted from this tree, and is much uſed in medical compoſitions.

This tree is raiſed from ſeeds obtained from abroad by the ſeedſmen; which ſhould be ſowed as ſoon as they arrive in pots of light earth, and plunged in the bark-bed; and when the plants are come three or four inches high, pot them off ſeparately, giving water, and plunge them again in the bark-bed; and afterwards managed as directed for other woody exotics of the ſtove. See STOVE PLANTS.

TOMENTOSE Plants.

Such as are covered with *Tomentum*, being a ſort of woolly or hoary, downy pubeſcence, which covers the ſurface of many plants, more particularly thoſe that inhabit the neighbourhood of the ſea; and many of which plants having their leaves and branches ſo cloſely covered with this ſubſtance as to give them a hoary white appearance.

TOURNEFORTIA.

*Tournefortia.*

Conſiſts of ſeveral ſhrubby exotics from the hot parts of America, and cultivated here in ſtoves for variety; one of which is a climber, the others erect growers, garniſhed moſtly with oval and lanceolate ſimple leaves, and monopetalous infundibuliforme flowers at the ſides and ends of the branches.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is monophyllous, five-parted, and permanent. — COROLLA is monophyllous, funnel-ſhaped, with a cylindric tube, globular at the baſe, and with a ſpreading brim, cut into five acuminated horizontal ſegments. — STAMINA, five awl-ſhaped filaments in the mouth of the corolla, having acuminated connivent antheræ. —PISTILLUM, a globular germen, ſimple ſtyle, and ſingle ſtigma. — PERICARPIUM, a globoſe berry, having four roundiſh ſeeds.

This genus received the name *Tournefortia* in honour of M. Tournefort, the illuſtrious French Botaniſt.

There are about eight ſpecies in this genus, moſtly of a ſhrubby nature, and perennial in root and top; and the moſt noted ſorts in the Engliſh gardens are the following; all of which being natives of the hot parts of America, require to be continued always in a hot-houſe in this country.

[1] TOURNEFORTIA *Volubilis.*

*Volubilate or Twining Tournefortia.*] Riſes with long, ſlender, woody volubilate ſtalks, twining round any adjacent ſupport, fifteen or twenty feet high; oval, acuminated, ſmooth leaves, on reflexed footſtalks; and ſmall white flowers in looſe ſpikes, at the ſides and ends of the branches.

[2] TOURNEFORTIA *Suffruticoſa.*

*Suffruticoſe or Underſhrubby Tournefortia.*] Riſes with a ſhrubby ſtalk, branching moderately about three or four feet high; oblong, almoſt ſpear-ſhaped, hoary, whitiſh leaves; and ſmall white flowers in bunches, at the ſides and ends of the branches.

[3] TOURNEFORTIA *Serrata.*

*Serrated or Tree Tournefortia.*] Riſes with a ſhrubby, upright, thick ſtem, branching twelve or fourteen feet high, or more; having oval, ſerrated leaves on rough ſpinous foot-ſtalks; and white flowers in recurved ſpikes terminating the branches.

[4] TOURNEFORTIA *fœtidiſſima.*

*Fœtid Tournefortia.*] Riſes with woody ſtalks and branches, eight or ten feet high, or more, having oval, ſpear-ſhaped, hairy leaves; and white flowers terminating the branches in ramoſe, pendulous ſpikes.

[5] TOURNEFORTIA *Cymoſa.*

*Cymoſe Tournefortia.*] Riſes with woody, branching ſtalks, ſix or eight feet high; large, oval, oblongiſh, naked, ſmooth, entire leaves; and white flowers terminating the branches in cymoſe ſpikes.

[6] TOURNEFORTIA *humilis.*

*Dwarf Tournefortia.*] Riſes with ſhrubby, low, ſlender ſtalks, branching moderately two or three feet high, ſpear-ſhaped, cloſe-

ſitting leaves, and white flowers in ſimple or unbranched recurved ſpikes, produced laterally, or along the ſides of the branches.

Theſe plants remain in leaf, moſtly the year round, and flower in ſpring or ſummer, &c. ſucceeded by ſmall ſucculent berries, containing three or four ſeeds.

They being all very tender exotics, that require the continual ſhelter and heat of a ſtove, in this country muſt be cultivated in pots of good earth, and placed in the ſtove accordingly, and treated like other ſhrubby exotics of this collection, as directed under the article STOVE PLANTS.

All the ſorts may be raiſed from ſeeds obtained from abroad, where the plants grow naturally; and it is adviſeable to ſow them as ſoon after their arrival as poſſible, in pots of light mould, and plunged in a bark-bed; giving occaſional ſprinklings of water, and they will probably come up the firſt year; or if they ſhould remain longer in the ground, continue to keep the mould in the pots all the while moderately moiſt; and when the plants are come up, and advanced three or four inches high, prick them out ſingly in ſmall pots, and plunge them in the bark-bed, and continue them conſtantly in the ſtove.

Their propagation may alſo be tried by layers, &c. in pots plunged in the bark-bed.

TRACHELIUM.

Throatwort.

One hardy herbaceous perennial, of the flowery tribe, for the pleaſure-ground, compoſe this genus; riſing half a yard high, with oval leaves, and umbelliferous-like blue flowers at top.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is ſmall, five-parted, and placed above the germen.—COROLLA, one funnel-ſhaped petal, with a long, ſlender, cylindric tube; and divided at the brim into five ſmall concave ſpreading ſegments.—STAMINA, five capillary filaments, the length of the corolla, having ſingle antheræ.—PISTILLUM, a triquetrous, ſubrotundous germen, ſlender ſtyle, and globoſe ſtigma.——PERICARPIUM, a roundiſh, obtuſe, trilobate, trivalvous capſule, of one cell, having numerous ſmall ſeeds.

There is but one ſpecies, viz.

TRACHELIUM *Cæruleum.*

*Blue Trachelium or Throatwort.*] Hath a thick, fleſhy, fibrated, perennial root; upright ſtalks, about half a yard high; garniſhed with oval, ſpear-ſhaped, ſerrated leaves, and terminated by many ſmall fine blue flowers, in a ſort of umbellate cluſters in June and July, ripening ſeeds in September.

It is a native of ſhady places in Italy and the Eaſt, and is cultivated in our gardens to encreaſe the variety; planted in light dry ſoils, where it will abide ſeveral years: alſo, if ſowed in the crevices of old walls, ruins, and rock-work, they will flouriſh, and be of great duration; but when cultivated in rich moiſt ſoils, they are not ſo durable, often proving biennial.

It is propogated by ſeeds ſowed in autumn, ſoon after they are ripe, or early in ſpring, in a bed or border of light earth; the autumn ſowing will probably come up more freely than that of the ſpring. Obſerving when the plants are two or three inches, prick them in nurſery-rows ſix inches aſunder, to remain till autumn; then may be tranſplanted where they are to remain.

TRADESCANTIA.

Virginia Spiderwort, or Flower of a Day.

It is a hardy herbaceous perennial, of the flowery collection, for adorning the pleaſure-garden; riſing with erect annual ſtalks, a moderate height, ornamented with very long narrow leaves, and tripetalous flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, three oval, concave, ſpreading, permanent leaves.—COROLLA, three large, orbicular, plane, ſpreading petals.—STAMINA, ſix ſlender, erect, hairy filaments, having kidney-ſhaped antheræ.—PISTILLUM, an oval, obtuſely-trigonous germen, filiformous ſtyle, crowned with a trigonal obtuſe ſtigma.—PERICARPIUM, an oval, trivalvous, trilocular capſule, covered with the calix, having numerous ſmall ſeeds.

There are three ſpecies, but not more than one in the Engliſh gardens, viz. *Common Virginia Spiderwort*; comprehending ſeveral varieties, all hardy perennials.

TRADESCANTIA *Virginiana.*

*Virginian Tradeſcantia, commonly called Virginia Spiderwort, or Flower of a Day.*] Hath a thick root, furniſhed with many fleſhy fibres, crowned with many narrow leaves near two feet long; amidſt them erect, thick, ſmooth ſtalks, two or three feet high; garniſhed, long, graminous leaves ſingly; and large tripetalous,

ous, blue, and other coloured flowers in the varieties, crowning the ſtalks in cloſe cluſters.

*Varieties are*] Common pale blue-flowered. Deep blue flowered—Purple-flowered—Red-flowered—White-flowered.

They all flower in June; each flower is generally but of one day's duration; hence the name *Flower of a Day*, but the ſame plant continues producing a plentiful ſucceſſion of new flowers every morning, for a month or ſix weeks, ſucceeded by plenty of ripe ſeed in autumn.

This ſpecies, &c. is a native of Virginia, but have been many years in the European gardens as ornamental flowery plants, for the common borders; they may therefore be planted in any of the borders, or other compartments of the pleaſure-ground, on which they will abide by the roots many years, producing new ſtalks annually in ſpring, and flower very ornamentally every ſummer; and will multiply exceedingly both by their roots, and ſcattered or ſelf-ſowed ſeeds; even ſo much as often to over-run the ground, and require trimming in to reduce them within proper bounds.

They are all eaſily propagated by parting the roots in autumn, or early in ſpring; alſo by ſeed ſowed in the ſpring, in any bed or border of common earth, and raked in; and the plants will riſe plentifully, and be fit to prick out in ſummer, to gain ſtrength till autumn, then tranſplanted finally.

## TRAGOPOGON.

Goat's Beard.

Conſiſts of hardy, herbaceous plants, moſtly biennials, the principal of which in the gardens is an eſculent called *Salſafy*, eſteemed for its carrot-ſhaped, eatable root, and by ſome for the tender ſhoots of its young ſtalks in the ſpring, to eat like *aſparagus*; are moſtly tap-rooted plants, with the roots crowned with long narrow leaves, and with upright ſtalks in ſpring, of moderate height, ſurmounted by large compound flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis*.

*Characters.*] CALIX, a compound flower having the general cup ſingle, compoſed of eight ſpear-ſhaped leaves, alternately larger and joined at the baſe.—COROLLA, the general flower is compound, imbricated, and uniform, compoſed of many monopetalous tongue-ſhaped hermaphrodite florets, five-parted at top.—STAMINA five very ſhort filaments, having cylindric antheræ.—PISTILLUM, an oblong germen filiforme ſtyle, crowned with two revolute ſtigmas.—PERICARPIUM, none, the ſeeds, one in each floret are angular, rough, crowned with down, and lodge in the ſwoln connivent calix.

From the circumſtance of the ſeed being covered with a pappus or down as they remain in the cell, reſembling a goat's beard, it obtained the name of *Tragopogon*, or Goat's Beard.

There are ten or twelve ſpecies, but many of which being plants of no eſtimation for uſe, are but little known; and the moſt noted ſorts are, firſt the ſalſafy, an eſculent, having an eatable root and ſtalks, &c. and two others ſorts principally for variety: the firſt two ſorts are biennials and the third a perennial.

[1] TRAGOPOGON *Porrifolium (Biennial)*

*Leek-leaved Tragopogon, commonly called Salſafy.*] Hath a perpendicular, carrot-ſhaped, white, eatable root, a foot or more long, crowned with many long leek-ſhaped entire leaves, cloſely gathered; and when it runs to ſeed, riſes with upright, hollow, ſmooth, whitiſh ſtalks two feet high, terminated with large compound blue flowers, having the peduncles thickeſt above, and the calix longer than the radius.

It flowers in July, and the ſeeds ripen in autumn, then wholly decays.

This plant grows naturally in meadows in ſome parts of England, &c. but is cultivated in gardens in the manner of carrots, for its long carrot-ſhaped root, which attains a moderately large ſize by autumn and winter, when it is boiled for uſe, and ſerved to table in different ways, and is very tender and palatable: alſo the young ſhoots of the flower-ſtalk in ſpring and ſummer, cut while young and tender, when only a few inches high, are dreſſed in the manner of aſparagus, and ſerved up to table with butter, &c.

It being a biennial, riſes from ſeed in the ſpring, and attains perfection in the root in autumn following, remaining good all winter, and in ſpring after ſhoots up ſtalks for flower and ſeed, and the root then becomes ſticky and uſeleſs, and totally periſhes ſoon after the ſeeds are ripe.

[2] TRAGOPOGON *Pratenſe (Biennial.)*

*Meadow Tragopogon, or Greater Yellow Goat's Beard.*] Hath a taper fibrated root, crowned with very long, narrow, acute, entire leaves gathered together; upright ſtalks near a yard high, garniſhed with long narrow leaves ſingly at each joint; and terminated each ſtalk with one large compound yellow flower, having the calix and radius of equal length.

*Variety.*] Smaller Meadow Tragopogon, having much narrower leaves, and ſtalks only a foot high.

Both the varieties flower in June and July, and the ſeeds ripen in September.

They grow naturally in meadows in England and moſt part of Europe; and are ſometimes cultivated in gardens for variety, and the young ſhoots in ſpring are often gathered and dreſſed, as obſerved of the Salſafy, being frequently brought to the London markets by the ſimplers who gather them in the meadows in April and May; or may be raiſed in gardens by ſowing their ſeed in ſpring in rows ſix or eight inches aſunder, and the plants will ſhoot up for uſe in the ſpring following.

[3] TRAGOPOGON *Dalechampii (Perennial.)*

*Dalechamp's Greater Hawkweed, or French Tragopogon.*] Hath the root crowned with many large, oblong, runcinated, deeply indented leaves; low ſtalks only about five or ſix inches high, ſurmounted by one large yellow flower, having a monophyllous calix ſhorter than the corolla, appearing in June or July, and the ſeeds ripen in autumn.

All theſe plants are hardy: the firſt two being biennials, riſing one year from ſeed and the next ſhoot up into ſtalk, producing flowers and ſeed, then wholly decay; and the third is a perennial, durable in root, ſending up ſtalks annually in ſpring, which decay in autumn.

The firſt ſpecies *(Tragopogon Porrifolium)* is the principal ſort for general culture, as an eſculent, and as ſuch merits culture in every kitchen-garden principally for its roots, as before obſerved, chiefly for autumn and winter uſe; they being eaſily raiſed from ſeed in the open quarters, and will arrive to perfection only in autumn, and continue good till they begin to ſhoot in ſpring following.

It is much cultivated in the London kitchen-gardens for market, where it it commonly brought in bunches, in autumn and winter.

The other two ſpecies are retained in ſome gardens for variety, and the ſecond ſort particularly, is alſo ſometimes cultivated for its tender ſhoots in ſpring, as already hinted.

*Method of Propagation, &c.*

The *Salſafy* is raiſed only from ſeed ſowed in ſpring, in March and April, in an open ſituation to remain, ſowing it either broadcaſt and raked in, or in ſhallow drills, eight or nine inches aſunder, ſcattering the ſeeds thinly, and cover them half an each deep; and when the plants are come up two or three inches high, thin and weed them by hand or hoe, leaving them eight or ten inches aſunder, repeating the weeding as may be required during the ſummer, which is all the culture they require; and they will have large roots by September or October. When you may begin taking them up for uſe; and in November, when the leaves begin to decay, a quantity, may be taken up and preſerved in ſand for uſe in time of ſevere froſt, when thoſe in the ground cannot be digged up.

In ſpring, when thoſe remaining in the ground begin to ſhoot, the ſhoots, when a few inches high, may be cut for uſe as before mentioned; which, when quite young and tender, are excellent eating. Suffer, however, always a few plants to run up to ſtalk every ſpring, to produce ſeed for ſowing.

The other two ſorts may be raiſed alſo from ſeed like the *Salſafy*, and the plants, when a little advanced in growth, may be planted out if they are required for variety in any particular part. If the *Tragopogon Pratenſe* is required for its ſhoots, it ſhould remain where ſowed, and thinned to proper diſtances.

But the third ſort may alſo be propagated by parting the roots in autumn or ſpring.

TRAINED TREES.

For walls and eſpaliers.

The appellation of Trained Trees, is to be underſtood principally of young fruit-trees deſigned for walls and eſpaliers, being trained in the nurſery to the intended form, by planting them againſt any kind of walls, pales, reed-hedge, or other cloſe fence, when a year old from the grafting or budding, training

ing them in the manner of wall or eſpalier trees, for two, three, or more years, till they obtain a good ſpread of branches, arrived to a fruitful ſtate, in order that any perſons, being in haſte to have their walls or eſpalier covered at once with bearing trees, it may be effected in one ſeaſon; as the trees thus trained in the nurſery, &c. being tranſplanted in autumn or ſpring to the places intended, they will both cover the wall or eſpalier conſiderably at once, and bear a great deal of fruit the enſuing ſummer, if a favourable fruit ſeaſon.

So that whoſoever may incline to have his walls thus at once furniſhed with bearing trees, without waiting three or four years longer for younger trees attaining a bearing ſtate, may be ſupplied with ſuch at all the public nurſeries, where large quantities are always ready trained for ſale, more particularly peaches, nectarines, and apricots for walls; likewiſe in many places, cherries and plums, &c. alſo apples, pears, and other fruit-trees for eſpaliers; and are very eligible both to furniſh the walls of any new garden, or newly erected walls in old ones, either wholly or in part, to bear ſome fruit till younger trees, planted untrained, come forward and become fruitful, or may be uſed occaſionally to ſupply the place of very old trees that may happen to fail or bear bad fruit; in all of which, the planting of Trained fruitful trees may prove ſo far preferable to quite young untrained and unfruitful ones planted at the ſame time, in that there will be three or four years difference in the time of their bearing, which is very a material object of conſideration; and that, if the Trained Trees are purchaſed in the public nurſery gardens, you are freed from the trouble of firſt training them to the requiſite form, which requires particular attention the two firſt years, the effecting of which, often ruins many young wall and eſpalier trees at firſt ſetting off, when under the hands of ignorant practitioners; and as to the expence of the purchaſe, between Trained bearing Trees of five or ſix ſhillings, and that of one or two years old untrained ones, of a ſhilling or eighteen pence, cannot be any great object to perſons of fortune, or of any tolerable circumſtances in life, at leaſt to furniſh ſome part of the beſt walls, or to plant alternately with young untrained trees.

Therefore in both public and private nurſeries, it is of much importance to have ſome of the beſt ſorts of wall and eſpalier trees always in training for walls, &c. againſt any kind of fence, either walling, paling, or reed-hedges, both dwarf and half-ſtandard wall trees; alſo againſt ranges of ſtakes in the open quarters for eſpaliers, that there may always be ſome well trained ſpreading trees arrived to a fruitful ſtate, to furniſh any place as above occaſionally with immediate bearing trees of ſome conſiderable ſpreading growth.

When, therefore, it is intended to raiſe trained fruit-trees for walls and eſpaliers, a quantity of the beſt young plants of the reſpective ſorts, both dwarf and half ſtandards aforeſaid, of one year old, with the firſt ſhoots from the budding and grafting entire ſhould be tranſplanted in autumn againſt any kind of fence of any aſpect in a free ſituation, not leſs than four or five feet high; either a wall, paling, reed-fence, &c. before hinted, placing them eight or ten feet diſtance, and here to remain for training as below.

The trees being thus planted, then in ſpring following, juſt as they begin to make an effort for ſhooting, they ſhould be headed down, that is the firſt ſhoots from the budding, &c. to be cut down to within three or four eyes or buds of its origin, or place of inſertion in the ſtock, eſpecially thoſe intended for dwarfs, alſo the half-ſtandards, if worked on tall ſtocks; and this heading down both prevents their running up too high with a ſingle naked ſtem, branchleſs below, and cauſes them to throw out lateral ſhoots from the lower part to fill the wall or eſpalier regularly with branches quite from the bottom upward; for being thus cut over low, they will ſoon after puſh forth ſtrong ſhoots from all the remaining lower buds, ſufficient to give the tree its firſt proper formation as a wall tree, &c. which ſhoots when of due length in ſummer, ſhould be trained along to the fence equally to the right and left, in a ſomewhat inclinated poſition at full length till next ſpring, when theſe ſhoots may alſo be cut down to ſix or eight inches length, to force out a further ſupply of more branches near the bottom, for there is nothing like being well furniſhed with

with branches below at firſt ſetting off, to form a good foundation, whereby you will be able to keep every part of the wall from the very bottom to top covered with bearing wood, for no part of a good wall ſhould be loſt.

So that agreeable to theſe hints, continue ſhortening more or leſs the two or three firſt ſprings on the laſt ſummers ſhoots, as you ſhall ſee neceſſary, in order to obtain a proper ſpread of lower branches to give the tree its intended form; though this work of pruning ſhort to obtain laterals may alſo be performed occaſionally in ſummer, in May or early in June on the ſtrong young ſhoots of the year, cutting or pinching them down to a few eyes, and they will thereby throw out lower laterals the ſame ſeaſon, and by that means a year's growth is gained.

According as the ſupply of branches thus gained by the above methods arrive to proper length in ſummer for training in, they ſhould be accordingly all trained along cloſe to the wall, and if any fore-right or back ſhoots come out, rub them all off cloſe; leaving, however, all the well-placed ſide ſhoots in every part, and let the whole, or as many as poſſible, be trained in during this ſeaſon, to have a plenty to chuſe from in the general pruning ſeaſon of winter or ſpring, training them cloſe to the wall, &c. equally to the right and left, as aforeſaid, on each ſide of the tree, in a ſpreading ſomewhat horizontal manner, no where croſſing one another but at parallel diſtances, and moſtly all at full length during the ſummer's growth; thus to remain till the general winter or ſpring pruning.

In the winter pruning we are to obſerve, that if more wood was trained up in ſummer than now appears neceſſary, or that can be trained in with due regularity, ſhould retrench ſuch ſuperfluities; likewiſe any remaining fore-right or back ſhoots and other irregular growths omitted in ſummer, not eligibly ſituated for training in, ſhould alſo be now all pruned out, cutting every thing of the above nature, both ſuperabundancies and irregularities, quite cloſe to their origin; being careful, however, to leave all the regular, well-placed, uſeful ſhoots that can readily trained with due regularity, without crowding or croſſing one another, all of which ſhould alſo be cleared from all lateral or ſide ſhoots, if any; and with reſpect to their being ſhortened more or leſs, or left entire, you will order according to your diſcretion, agreeable to the afore-mentioned hints, and alſo as noticed below, as the different ſorts may require; though if any rambler extend conſiderably beyond all the others, it muſt be reduced, or cut down to ſome lower ſhoot, conſiſtent with the general form and extent of the reſt of the branches; then, after performing theſe regulations, proceed to the training and nailing in the whole cloſe to wall, &c. in exact order, by ranging them equally each way, in a ſpreading fanned manner, all as ſtraight as poſſible, ſomewhat horizontally, no where croſſing the branches, but all ranged parallel as aforeſaid, one above another, four, five, or ſix inches diſtance, according to the ſorts, making the oppoſite branches of each ſide range as equally as poſſible in the ſame poſition.

Thus, after having obtained a regular ſpread of branches, proceeding immediately near the head of the ſtem, ſufficient to effect the proper expanſion requiſite to form a trained wall or eſpalier tree, they muſt then be pruned according to the method peculiar to each reſpective ſort of fruit, as directed in their culture, each under its proper genus. —Some requiring the branches ſhortened annually, others to be trained moſtly always at full length.

For in the general courſe of training and pruning wall trees and eſpaliers, it muſt be obſerved, that ſome ſort of wall trees require almoſt a general ſhortening every year of the annual ſupply of branches, ſuch as peaches, nectarines, and apricots, which always bear their fruit principally on the young year old wood, have that of each year ſhortened in the winter pruning, to force out a ſufficient ſupply of ſucceſſion ſhoots in proper places all over the tree for the future year's bearing: on the other hand, as apples, pears, plums, and cherries do not want an annual renewal of bearing wood, the ſame branches continue bearing from two or three to many years old; ſo that, after undergoing the operation of ſhortening the firſt two years wood, to obtain a ſpread of lower branches to effect the intended form as a wall or eſpalier tree, they are not afterwards, in the general courſe of pruning, to be ſhortened, but generally always trained at full length, except occaſionally

ſionally ſhortening ſome particular young ſhoot to fill a vacancy. See each kind under its reſpective head, alſo the article of PRUNING *Dwarf Trees, Eſpaliers*, &c.

The training of eſpalier trees is effected exactly in the manner as above, only theſe may be alſo trained as they ſtand in the nurſery lines, in the open quarters or borders, &c. by ranging ſome ſtout ſtakes in the ground along one ſide of each tree, not in a continued ſtraight range immediately the way of the row, but thoſe of each tree ranged ſeparate and obliquely, ſomewhat croſs ways the row as it were, that the branches of the different trees may range beſide one another, and thereby have more room to extend the branches both ways, than the common diſtance in the nurſery-lines would admit, if ranged directly the way of the row.

Obſerve that as it may ſometimes happen ſome of the trained trees, both of the wall and eſpalier kinds, in the courſe of training, may aſſume a ſtate of vigorous luxuriant growth, either in general, or in ſome particular parts, producing ſtrong, rampant, rude ſhoots of a very unfruitful-like nature; they in ſuch caſes, ſhould be ordered accordingly in a peculiar manner, till they have exhauſted their redundancy of ſap, or exceſſive luxuriancy, and effect a more moderate ſtate of growth.

That, therefore, where a general luxuriancy prevails, while under the courſe of training or after, it is adviſeable in the work of pruning to uſe the knife with moderation, in regard to thinning and ſhortening, and rather humour the trees ſomewhat, according to their natural tendency, by leaving the ſhoots and branches thicker or cloſer together than the common rule, and to ſuch as are uſually ſhortened, as in peaches, nectarines, &c. they ſhould be ſhortened much leſs in proportion; that by dividing the ſap amongſt a greater number, as well as larger extent of branches, it checks the luxuriancy which would take place in a ſmaller number and leſs extent of growth. For the more wood we cut out of a generally vigorous ſhooting tree, and the more the ſhoots are ſhortened, as often erroneouſly practiſed, the more vigorous will it continue to ſhoot without ever becoming properly fruitful; and if ſevere cutting is repeatedly continued, the tree often exhauſts itſelf ſo greatly by luxuriant ſhooting, that it ſuddenly aſſumes a weak conſumptive ſtate.

But that the natural inclination of very vigorous young trees, being ſomewhat indulged at firſt by training as many branches as can be conveniently laid in, and thoſe that require ſhortening, cut but moderately, or ſome very luxuriant ones hardly at all; which being practiſed two or three years with diſcretion, it will gradually reduce the trees to a moderate growth, and good ſtate of bearing; when they may be ordered in the common way peculiar to the different ſorts.

On the other hand, ſuch trees as are vigorous only in particular ſhoots, may, in ſome caſes, have ſuch ſhoots radically retrenched, and in others reſerved; that if a very vigorous ſhoot runs conſiderably ſtronger than all the reſt, and ſeems to ſupport its vigour at the expence of the others in its neighbourhood, it ſhould be retrenched to the very origin, as early in the ſummer as diſcoverable; in other caſes, if a luxuriant ſhoot ariſe in any vacant ſpace, towards the bottom eſpecially, where a ſupply of more wood is wanted, it may be retained, and pinched or topped down to a few eyes in May or June, it will ſend out ſeveral laterals below, the ſame ſeaſon, and inſtead of one rude luxurious ſhoot, there will be four or five of moderate growth to fill the vacancy, more effectually, and that will much ſooner attain to fruitfulneſs.

Thus far is chiefly all we have to obſerve relative to the ordering of Trained wall and eſpalier Trees in the nurſery, which being in training from three to four or five years, they obtain a handſome ſpread of fruitful branches, fanned in the requiſite regular form for the purpoſes intended; ſo as when planted in the garden, they at once cover a large ſpace of walling, &c. bearing good fruit the following ſummer.

Other particulars reſpecting their culture, after being planted in their deſtined places in the garden, are exhibited under the heads ſeparately of the reſpective ſorts. See alſo DWARF TREES, ESPALIERS, and PRUNING.

Notwithſtanding what we have here advanced reſpecting the planting of Trained Trees for walls, &c. we would alſo obſerve, that

that for any general plantation, unleſs good Trained Trees can be readily obtained, from three or four to five or ſix years old, of a clear free growth, it will be better to plant entire young trees of one or two years old, immediately from the nurſery rows untrained, planting them at once where they are to remain, and they will probably root more effectually, and aſſume a freer growth than ſtunted Trained Trees, managing them as directed for the Trained Trees, to give them the due formation, and afterwards, agreeable to the rules of pruning directed for the different ſorts in their proper places.

But ſome, to have as great a chance as poſſible, plant both young untrained trees to remain, and Trained Trees of a bearing ſtate, dwarfs and half-ſtandards between, ſo as to cover the wall more effectually at once, and furniſh a ſupply of fruit directly, as it were, and until the young ones are trained and arrive to bearing; then as they advance in growth, and if they appear the moſt thriving, the Trained Trees are gradually cut away, leaving the younger, or more thriving trees, to occupy the wall wholly at laſt.

In moſt of the public nurſeries, they raiſe many Trained Trees for ſale, which occupy all their cloſe fences of walls, pales, or reed-hedges, planted near together, and after being in training two, three, four, or more years, till of a good ſpread and become fruitful they are ready for ſale, and fetch a very good price, generally from three to five or ten ſhillings per tree, according to the ſorts, age, and goodneſs of growth; which pays well for the trouble of training, as any ſort of fence of any aſpect, openly expoſed, ſerves for training them to the proper form.

## TREILLAGE,

### Or TRELLIS.

A *Treillage* is ranges of ſtakes and railing on which to train eſpalier trees; alſo occaſionally for wall trees, where the wall does not admit of nailing the branches immediately againſt it; likewiſe for training wall trees in forcing frames, &c. and may be of different degrees of taſte for uſe and ornament, as well as of different dimenſions, from four or five to ſix or ſeven feet high, as noticed below.

For common eſpalier fruit trees in the open ground, a Treillage is abſolutely neceſſary, and may either be formed of common ſtakes or poles, or of regular joinery work.

The cheapeſt, the eaſieſt, and ſooneſt made Treillage for common eſpalier trees, is, that formed with any kind of ſtraight poles or ſtakes of underwood, as cut in the coppices or woods; being cut into proper lengths, of from five to ſix or ſeven feet, may expeditiouſly form a good Treillage, by driving them in the ground in a range a foot diſtance, all of an equal height, and then railed along the top with the ſame kind of poles or rods, to preſerve the whole ſtraight and firm in a regular poſition. See ESPALIER.

Therefore, to form a Treillage of this kind, we muſt provide ſome bundles of ſtraight poles or rods, either of aſh, cheſnut, or of any other firm durable wood; which, if in the country, may be readily obtained in the adjacent woods or coppices, at a moderate expence, and are ſold at many of the timber yards in the vicinity of great towns; chuſing ſuch as are perfectly ſtraight and of ſufficient ſubſtance, i. e. full an inch and half thick, cutting them into ſix or ſeven feet lengths, as before noticed, and having pointed them at one end, drive them with a mallet into the ground in a ſtraight range cloſe along the row of trees, a foot deep at leaſt, and the ſame diſtance in the line; after which ſaw them even at top, all of an equal level from four to five or ſix feet high, then let ſlips of deal or ſtraight poles, be ranged horizontally along the top the whole length, and nailed down to each ſtake, which finiſhes the whole firmly in a ſtraight range, as well as give an air of greater uniformity; and when thus finiſhed, the branches of the eſpalier trees are to be trained and extended along horizontally from ſtake to ſtake, as directed for the different ſorts under their proper heads, and in the article ESPALIER.

To render the above ſort of Treillage ſtill ſtronger, may run two, three, or more ranges of rods, along the back part of the uprights, a foot or eighteen inches aſunder, faſtening them to the upright ſtakes either with pieces of ſtrong wire twiſted two or three times round, or by nailing them.

But where a more elegant and ornamental Treillage is required in any particular diſtrict, it is formed with regularly ſquared poſts and rails of hard timber, neatly plained and framed

framed together; having for this purpoſe deal or oak poſts, uniformly worked two or three inches ſquare; but if the main poſts are of oak, it will be of particular advantage in reſpect to ſtrength and durability, fixing the main poſts in the ground ten or twelve feet aſunder, with ſmaller ones between, ranging the horizontal railing from poſt to poſt in three or more ranges; the firſt being ranged about a foot or eighteen inches from the bottom, one at top, and a third along the middle ſpace, and if thought convenient may range one between each of the intermediate ſpaces; then fix thin ſlips of lath, or the like, upright to the horizontal railing as far as the branches of the trees extend, ten inches or a foot aſunder; and paint the whole white in oil colour, to render it more ornamental and durable; and in training the trees, tie their branches both to the railing of the Treillage, and to the upright laths, according as they extend in length on each ſide.

In either of the above Treillages for an eſpalier, five or ſix feet is generally of ſufficient height, as if much higher, the winds having greater power, will looſen and diſplace them.

Treillages for wall trees is in ſome places neceſſary, where the walls are built with large ſtones with the joints irregular and far aſunder, not affording opportunities for nailing properly in the due regularity required; in which caſe a neat Treillage is eligible, erected all along cloſe to the wall, on which to train and tie the branches in regular order.

This kind of Treillage may alſo be formed with rods or ſtrong laths, erected chequer or lattice faſhion, faſtened and framed together cloſe to the wall with iron hooks and pieces of wire, as below.

That being provided with a due quantity of clean ſtraight rods or poles, or ſquared laths an inch thick, and a quantity of hooked iron holdfaſts, which are previouſly driven into the joints of the wall in rows at regular diſtances, projecting about an inch or inch and half to receive the rods or laths, both horizontally and perpendicularly chequerways nine or ten inches aſunder; fixing the firſt row of holdfaſts towards the top, the ſecond near the bottom, and the third along the middle ſpace; this done, and the rods or laths ready, which, if thought proper, may be ſquared and planed, then proceed to frame the Treillage by firſt fixing the rods horixontally in three rows, in the three ranges of hooks, as above; obſerving, theſe horizontal rods ſhould be previouſly chopped off to nothing at each end, ſo as they may be readily ſpliced to one another to extend them in length as far as required; thus, having fixed up the three firſt rows of horizontal poles, faſten up ſome uprights or ſtandard rods in front of the horizontal ones, five or ſix feet diſtance, then range the remainder of the horizontal laths behind the ſtandards, nine or ten inches aſunder, faſtening them with wire to the uprights, and being all thus placed and fixed, the reſt of the ſtandards are faſtened up in front at the ſame diſtance, and the whole is made faſt with wire twiſted round the hooks and the croſſings or interſection of the rods of the Treillage.

Or a Treillage of the above kind may be formed of ſquared laths, about an inch thick, planed even and ſmooth and neatly framed together by mortiſe and nailing, &c.

When the Treillage in either of theſe methods is finiſhed, it is adviſeable to paint the whole all over with white lead, to render it both more beautiful and durable.

In forcing-frames and ſtoves, where wall trees are intended for forcing, as they are planted both againſt the back wall, and occaſionally againſt the front glaſſes, a Treillage is abſolutely neceſſary, for the trees muſt not be trained cloſe to the wall, &c. therefore, a Treillage ſhould be erected three or four inches from the wall or glaſſes; formed with ſquared poſts and laths, uniformly framed together in the chequer or lattice manner.

TRIBUS.

Tribes of Plants.

As the whole vegetable creation is diſtributed ſyſtematically into claſſes, orders, genera, and ſpecies, &c. according to the ſexual ſyſtem, there are numbers of plants in theſe different artificial arrangements, that although they differ eſſentially in the fructification or ſexual method, yet are nearly allied in their general growth, habit, and appearance; and may, therefore, for the greater facility of diſtinction, agreeable to nature's ſyſtem, be divided into Tribes according to the affinity they bear to one an-

other in their nature of growth, either in general, or particular parts, and their ſenſible qualities, &c.

For example, they may be divided into Tribes according to the following natural orders.

*Herbaceous Tribe.*] All plants of the herbaceous or herb kind, riſing moſtly with leaves immediately from the root, and with ſoft herbaceous ſtalks not becoming woody, but moſtly die at the end of the ſame year they were produced.

*Ligneous or Woody Tribe.*] All trees and ſhrubs having woody durable ſtems and branches.

*Arboraceous Tribe.*] All plants of the tree kind riſing to a lofty ſtature. See ARBOR.

*Fruticoſous or Shrubby Tribe.*] Plants of the ſhrub kind, riſing but a moderate height, and divide low into ſeveral ſtems, &c. branching in a ſomewhat buſhy manner.

*Deciduous Tribe.*] All kind of trees, ſhrubs, and other plants that caſt their leaves in winter.

*Sempervirent or Evergreen Tribe.*] The various trees, ſhrubs, and other plants that retain their green leaves the year round.

*Annual Tribe.*] Annual plants, called annuals, being ſuch as are only of one year's duration. See ANNUAL PLANTS.

*Biennial Tribe.*] Plants of two years duration. See BIENNIAL PLANTS.

*Perennial Tribe.*] Plants that are perennial or of many years duration, and is applicable both to herbs and trees, though more generally applied to herbaceous perennials. See PERENNIS PLANTA.

*Fibrous-rooted Tribe.*] All kind of plants with fibrous roots. See RADIX.

*Bulbous-rooted Tribe.*] Plants with bulbous roots, ſuch as the onion, tulip, lily, &c.

*Tuberous-rooted Tribe.*] Plants with thick, knobbed, fleſhy roots, ſuch as the anemone, potatoe, and Jeruſalem artichoke.

*Succulent Tribe.*] Plants with fleſhy, juicy leaves, as in *ſedum*, *cactus*, *meſembryanthemum*, *aloe*, *agave*, &c. See SUCCULENTIÆ.

*Pinnated Tribe.*] All ſorts of trees and other plants that have pinnated or winged leaves.

*Enſataceous or Sword-leaved Tribe.*] Plants with ſword-ſhaped leaves, as in *iris*, *gladiolus*, &c.

*Spathaceous Tribe.*] Plants producing their flowers out of a ſpatha or ſheath, as in *narciſſus*, *galanthus*, and *amaryllis*, &c. See SPATHACEA.

*Liliaceous Tribe.*] Plants producing flowers with ſix petals or diſtinct ſegments, reſembling a lily in form, ſuch as the tulip, &c. See LILIACEÆ.

*Papilionaceous Tribe.*] Plants that have papilionaceous or butterfly-ſhaped flowers, ſuch as all the pea and bean kind, and all the other leguminous plants. See PAPILIONACEÆ.

*Leguminous Tribe.*] Plants having that kind of ſeed-veſſel called a legumen, legum, or pod, as in all the pea, bean, kidney-bean, and other papilioneous-flowered plants.

*Campanaceous Tribe.*] Plants with campanulated or bell-ſhaped flowers, as the *campanula* and *convolvulus*, &c.

*Rotaceous Tribe.*] Plants with rotated or wheel-ſhaped flowers, as in *lyſimachia*, *anagallis*, &c.

*Umbelliferous Tribe.*] Plants producing their flowers in an umbel, as in *angelica*, *anethum*, *paſtinaca*, &c. See UMBELLA.

*Verticillate Tribe.*] Plants producing their flowers in a verticillus or whorl, as in *thymus*, *hyſſopus*, *meliſſa*, *origanum*, *ſclaria*, *mentha*, &c. See VERTICILLATÆ.

*Aggregate Tribe.*] Plants producing their flowers in an aggregate, conſiſting of numerous ſmall flowers or florets, each having its proper calix, and all collected into a cloſe aggregate head, as in *ſcabioſa*, *ſtatice*, *globularia*, &c. See AGGREGATE.

*Compoſitus or Compound Tribe*] Plants with compound flowers, conſiſting of numerous florets contained in one common calix, as in ſun-flower, marigold, aſter, &c. See COMPOSITUS FLOS.

*Amentaceous Tribe.*] Plants producing their flowers in amentums or catkins, as in *populus*, *corylus*, *fagus*, *betula*, &e. See AMENTACEOUS FLOWERS.

*Coniferous Tribe.*] All trees and plants bearing that kind of fruit called a cone. See CONIFERÆ and CONUS.

*Baccaceous Tribe.*] All berry-bearing plants.

*Pomaceous Tribe.*] Plants bearing fruit of the apple kind *(pomum)* as in the *pyrus malus*, *pyrus communis*, *pyrus cydonia*, *amygdalus*, *prunus*, *meſpilus*, *punica*, &c.

*Nuciferous Tribe.*] All nut-bearing plants.

*Oleraceous Tribe.*] Eſculent or eatable plants for the table, and other domeſtic uſes.

*Lurid*

*Lurid Tribe.*] Plants of an ominous appearance, hurtful or noxious; as in *atropa*, *datura*, *nicotiana*, *ſolanum*, *capſicum*, *digitalis*, &c.

*Graminous Tribe.*] Graſſy plants; all plants of the graſs and corn kind.

TRIFOLIUM.

Trefoil, or clover, &c.

The plants are herbaceous annuals, biennials and perennials, rarely cultivated in gardens, but of great eſtimation for paſture lands as fodder for cattle; have all fibrous roots crowned moſtly with tufts of ſmall trifoliate, or three-lobed leaves, and ſend up ſtalks in ſummer a foot or two high, and ſome trailing; adorned alſo with trifoliate leaves, and terminated by ſmall papilionaceous flowers in heads or ſpikes.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous tubular five-parted at top, and permanent.—COROLLA, is papilionaceous, having the vexillum reflexed and with ſhort wings and carina — STAMINA, ten diadelphous filaments, having ſimple antheræ.—PISTILLUM, a nearly oval germen awl-ſhaped ſtyle, crowned by a ſimple ſtigma.—PERICARPIUM, a ſhort univalvular pod, containing a few roundiſh ſeeds.

There are near fifty different ſpecies of *Trifolium*, but many of them being plants, of but little value or eſtimation, either for garden or field culture, are rarely cultivated; ſo that the moſt material ſorts are the following two ſpecies.

[1] TRIFOLIUM *Pratenſe.*

*Meadow Trefoil or Red Dutch Clover.*] Riſes with many ſlender branchy ſtalks near two feet high; having trifoliate leaves of three large folioles, membraneous ſtipulæ placed oppoſite round the foot-ſtalks; and monopetalous reddiſh-purple flowers in hairy ſpikes or tufts, at the ends of the branches, in May and June.

*Varieties.*] Purple-leaved—White flowered, and ſome others.

[2] TRIFOLIUM *repens.*

*Creeping White Dutch Clover.*] Hath trailing, creeping ſtalks, ſpreading and rooting at the joints; trifoliate leaves; and white flowers growing in umbellate heads at the ſides and ends of the branches, ſucceeded by pods having four ſeeds.

Both theſe ſpecies of Trefoil or Clover, are found in abundance in our meadow and paſture grounds, and are the only ſorts of this genus for general culture in laying down graſs-land, and are raiſed from ſeed ſowed in May or autumn as directed below.

They are perennials, though the firſt often proves only biennial, by ſometimes dying away after it has ripened ſeeds, but the ſecond ſort is always biennial, growing very cloſe and thick, is more valuable than the other for continued paſture.

However the firſt ſort, or red Dutch Clover, grows abundantly, producing wonderful great crops, and is moſt excellent for laying down land to cut for fodder for all kinds of cattle for two years; for on account of its biennial nature above-mentioned, it does not always ſucceed well much longer; though if it is cloſe eaten in ſummer, or mowed down when coming into flower, it ſhoots out below from the root again, and often proves ſomewhat perennial; but conſidered as a biennial, the farmers commonly ſow it with barley in the ſpring, and when the barley comes off in July or Auguſt, the Clover ſpreads and covers the ground, and ſhoots up ſtrong early next ſummer, either to feed off, or mow for hay; and after ſtanding two years, they generally plough the ground again for corn.

But the ſecond ſort, creeping white Dutch Clover, is more valuable than the other for laying down ground, deſigned to be continued long in paſture, its ſeeds being mixed and ſowed with graſs; and as it grows low and cloſe, with trailing abiding ſhoots, ſpreading every way and rooting at the joints, it ſoon overſpreads the ground, and forms a cloſe thick ſward, of many years duration; and affords the moſt excellent feed for all ſorts of cattle.

Both the ſorts are propagated by ſeed, which is ſold by all the ſeedſmen, generally at ſo much per pound; and from ſix to eight or ten pounds is the allowance for an acre.

The ſeaſon for ſowing it, is principally in the ſpring in March and April, or may be ſowed in autumn, any time in Auguſt, or early part of September; is generally mixed with graſs ſeeds, and ſowed broad caſt and lightly harrowed in with a ſhort-teethed

harrow, and in a day or two after, when the ſurface is dry, roll the ground with a horſe wooden roller, to break the clods and ſmooth the ſurface, but the farmers commonly ſow theſe ſeeds with corn, ſuch as barley, &c. for the ſake of making the moſt of the land, and when the corn comes off the Clover and graſs take their growth, though it will prove much more proſperous and forward if ſowed alone, as the corn, when very thick and high, is apt to retard its growth, and ſometimes ſpoil the crop.

TRITICUM.

Wheat.

This remarkable genus conſiſts of hardy herbaceous plants, moſtly annuals or biennials, valuable for producing that moſt excellently uſeful grain called Wheat; are fibrous rooted plants, riſing with graſſy leaves and upright, tall, ſlender ſtalks, terminated by cloſe ſpikes of chaffy flowers, ſucceeding to ſpikes or ears of corn.

Claſs and order, *Triandria Digynia.*

*Characters.*] CALIX, is a bivalvous chaff, having the valves oval, obtuſe and concave, containing ſometimes many florets.— COROLLA, is ſmall bivalvous florets, as large as the calix, having the outer valve bellied and pointed and the inner one plane.—STAMINA, three hair-like filaments, with oblong forked antheræ.—PISTILLUM, a turbinated germen, two capillary reflexed ſtyles, and plumoſe ſtigmas—PERICARPIUM none; one oval-oblong ſeed for each floret, obtuſe at both ends, and wrapped up in the corolla.

There are many different ſpecies of Wheat, the principal ſorts of which are,

[1] TRITICUM *hybernum.*

*Winter or Common Brown Wheat.*] Hath long ſpikes or ears, having four florets in each calix; and the grains of corn ranged in four rows, in an imbricated manner, with ſmooth, ventricoſe, or bellied chaff, almoſt without beards or awns.

This is commonly ſowed in autumn to ſtand the winter; hence called Winter Wheat.

[2] TRITICUM *æſtivum.*

*Summer or Spring Wheat.*] Hath ſpikes with bellied ſmooth calixes, ranged imbricatim, containing four flowers each, and are furniſhed with awns.

This ſort is ſometimes ſowed in ſpring, as it ripens much earlier in ſummer than the other.

[3] TRITICUM *turgidum.*

*Turgid or Duck-bill Wheat.*] Hath large thick turgid ſpikes with bellied hairy calixes, placed imbricatim, having four florets each, and moſtly furniſhed with awns.

[4] TRITICUM *Polonicum.*

*Polonium or Poland Wheat.*] Hath long ſpikes with naked calixes, having two flowers in each, which are long, and furniſhed with awns or beards.

[5] TRITICUM *quadratum.*

*Four-rowed Conical Wheat.*] Having oblong conical ſpikes, armed with long awns or beards.

Theſe are the principal ſpecies of Wheat generally cultivated, and which comprehend ſeveral varieties, differing ſomewhat in the form of their ſpikes and chaff, &c.

But the ſort proper to cultivate for general uſe, is principally the Winter or common brown Wheat without awns; though all the ſorts are alſo occaſionally cultivated in different parts of the country.

All the ſorts of Wheat may be conſidered both as annuals and biennials; for conſidered as annuals, that being ſowed in the ſpring, they ſhoot up to ſtalk, and produce ripe corn the ſame year in autumn, and wholly periſh ſoon after; and as biennial, that being ſowed in autumn as practiſed for the Winter, and Turgid Wheat, &c. the plants riſe the ſame year, ſtand all the winter, and ſhoot to ſtalk and corn in ſpring and ſummer following, and totally die in autumn, as ſoon as the corn is ripe.

Theſe plants having ſpreading fibrous roots, they generally riſe with ſeveral ſtalks, eſpecially if they have room to ſpread, in which caſe they often produce from five or ſix to eight or ten ſtalks, each ſtalk terminated by a ſpike of corn.

They ſhoot up into ſtalk in May, and flower in June, conſiſting of numerous chaffy florets, collected into long cloſe ſpikes at top of the ſtalks, each chaff or calix containing two, three, four, or more chaffy florets, and moſtly placed imbricatim or over one another like ſcales of fiſh, all along the ſpike, ſome entirely without awns, and ſome with, either leſs or more, as in their deſcription, and ſucceed to ripe heads of corn in July or Auguſt, fit to reap and ſtack up for uſe.

As to the propagation of Wheat, it is effected by ſeed ſowed every year, principally in autumn, from Auguſt or September until

November

November, the ground being previouſly well ploughed for the reception of the ſeed, allowing generally two or three buſhels to an acre; which for the general part is ſowed broad-caſt and harrowed in, and in ſome places in drills drawn by the drill plough, &c. a foot diſtance or more, which method of ſowing requires a conſiderably leſs quantity of ſeed than the broad-caſt ſowing, and affords opportunity of horſe-hoeing between the rows to kill weeds and ſtir the ſurface of the earth about the plants; which, as having more room generally grow ſtronger and produce a greater number of ſtalks on each root, than ſuch as grow cloſe in the broad-caſt; though as the broad-caſt ſowing is the moſt ready and expeditious method, it is the moſt generally practiſed for ſowing Wheat, and almoſt all ſorts of corn.

TRIUMFETTA.

*Triumfetta.*

Compriſes two tender exotics, a ſhrubby, and an herbaceous plant, natives of the Indies, and retained here in ſtoves for variety; riſe with erect ſtalks ſeveral feet high, adorned with roundiſh leaves, and pentapetalous flowers in ſpikes at the ends and ſides of the branches, ſucceeded by round bur-like capſules.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX, five ſpear-ſhaped deciduous leaves.—COROLLA, five linear, concave, retroflexed petals.—STAMINA, twelve or fifteen awl-ſhaped riſing filaments, having ſingle antheræ.—PISTILLUM, a roundiſh germen, a ſingle ſtyle the length of the ſtam na, having a bifid acute ſtigma. — PERICARPIUM, a globular prickly capſule, having four cells, each containing two ſeeds.

There are two ſpecies, one a woody perennial, the other an annual, but the former of which is the ſort commonly kept in the Engliſh gardens.

TRIUMFETTA *Lappula.*

*Lappula, or Jamaica Triumfetta.*] Riſes with an upright woody ſtem, dividing upward into a few branches, and grows five or ſix feet high; roundiſh trilobed-leaves, emarginated at the baſe, and numerous ſmall yellow flowers, collected in ſpikes at the ends of the branches.

It muſt be always kept in pots, and plunged in the bark-bed or the ſtove, and managed like other ligneous plants in the ſtove collection.

It is propagated by ſeed obtained from abroad, ſowing it in a hot-bed, or in pots, and plunged in the bark-bed, where the plants will ſoon come up; which, when advanced one, two, or three inches high, ſhould be planted in pots ſeparately, and placed in the bark-bed of the ſtove to remain.

TROLLIUS, Globe Ranunculus.

Globe Flower or Locker Gowlans.

They are hardy, herbaceous, flowery perennials for adorning the flower garden; have fibrous roots, crowned with divided leaves and upright annual ſtalks, two feet high, terminated at top with large polypetalous globular flowers.

Claſs and order, *Polyandria Polygynia.*

*Characters.*] CALIX, none.—COROLLA, about fourteen nearly oval connivent petals, and nine narrow, incurved, umbilicated nectariums.—STAMINA, numerous briſtly filaments, having erect antheræ.—PISTILLUM, numerous germina, ſitting cloſe in a columnar form; no ſtyle, but the germen crowned by pointed ſtigmas.—PERICARPIUM, numerous capſules collected in a head, each having one ſeed.

There are only two ſpecies, both perennials, one an European plant, the other an Aſiatic exotic, but both hardy enough to grow in the open ground all the year.

[1] TROLLIUS *Europeus.*

*European Globe Flower, or Locker Gowlans.*] Hath a black, fibrous, perennial root; ſending up many roundiſh leaves, deeply cut into five ſegments, which are alſo divided and notched; upright ſtalks, about two feet high, dividing into branches upwards; each terminated by one large globular yellow flower, having the petals connivent or converging together, and the nectaria the length of the ſtamina.

[2] TROLLIUS *Aſiaticus.*

*Aſiatic Globe Flower.*] Hath a fibrous perennial root, crowned with large divided leaves, upright ſtalks, near two feet high, dividing into branches, terminated each with one large ſaffron-coloured flower with ſpreading petals, and the nectaria the length of the corolla.

Both theſe plants flower in May very ornamentally, each flower being large and elegant, compoſed of many large concave petals; which in the firſt ſort particularly, converge

verge or turn inward in a revolute manner, ſo as to give the flower a perfect globular form; hence is called Globe Flower, and is ſucceeded by plenty of ripe ſeed in autumn; but the flower of the ſecond ſpecies *Trollius Aſiaticus*, is not connivent but ſpread out and exhibit the nectariums and ſtamina; alſo of a fine ſaffron-colour, effecting an elegant ſingularity, and is ſometimes ſucceeded by ripe ſeeds in our gardens, and by ſeed both the ſorts may be raiſed, and they alſo multiply exceedingly by the root, which will be of many years duration, and produce flowers annually.

As therefore thoſe plants, when in flower, effect a ſingular variety, they merit a place in every curious collection in the compartments of the pleaſure-ground; and the ſeaſon for planting them is in autumn when the leaves decay, or early in ſpring.

Remarking, however, that as they are natives of moiſt, ſhady, cool places, they are generally the moſt proſperous planted in ſuch ſituations in gardens.

Their propagation is accompliſhed by parting the roots, and occaſionally by ſeed.

By parting the Roots.—Autumn, when the leaves decay, is the beſt ſeaſon to perform it, or early in the ſpring, taking up the roots, and divide them into ſeveral parts, not, however, into two ſmall ſlips, and plant them either where they are to remain, or in nurſery rows for a year; they will grow freely and moſtly flower the ſummer following.

By Seed.—Sow it in a ſomewhat ſhady border in autumn or ſpring in ſhallow drills, and cover it almoſt half an inch deep, they will readily grow and be fit to plant out in ſummer, or towards autumn, in rows half a foot aſunder, to remain ſix or eight weeks to acquire ſtrength, then planted out finally.

TROPÆOLUM.

Indian Graſs, commonly called *Naſturtium.*

Conſiſts of herbaceous annuals or perennials, of very long, trailing, and climbing growth, in eſtimation for effecting variety in the pleaſure-ground in ſummer, but require protection of a green-houſe in winter; grow with long ſtalks trailing many feet along the ground, or upon ſupport, adorned with large roundiſh peltated or ſhield-ſhaped leaves, and numerous pentapetalous flowers all along the branches, of ſingular ſtructure.

Claſs and order, *Octandria Monogynia.*

*Characters.*] CALIX is monophyllous, horned, coloured, divided into five, acute, erect, ſpreading ſegments, and is deciduous.—COROLLA, five roundiſh petals, inſerted into the diviſions of the calix; the two upper ones ſit cloſe, and the three lower ones have oblong ciliated tails or claws.—STAMINA, eight ſhort, declinated, unequal filaments, having erect, oblong, riſing, quadrilocular antheræ.—PISTILLUM, a roundiſh, trilobate, ſtreaked germen, ſingle erect ſtyle, and a trifid, acute ſtigma.—PERICARPIUM, three roundiſh, convex, furrowed berries, having three roundiſh, furrowed ſeeds, with one ſide gibbous, the other angular.

There are only three ſpecies, two of which are common in the Engliſh gardens; conſidered principally as annuals, but if ſheltered in winter in a green-houſe, will prove of a perennial nature, exemplified in the double *Naſturtium.*

The ſpecies are,

1 TROPÆOLUM *minus.*

*Minor or leaſt Naſturtium.*] Hath long trailing ſtalks, branching and extending ſeveral feet along the ground, or upon any ſupport; large, roundiſh, or orbicular peltated entire leaves, of a grey colour, having the foot-ſtalk inſerted into the center; and numerous yellow flowers at the axillas, all along the ſide of the ſtalk and branches; all the flowers having acuminated petals.

*Varieties.*] Pale yellow-flowered—Orange-coloured.

2 TROPÆOLUM *majus.*

*Major or greater Naſturtium.*] Hath large, very long, trailing ſtalks, branching and extending ten or fifteen feet or more along the ground, or on ſupport, garniſhed with large, orbicular, peltated leaves, almoſt indented into five lobes; having the foot-ſtalks inſerted into the center; and numerous large yellow flowers at the axillas, all along the ſides of the branches; with all the flowers having obtuſe petals.

*Varieties*] Pale yellow-flowered. — Orange-coloured flowers. — Double-flowered, commonly called Double Naſturtium, retained generally as a green-houſe plant.

Both theſe ſpecies of *Tropæolum*, and reſpective varieties, flower in great profuſion from June until autumn, or till killed by the froſt; and the flowers are of ſingular form, being, in their ſingle or characteriſtic ſtate, compoſed of five unequal petals, the two upper

upper ones large, and the three lower ones narrow, with long tails joining together, and extended conſiderably behind; but in the Double Naſturtium the petals are multiplied exceedingly, even to the excluſion of the generative organs, and conſequently no ſeed is produced; but in all the common ſingle varieties the flowers are ſucceeded by great plenty of ſeed, contained in roundiſh, berry-like, green fruit. See the *Characters*.

Theſe plants are all hardy enough to grow any where in the full ground all ſummer, until October or November, but are unable to endure the cold in winter.

They are generally deemed annuals, as they riſe from ſeed in the ſpring, attain full perfection, flower, and produce ſeed the ſame year, and totally periſh the enſuing winter, if in the full ground; but if any are raiſed in pots, and removed under ſhelter of a green-houſe, or good garden-frame, under glaſſes, at the approach of cold weather, they will ſtand over the winter, and may thus be preſerved ſeveral years, as practiſed for the double *Naſturtium*; and, like that ſort, be propagated alſo by cuttings, planted in the ſpring; though as they are eaſily raiſed in great abundance from ſeed ſowed in ſpring or ſummer in the full ground, the preſerving them over the winter is rarely attended to, except to a plant or two, by way of variety: and always for the double ſort in particular, as not producing ſeed, nor if it did, would there be any certainty of continuing its doubleneſs by that method, is therefore propagated always by cuttings, and kept in pots to have ſhelter in winter.

All the ſorts are cultivated in gardens, both as flowery plants, and for œconomical uſes in their flowers and ſeed, for ſallads and pickles; conſidered however as ornamental flowery plants, the common ſingle ſorts are diſperſed in patches about the borders, and other compartments, and generally trained up to ſome ſupport, or to run on any kind of treillage, railing, or the ſides of arbors, or to be trained againſt fences, &c. ſowing the ſeeds at once where they are to remain; ſome in patches, as aforeſaid, two or three ſeeds together, near an inch deep; placing tall branchy ſticks, when they come up, for the plants to run upon: others may be ſowed in ſhallow drills, the ſame depth, along any kind of fences, as above, on which alſo to train the plants: and in ſome particular open compartments may ſow ſome to remain as trailers, and extend along the ground, agreeable to their natural growth.—In all of which methods, the ſeeds being ſown any time in ſpring or ſummer, they will grow freely, and the plants will ſoon ſhoot out ſtalks and branches numerouſly, when they ſhould be trained in the order intended, as hinted above.

But as to the double *Naſturtium*, this is always conſidered as a green-houſe plant; for although it will live in the open air all ſummer, like the other varieties, it cannot bear the winter's cold, ſo muſt be kept always in pots of light earth, and placed among the green-houſe exotics, placing ſticks for their ſupport: thus they will remain ever-green, and effect variety very agreeably, and produce abundance of flowers all ſummer and autumn; alſo often moderately in winter; obſerving during the winter to allow them but very little water, as too much moiſture would rot them at this ſeaſon of the year.

Conſidered as œconomical plants, or eſculents, before noticed, the common ſingle varieties of both the ſpecies are often cultivated for their flowers and fruit, the former for ſallads, and the latter to pickle; for the flowers being of a warm, agreeable reliſh, are by many greatly eſteemed to mix in ſallads, alſo as garniſh to ſallads, when ſent to table in form; and are likewiſe in great eſtimation for garniſhing diſhes of meat, &c. and as to the fruit, this, when young and green, is an excellent pickle, and for which purpoſe particularly the plants are cultivated in many gardens.

When therefore it is intended to cultivate theſe plants as eſculents, for the flowers and fruit, they may be ſowed in the kitchen-garden in April or May, either in patches or in ſhallow drills, an inch deep; and when the plants come up, place branchy ſticks for their ſupport, and they will thus ſupply you with abundance of flowers and fruit from June or July until October.

*Method of Propagation, &c.*

The method of propagation is by ſeed annually, for all the common ſingle varieties, ſowing it in ſpring, the end of March, or in April or May, in patches or drills, in the places where the plants are to remain, as above obſerved.

But

But the double *Naſturtium* not producing ſeed, and being only a variety, is propagated by cuttings of its branches, and by which it will always retain its double property: planting the cuttings any time from April until July, in pots of light earth, and placed in the ſhade, giving moderate waterings occaſionally; or thoſe planted early may be plunged in any moderate hot-bed, to facilitate their rooting more effectually.

TROWEL. A Garden Trowel.

A Garden Trowel, made of iron, in a hollow or ſcooped form, is a handy uſeful implement in taking up and tranſplanting numerous ſorts of ſmall plants and bulbous roots; planting in pots; ſowing in patches, &c. and various other ſimilar light works in gardens.

This kind of Trowel being of iron, from twelve to ſix inches long in the plate, and half as broad, hollowed like a ſcoop, and fixed on a ſhort handle, to hold with one hand, proves a moſt convenient handy tool in a variety of garden operations; for being hollowed ſemicircularly, it is remarkably handy in removing many ſorts of ſmall plants with a ball or lump of earth whole about their roots, ſo as not to feel their removal; lifting bulbous flower roots after the flowering is paſt in ſummer; planting bulbs in patches or little clumps about the borders; as alſo for digging ſmall patches in the borders for ſowing hardy annual flower-ſeeds; likewiſe for filling mould into ſmall pots in planting any ſort of plants therein; ſtirring the ſurface of the mould in pots, and freſh earthing them when neceſſary. It is alſo moſt ufeful for filling in earth about plants in hot-beds, and under frames, and any ſmall compartments where a ſpade cannot be readily introduced. And ſuch a Trowel is likewiſe very convenient for pointing over or ſtirring the ground between rows of ſmall cloſe-placed plants in beds or borders, &c. and for many other purpoſes occaſionally.

But to ſuit the ſeveral purpoſes more effectually, it would be proper to be accommodated with two different ſizes of ſcooped Garden Trowels, viz.

A common larger one for general uſe, being about twelve inches long in the plate, and ſix broad, narrowing gradually to the bottom.

A ſmaller one for particular purpoſes about ſix or eight inches in the plate, and four broad, narrowing pretty conſiderably towards the bottom, to introduce between ſmall plants.

They may be had of different ſizes at moſt of the ironmongers where they ſell ſpades; or any common ſmith may eaſily make them.

TRUNCUS, Trunk, the main Stem of trees and plants.

The Trunk riſes immediately from the root, and may be deemed the ſtock or main body of the vegetable, as it multiplies into branches, buds, leaves, flowers, and fruit. See CAULIS.

The Trunk or Stem is of ſeven ſorts, viz.

*Caulis.*—The moſt common ſpecies of Stem, both of trees and herbs, or ſuch as produces and ſupports the leaves, flowers, and fruit. See CAULIS.

*Scapus.*—Is an herbaceous, naked Stem, that elevates the fructification only, and not the leaves, as in *Narciſſus*, *hyacinthus*, &c.

*Culmus.*—A ſtraw or haulm, being the Trunk or Stalk peculiar to the graſſes and corn, bearing both leaves and flowers; and ſometimes flowers and no leaves.

*Frons.*—The Trunk of the palms and fern tribe, being a compound Stem, formed of a branch and leaf blended together, and frequently alſo the flower and fruit.

*Stipes.*—The Trunk or Stem of the muſhroom, and other *fungi*.

*Pedunculus.*—A peduncle, or flowering-ſtalk, riſing ſometimes from the root, but moſtly from the branches, elevating the flowers and fruit, but not the leaves. See PEDUNCULUS.

*Petiolus.*—A leaf-ſtalk bears the leaves only, and not the flowers. See PETIOLUS.

TUBEROUS ROOTS, ſuch as conſiſt of one or more ſwelled or knobbed tubers, of a ſolid fleſhy ſubſtance, as in the turnep, anemone, potatoe, &c.

TUBUS, a Tube or Pipe, being the lower, narrow, hollow part, of a monopetalous flower.

TULIPA. Tulip.

This moſt noted genus furniſhes a grand collection of bulbous-rooted flowery perennials of admirable beauty and elegance, conſiſting of about two or three ſpecies, one of which in particular produces moſt beautiful and ſuperb flowers, and comprehends a prodigious family of varieties, even to the amount of thouſands, having all large bulbous roots, crowned with long, broad, ſpear-

ſhaped leaves, and erect flower-ſtalk, from half a foot to a yard high, terminated with large liliaceous, bell-ſhaped flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none.—COROLLA is bell-ſhaped, and compoſed of ſix large, oblong, oval, concave, erect petals.—STAMINA, ſix ſhortiſh, awl-ſhaped filaments, having oblong, quadrangular, erect antheræ.—PISTILLUM, a large, oblong, trigonal germen, without a ſtyle, and crowned by a triangular three-lobed ſtigma.—PERICARPIUM, a trigonous, trivalved, trilocular capſule, containing many plane or flat ſemicircular ſeeds, reſting upon one another in a double order.

There are three ſpecies, two of which only are known in the Engliſh gardens; and one of theſe in particular (the *firſt ſort*) is famous for the extraordinary beauty of its large noble flowers, moſt elegantly ſtriped and ſtained with a vaſt diverſity of rich colours, in a thouſand various forms; conſtituting ſo many different varieties, all very great ornaments to our gardens in April and May.

1 TULIPA *Geſneriana.*

*Geſner's Turky Tulip of Cappadocia, or common Garden Tulip.*] Hath a large, oblong, tunicated, ſolid, bulbous root, covered with a brown ſkin, ſending up long, oval, ſpear-ſhaped leaves; an upright, round ſtalk, from half a foot to a yard high, garniſhed with a few leaves, and its top crowned with a large bell-ſhaped, erect, hexapetalous flower, of almoſt all colours and variegations in the different varieties.

*Varieties.*] Early Dwarf Tulip *(Præcocea)*, riſing with ſhort ſtalks, from five or ſix inches, to ten or twelve high, with ſmalliſh flowers——Tall late-flowering or common Tulip *(Serotina)* riſing from about half a yard to two or three feet high, with large well-formed flowers—Double Tulip, riſing a foot or two high, or more, having large double flowers—Whole-blowing, or ſelf-coloured Tulip, being all of one original colour, either purples, reds, violets, greys, copper-colours, yellows, &c. which gradually break into numerous variegations.—Variegated Tulip, compriſing innumerable varieties, in reſpect to the different colourings, variegations, and ſtripes.

Each of the above principal varieties of this ſpecies, comprehends numerous intermediate ones, in reſpect to the colours and variegations of the flower; each however is originally all of one colour, eſpecially ſeedings, which, when arrived to a flowering ſtate, each ſeparate flower is either wholly red, purple, violet, grey, brown, black, or yellow, &c. without any variegations or ſtripes, conſiſting of ſelf-coloured flowers, with white bottoms; ſelf-coloured flowers with yellow bottoms; and ſome alſo with blue, purple, and blackiſh bottoms; all of which, whilſt they retain this original ſame colour, are, in the floriſts' language, called *Whole Blowers* or *Breeders*, becauſe each flower is wholly of one ſelf-colour; and the roots being planted a year or two in prepared ſoils, to breed, or diſpoſe them gradually to produce flowers that break from the original ſelf-colour into variegations and ſtripes, in various different forms; and are then called *Breakers*, each different variegation conſtituting a diſtinct variety; conſiſting of flowers with—white bottoms, broken with brown ſtripes, with blue ſtripes, violet ſtripes, roſe ſtripes, red ſtripes, &c. ſeparated by ſtreaks of white and other colours, variouſly diſpoſed.—Yellow bottoms, broken with different reds, crimſons, and golden-yellow flakes, and various other colours.—Some alſo with blackiſh purple bottoms, &c. broken with ſtripes of dark colour, yellow, and tincts of red; ſo that in theſe ſorts of Breakers, or variegated Tulips, with white and yellow bottoms particularly, there are alſo, white and red-ſtriped flowers—white and purple-ſtriped—white and violet-ſtriped—white and roſe-ſtriped—white and brown-ſtriped—violet and white-flaked—red and white-flaked—red and yellow-flaked——brown, yellow, and red-flaked, and numerous other intermediate variegations and ſtripes, variouſly diſpoſed in an endleſs diverſity.

Thus the Breakers or variegated Tulips are diverſified with an infinity of colours in innumerable different ways, forming ſo many different varieties, the principal of which are by the floriſts diſtinguiſhed by pompous names, either of ſome great perſonages, eminent floriſts, places of their original growth, &c. but as vaſt numbers of new varieties are annually obtained from ſeedlings, in ſo many different places, diſtinguiſhed by various new names, and old ones rejected; and often the ſame flower, with a different name

impoſed by different floriſts, it would be impoſſible to give any correct liſt here of the names of ſuch numerous varieties, ſo often changing every where.

[2] TULIPA *Sylveſtris.*

*Wild European Tulip.*] Hath an oblong bulbous root, ſending up long, narrow, ſpear-ſhaped leaves; and a ſlender ſtalk, ſupporting at top a ſmall yellow flower, nodding on one ſide, having acute petals.

Both theſe ſpecies of *Tulipa* are hardy perennials, durable in root, or at leaſt, although the old bulb decays annually, it perpetuates its ſpecies by off-ſets, and is annual in leaf and ſtalk; which riſing from the bulb early in the ſpring, arrives to a flowering ſtate in April and May, each plant having only one flower, ſupported on the top of the naked ſtalk, without any calix or cup, and conſiſts of ſix large petals, three within and three without, moſtly in an erect poſition; the whole together forming a ſort of large cup, either bell, or egg-ſhaped; though the Double Tulip have the petals multiplied in an indeterminate number. All the varieties are ſucceeded by plenty of ripe ſeed in July and Auguſt, contained in an oblong capſule of three cells, having the ſeeds placed on each other in double rows, (ſee the *Characters*); and by the ſeeds numerous new varieties may be raiſed; which however will not attain a flowering ſtate till they are ſeven or eight years old, and after that will require two or three years or more to break into variegations, when the approved varieties may be marked, and encreaſed by off-ſets of the root, as directed in their *Propagation.*

It is remarkable, that although the Tulip may be ſaid to be a perennial plant, yet, after the bulb arrives to a flowering ſtate, the ſame individual old root or bulb does not always remain to flower again, but gradually waſtes away, as may be obſerved by its relics at the lifting ſeaſon; but, however, previous to its diſſolution, it affords from its ſides a ſupply of ſuckers or off-ſet young bulbs, to perpetuate the ſpecies; and one of which being large, and ſimilar to the parent bulb, is capable of flowering equally ſtrong next year; ſo that at the end of many years, what is often ſtill ſuppoſed to be the ſame individual bulb, is in reality another in every reſpect.

Remark, that of the two ſpecies of Tulip, the firſt ſort, *Tulipa Geſneriana*, or common Garden Tulip, and its vaſt train of varieties, is the ſort ſo generally cultivated for the ornament of our gardens, and ſo much admired by all for its great variety and beautiful appearance, grows freely in the open ground in any common ſoil of a garden, and proves a very great decoration to the beds and borders of the pleaſure-ground, for ſix weeks or two months in ſpring, by different plantings of early and late ſorts; planting the principal part in autumn, and the reſt towards Chriſtmas, and in January or February; the autumn plantings will come earlieſt into bloom, and flower the ſtrongeſt; and the others will ſucceed them in flowering; obſerving that in ſummer, when the flowering is paſt, and the leaves and ſtalks aſſume a ſtate of decay, the bulbs of the choiceſt varieties are generally taken up, the off-ſets ſeparated, and the whole cleaned from filth; then put up in the dry till October or November, and then planted again for the future year's bloom.

As to the ſecond ſpecies, *Tulipa Sylveſtris*, it having but little beauty, in compariſon with the others, is not near ſo generally known or cultivated; though it was formerly in eſtimation, before the Turkey Tulip was ſo general; and is ſtill to be ſeen remaining in many old gardens; and it alſo deſerves culture in modern ones, both for its early flowering, and to encreaſe the variety, in concert with the common Tulip, and other ſpring flowers, in the open borders.

However, all the ſorts of Tulips being very hardy perennials, they will proſper in any common ſoil of a garden, and are admirable fine ornaments for adorning the borders and flower-beds; the roots being planted in autumn, the more ordinary ſorts in rows or patches, along the front of borders, and the fine varieties in beds by themſelves, as hinted in the articles *General Obſervation* and *Their general Culture.*

*Arrangement and Merit of the different Varieties.*

As we formerly obſerved, the firſt ſpecies, Common Tulip, &c. is the floriſt's delight, and merits univerſal eſtimation for its vaſt profuſion of beautiful varieties, which may be divided into two principal claſſes, viz.

1. Early or Dwarf Spring Tulips (*Præcocea.*)

2. Late flowering tall Tulips (*Serotina.*)

Remark

Remark however, of theſe two claſſes, that although the firſt claſs (early Tulips) is in great eſtimation for its early bloom and lively colours, yet the ſecond claſs is in ſtill higher repute for its ſtately growth and great diverſity of rich colours, and profuſion of varieties; and is the moſt univerſally cultivated.—See each claſs as below.

*Early Tulips.*——The early Tulips are among floriſts diſtinguiſhed by the appellation of *Præcoces* (early), becauſe they flower early in the ſpring, a month or more before the others; are much ſhorter ſtalked, and the flowers ſmaller; but are in great reputation for their early bloom, and their gay lively colours, both of ſelf-colours, and broken into flaked variegations; ſuch as reds, crimſon, ſcarlet, carnation, violets, purples, yellow, &c. with flowers of each, edged and flaked with red, yellow and white, in many diverſities.

That the bulbs of theſe early ſorts being planted in any good, light, rich earth, in a warm ſituation, in the end of September, or any time in October or November, in yard-wide beds, in rows, ſix or eight inches aſunder, and three or four inches deep, they will riſe early in the ſpring, and arrive to flower in March, continuing till the late Tulips come into flower.

Though as the early dwarf ſorts are well adapted for forcing, they may ſtill be blowed earlier, by either planting the roots in pots or boxes in autumn or winter, and place them in a ſtove, or a hot-bed, whereby they may be forwarded into bloom in January and February, or earlier; and a ſucceſſion continued till the natural ground-bloom arrives; or may place a quantity of bulbs upon phial-glaſſes of water, in autumn or winter, one bulb in each glaſs, and place them either in any warm, light room of a houſe, near the windows, or in a green-houſe or ſtove, by which they will alſo flower very agreeably in winter, and early in ſpring; they being the beſt adapted ſorts of Tulips for all theſe methods of blowing.

They are ſold by the ſeedſmen and nurſerymen in great collections of different ſorts, by names, chiefly Dutch or French, ſuch as the *Duc van Toll*, &c. as may be ſeen in moſt of the flower-catalogues.

*Late-flowering Common Tulips.* —— This claſs is denominated late-flowering, and by the floriſts called *Serotines*, becauſe they blow later in the ſpring, a month or more, than the *Præcoces*, i. e. not coming into flower before the end of April, May, and June; are all of tall growth, ſupporting large flowers, and furniſh an almoſt endleſs variety in the vaſt diverſity of colours, after they break from whole-blowers into variegations and ſtripes, exceeding all others of the Tulip kind in beauty and elegance of flower.

Tulips are alſo ſubdivided into other claſſes, ſuch as Whole Blowers, and broken Tulips.

*Whole Blowers or Breeders.*—Theſe are ſeedling Tulips, having flowers wholly of one colour; they being raiſed from ſeed to a ſtate of flowering, the flowers remain two, three, or more years of one ſelf-colour, before they break into variegations; which are alſo divided into claſſes, according to the Dutch floriſts called,—1. *Bizzares*; being generally almoſt of a brown copper colour, having at the bottom a ſmall round ſpot, either yellowiſh, or black mixed with a little yellow, which when broken into different colours, become *Bizzares* with yellow bottoms.—2. *Violettes*, being either all of a purple-violet, pale-violet, grideline, cherry-crimſon, or red; having the ſpot at bottom, either a clear white, or blackiſh-grey mixed with a little white; and their production when broken into different colours become Tulips with white bottoms, called by the Dutch, *Bybloemens*.

*Broken or Variegated Tulips.*—Such that are broken from the ſelf original colour of the whole-blower or breeding Tulips, into variegations and ſtripes of different colours; obſerving, they generally break into different variegations according to that of the former ſelf-colour; generally however, either wholly expelling the original ſelf-colour of the breeder, or leave but very little remains thereof, which is a deſirable requiſite in theſe kind of flowers among profeſſed floriſts; and when thus broken or variegated with different colours, they exhibit themſelves variouſly mixed, ſtriped, flaked, feathered, marbled, ſpotted, edged, &c. a thouſand different ways in an admirable manner; and are by the floriſts divided into the following claſſes, called by the Dutch

*Baguette primo.*—Tulips with white bottoms, ſtriped with brown, &c.

*Baguette rigaut.*—Tulips with a white bottom, broken with dark-brown ſtripes, &c.

*Bybloemens.*—Tulips with a white bottom, ſtriped with violet and blackiſh brown, &c. —White bottom Tulips ſtriped with roſe-colour, vermilion, and ruby.

*Bizzares.*—Yellow bottom Tulips, ſtriped with various colours.

Among floriſts the principal properties requiſite in the above claſſes of Tulips to conſtitute a fine flower, are—The ſtem muſt be tall, eſpecially of the *Serotines*, from half a yard, to two or three feet high, or more, being proportionably thick and ſtrong; the flower large, compoſed of ſix petals, as in the characteriſtic ſtate, theſe being broad, thick, rounded at top, and ſtand firmly erect without turning much inward or outward, but ſo as to cup well, and give the flower a regular form. The colours and ſtripes of the flower muſt be bright, ariſing unmixed, regularly and diſtinct from the bottom with but little or none of the original ſelf-colour remaining.

The colours in greateſt eſtimation in the broken tulips, are the blacks, golden yellows, purple violets, roſe, and vermilion, each of which being variegated various ways; and ſuch as are ſtriped with three different colours diſtinct and unmixed, with ſtrong regular ſtreaks, with but little or no tinge of the breeder, may be called the moſt perfect Tulips.

Though it is rare to meet with a Tulip poſſeſſing all the properties, yet have ſufficient perfection to render them of high eſtimation as fine flowers.

As to the manner of obtaining this wonderful variety of colours in Tulips, it is often accompliſhed principally by nature alone, which however is ſometimes aſſiſted and forwarded by ſome ſimple operations of art, ſuch as, that in the firſt place, when the ſeedlings bulbs of the whole-blower or breeder are arrived to full ſize, and have flowered once, to tranſplant them into beds of any poor dry barren ſoil, in order that by a defect of nutriment in the earth, the natural luxuriance of the plant may be checked, and cauſe a weakneſs in their general growth, whereby they generally in this weakened or infirm ſtate, gradually change and break out into variegations, ſome the firſt year, others not till the ſecond or third; and according as they are thus broke, they ſhould be planted in beds of good earth, as hereafter hinted.

Another method to aſſiſt nature in effecting the marvellous work of breaking the breeding Tulips into diverſified colours, is to make as great a change as poſſible in the ſoil; if they were this year in a light poor ſoil, plant them the next in a rich garden mould, and another year in a compoſt of different earths and dung; or tranſplant them from one part of the garden to another, or into different gardens, &c. or from one country to another; all of which contributes in aſſiſting nature in producing this deſirable diverſity of colours and variegations.

The double Tulip is alſo a variety of the common Tulip, is very beautiful, though not in ſuch eſtimation among the floriſts as the common ſingle variegated ſorts; not poſſeſſing ſuch a profuſion of variegations in the colours and regularity of ſtripes; they however exhibit an elegantly ornamental appearance, as they riſe with an upright, talliſh, firm ſtem, crowned with a very large double flower compoſed of numerous petals, multiplied in ſeveral ſeries one within another like a double peony, but far more beautiful in their diverſity of colours, variegations, and ſtripes of white and red, or yellow and red, &c. ſo that they highly deſerve culture both in beds alone, near the other ſorts, to increaſe their variety; alſo to plant in patches about the borders, in aſſemblage with the late variegated Tulips, as they blow nearly about the ſame time, i. e. April and May.

### *General Obſervations.*

As we before hinted, all the varieties of Tulips ſucceed in the open ground, in beds or borders of any common garden-earth planted as hereafter directed.

The roots are ſold in full collection, conſiſting of numerous varieties, at moſt of the nurſeries and ſeedſmen's, who both propagate them themſelves by off-ſets and ſeed, and import vaſt quantities annually from Holland; the Dutch being famous for raiſing the grandeſt collections of the fineſt Tulips, and other bulbous flowers, in the greateſt perfection, for the ſupply of almoſt all the other European gardens; diſtinguiſhing every variety

variety in their vaſt collections by ſome pompous name or other, as before obſerved, arranged in regular catalogues; charging prices in proportion to their eſtimation, which formerly was ſo great, among the Hollanders themſelves in particular, that there are accounts of a ſingle root being ſold for from two thouſand to five thouſand five hundred guilders; however they are now more plentiful, and are ſold at from five or ten ſhillings to ſo many pounds, per hundred, and ſometimes conſiderably more for very ſcarce capital ſorts: and the moſt eligible ſeaſon to buy in a collection, is early in autumn; i. e. any time from Auguſt or September, till November.

And as to the ſeaſon for planting them is in autumn; about October and November is the moſt proper period for putting in the main collection, to blow in April and May following; but, in order to have a later bloom by way of ſucceſſion, ſome may be planted in December, January, or February; though they will not flower near ſo ſtrong as thoſe planted in autumn or the early part of winter.

But the early Tulips ſhould generally be allowed a warm, ſheltered, ſunny ſituation, on account of their early riſing and flowering in the ſpring, whilſt the weather remains cold and pinching; generally alſo always kept ſeparate and planted in beds by themſelves, not promiſcuouſly with the late tall Tulips; for as their ſtature and time of flowering are different, they would not diſtinguiſh themſelves to proper advantage: may alſo diſtribute ſome in the fronts of warm borders in patches, in concert with anemonies, ranunculuſſes, &c.

However, as to the late Tulips, or *Serotines*, they may be planted in any of the common beds or borders, as they will be in no danger from any inclemency of weather.

But the fine or more valuable ſorts in general, both early and late kinds, are commonly depoſited all together in beds by themſelves; the early and late kinds in ſeparate beds, in rows eight or nine inches aſunder, that they may exhibit a grand blow together, and that they may be readily defended if neceſſary, eſpecially when in bloom, from heavy rains, and the ſcorching ſun, occaſionally.

Though as to the inferior ſorts, they may be diſtributed about the common borders in patches, three or four roots in each, in which they will have a fine effect when in bloom.

*Their General Culture.*

Having given the foregoing preparatory hints, will now proceed to the general culture of the plants.

Firſt, with regard to ſoil and ſituation, it has already been ſuggeſted, that all the varieties of Tulips will grow very freely in any common light mould that lies dry in winter, generally preferring an open ſunny expoſure; though nothing can hurt a Tulip but too wet ſoils, ſo that if the ſituation of the ground in any place proves naturally low and wet, the beds muſt be raiſed a few inches above the common level; though the floriſts often prepare ſtudied compoſts to form beds for their fineſt Tulips (ſee COMPOSTS.) However, to ſave trouble and expence, they will be found to ſucceed in any good garden-earth; only obſerving it is not adviſeable to plant the fine ſorts particularly, more than one or two years together in the ſame bed or earth, without making ſome alteration in the ſoil, either wholly or in part, by removing ſome of the old, and adding an equal portion of freſh earth, either from any of the kitchen-garden quarters, or any compoſt heap, or elſewhere, that is good: and wheel away the old earth to ſupply the place of the new; and thus by renewing the ſoil leſs or more, the Tulips may be expected always to blow ſtronger and fairer in proportion; though this is only adviſed for the fineſt ſorts that are planted together in beds; thoſe intended to decorate the open borders, may be planted any where as the ſoil happens, and they will alſo flower very well.

But to proceed in preparing the beds for the choicer ſorts, as formerly obſerved: let the ground be well digged one or two ſpades deep, and form the beds three or four feet wide, moderately high in the middle, and of a rounding form, with wide alleys between bed and bed; and rake the ſurface of the bed even, ready for the reception of the bulbs.

Then, when the beds are thus prepared, proceed in a dry day to plant the bulbs or Tulip roots, in rows, either by bedding-in, drilling, or dibble-planting (ſee PLANTING), marking out lines lengthways the bed, eight

or nine inches aſunder, in which plant the roots ſingly, four or five inches deep, and ſix diſtant in the lines; and when they are all thus planted, rake the ſurface of each bed ſmooth.

Thoſe you intend for the open borders, may either be planted in a line a foot from the edge, or diſpoſed in patches or little clumps, three or four roots together, in a patch of ſix or eight inches diameter, ſome patches forward, others more backward to effect a greater diverſity.

After the Tulips are planted, they require no care till the following ſpring and ſummer; as being in no danger from the rigours of winter, they do not want covering; and in ſpring, no more is required than keeping them clean from weeds; except you chuſe to protect the buds of the choicer kinds in the beds, by covering them in cold nights with mats, ſupported on hoop arches, though it is not abſolutely neceſſary; or when the bedded Tulips are come into flower, if you would protect them to preſerve their beauty as long as poſſible, it may be effected by ſhading them from the noon-day ſun, heavy rains, and tempeſtuous winds, with a ſhade or awning of canvaſs or mats erected acroſs the beds, which by ſome is made high like a tent, to walk under and view the flowers at pleaſure: though we would alſo obſerve that theſe flowers will blow in great perfection without all this care of covering; only that by protecting ſome of the fineſt ſorts growing in beds, the blow may be prolonged a week or fortnight longer in full beauty, than thoſe that are fully expoſed; being careful to remove all covering as ſoon as ever the flowers begin to fade, to admit the free air, rains, &c. for the benefit of the roots.

When however the flowering is paſt, or as ſoon as ever the flowers are faded, it is proper to cut off the head or ſeed-veſſel of the fine varieties particularly, that it may not rob the root of any nouriſhment, which will thereby encreaſe more conſiderably in ſize and ſtrength.

Though when intended to ſave ſeed for ſowing, ſome heads of the ſtouteſt plants muſt be left to ripen.

The next care is in June, when the leaves and flower-ſtem are decayed and withered, determining that the roots have ceaſed growing, and draw no nouriſhment from the earth; at which period of reſt is the time for lifting or taking them up out of the earth, in order both to ſeparate the encreaſed off-ſets, and to reſerve them out of ground till autumn, that they may have ſome reſpite from growth, as well as to be planted in freſh-prepared beds to promote the merit of the future year's bloom; and which work of lifting theſe bulbs ſhould be practiſed annually at the above period to all the choicer kinds, in the beds, and alſo to the more inferior ſorts in the borders, &c. at leaſt every other year, if they appear to have encreaſed by off-ſets conſiderably. See BULBUS.

Therefore, at the above period, of the decay of the ſtem and leaves, taking the opportunity of dry weather, proceed with a garden trowel to dig them up carefully one and one, with all the off-ſets to each; ſpreading them in a dry, airy, ſhady place, here remaining two or three weeks out of the ſun and wet; but expoſed to the free air, they will gradually dry and harden; then detach the off-ſets and all adhering earth, and the outer decayed ſkins or huſks that are the relicks of the old bulb; after which expoſe them again in the ſame place to dry, and harden effectually; then put them up ſafe in the dry, in boxes, the large bulbs and the off-ſets ſeparately, to remain till the time of planting them again arrives.

Obſerving, the flowering bulbs are to be planted as has been already adviſed, and the off-ſets in ſeparate beds, by way of a nurſery, to remain to acquire due ſize and ſtrength to flower, then managed as the other flowering bulbs. See BULBUS.

Thus far concludes the principal general culture of the great family of Tulips; we ſhall now next exhibit the general method of propagation.

*Method of Propagation.*

All the ſorts of Tulips are propagated abundantly by off-ſets of the root annually, and are alſo raiſed from ſeed to gain new varieties.

By Off-ſets.—The old bulbs encreaſe faſt by off-ſets bulbs from their ſides, and which ſhould generally be ſeparated annually, eſpecially thoſe of the fine Tulips; and the ſeaſon for this is in June, when the flower is paſt, and the leaves and flower ſtems begin

to wither; then take up the roots wholly, and ſeparate the ſmall encreaſed off-ſets from the larger bulb, planting the off-ſets in nurſery beds, in drills ſix inches aſunder, and three deep, to remain a year or two to grow to a flowering ſtate; managing the flowering bulbs as already directed.

Thus by off-ſets may all the ſorts of Tulips be propagated in great abundance, and by off-ſets every approved ſort continued always the ſame, ſo that being in poſſeſſion of any new or approved varieties, may with one ſoon encreaſe the ſtock by off-ſets annually, and will generally produce flowers ſimilar to their reſpective parent bulb. See Bubus.

By Seed.—This is a moſt tedious undertaking, as the Tulip, from the time of ſowing the ſeed, is ſeven or eight years before it produces flowers; and after all, they at firſt appear only ſelf-colours, before explained, often requiring two, three, or more years longer before they break into different colours or variegations, ſo that the tedioufneſs of raiſing ſeedling Tulips to a flowering ſtate, often deters many from the undertaking. It is however, the method by which all the fine varieties of Tulips were firſt obtained, and new varieties are ſtill annually gained, as many perſons ſow ſome every year, in expectation that after the firſt ſix or ſeven years a new ſhew of flowers will be produced, and out of which many new varieties will annually diſcover themſelves in each parcel; and it is by this proceſs the Dutch are famous for furniſhing ſuch an infinity of fine varieties, ſupplying almoſt all other countries in Europe.

Therefore, for the ſatisfaction of thoſe who may incline to embark in this tedious undertaking, we will exhibit the method of ſowing and rearing the ſeedlings to a flowering ſtate.

The ſeed for this purpoſe ſhould be ſaved from ſome ſtrong-blowing plants, that are always fully expoſed to the free air, ſuffering them to ſtand till the heads or ſeed-pods and ſeed are duly ripened; then gathered in a dry day, and laid by upon a ſhelf, &c. till September, the ſeaſon for ſowing them; which may be performed either in a bed of any good light mould, in the full ground, expoſed only to the morning ſun; or in boxes or large pots of light earth, and placed in a ſimilar ſituation: obſerving, if in beds, to ſow the ſeed in ſhallow drills, and cover it near an inch deep; and if in boxes or pots, ſow it on the ſurface, and cover it the ſame depth; they will come up the following ſpring with fine graſs like leaves; at which time be careful to keep the young plants very clean from weeds; likewiſe give frequent moderate waterings in dry weather, continuing it occaſionally as long as they retain their green leaves in a growing ſtate, and not after; and when the leaves decay, clear the ſurface careſully from weeds and moſs, if any, and directly ſift a little freſh mou'd over the ſurface half an inch deep, which is all that is required till next year; when the plants will riſe with much ſtronger leaves, in proportion to the encreaſed growth and ſtrength of the bulbs; which, when their leaves again decay in ſummer, ſhould be taken up and planted in nurſery beds, in drills two inches deep, and the ſame diſtance in the lines, with the rows four or five inches aſunder; here to remain and take their growth for two years, keeping the beds clean from weeds, and ſift ſome freſh earth over the ſurface every autumn, half an inch deep; then, in the ſecond ſummer, when their leaves decay, the roots being by that time conſiderably improved in growth, ſhould be again taken up, and planted in a freſh prepared bed, in drills three or four inches aſunder, in which to remain two years longer; then at the decay of the leaf, ſhould be again tranſplanted into freſh beds, in rows as before; where let them remain to blow, afterwards ordered as the other flowering bulbs of Tulips, in the manner already ſhewn.

Obſerve however, when they are in full flower, to examine them with attention, in order to mark ſuch of them as diſcover the beſt properties, that they may be ſeparated from the others at the proper lifting ſeaſon, and replanted in beds by themſelves for breeders; removing them annually at the proper ſeaſon into different beds of oppoſite or contrary ſoils, as before ſuggeſted; ſuch as one year in poor hungry earth, the next in a much richer mould; and ſo continue till they break into variegations and ſtripes of different colours.

Thus each year as the flowers break into colours, mark them in order to be taken up, and

and ranked with the other improved varieties.

TURNERA.

Turnera.

Comprehends tender exotics of ſomewhat ligneous growth, natives of the hot parts of America, and retained here in ſtoves for variety; riſing with erect ſtalks, dividing into branches; adorned with oval and ſpear-ſhaped leaves, and pentapetalous flowers at the ſides of the branches.

Claſs and order, *Pentrandria Trigynia.*

*Characters.*] CALIX, is monophyllous, bell-ſhaped, tubulous, divided into five ſegments, and is permanent.—COROLLA, five heart-ſhaped, pointed, plane-ſpreading petals, with narrow claws, inſerted into the tube of the calix —STAMINA, five awl-ſhaped ſhort filaments, having acuminated erect antheræ.—PISTILLUM, a conical, germen, three ſlender ſtyles, and multifid capillary ſtigmas. —PERICARPIUM, an oval, trivalvous, unilocular capſule, containing many oblong obtuſe ſeeds.

1 TURNERA *Ulmifolia.*

*Elm-leaved Shrubby Turnera.*] Riſes with ligneous, ſhrubby-like, branchy ſtalks, ſix or eight feet high; garniſhed with oval, ſpear-ſhaped, rough leaves, having two glands at the baſe; and yellow flowers ſitting cloſe to the foot-ſtalks of the leaves towards the upper part of the branches.

*Variety.*] Narrow Elm-leaved Turnera.—(*Anguſtifolia*).

This ſpecies and variety are ſomewhat of a biennial nature, as that after being raiſed from ſeed, &c. they are frequently apt to go off the ſecond or third year; though they alſo often prove of longer duration. Obſerving, that as they are tender exotics from South America, they muſt be kept always in pots, and placed conſtantly in the ſtove.

They begin flowering in June, continuing in ſucceſſion very ornamentally all ſummer and autumn, ſucceeded by ripe ſeeds in September.

Both the varieties are eaſily raiſed from ſeed, ſowed in the ſpring in pots, and plunged in the bark bed, or any other hot-bed, under glaſſes; and when the plants are come up, two, or three inches high, plant them ſeparately in ſmall pots, which plunge alſo in the ſtove bark-bed, and order them as other exotics of ſimilar temperature.

TUSSILAGO.

Colt's-Foot.

It conſiſts of low, hardy, herbaceous, creeping-rooted perennials, for variety and medical uſes, remarkable for producing their flowers before their leaves, riſing with low erect ſtalks only a few inches high; roundiſh, heart-ſhaped, and oval leaves cloſe to the ground, and the ſtalks terminated by ſmall compound flowers, ſome radiated, and ſome without a radius.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, a compound flower, having a cylindrical cup compoſed of fifteen or twenty linear, ſpear-ſhaped, equal ſquama or ſcales.—COROLLA, a variouſly compound flower; being either all hermaphrodite florets, or hermaphodites only in the diſc, funnel-ſhaped, and four or five-parted at the brim; and the female florets, where any, are narrow, tongue-ſhaped, and entire. —STAMINA, in the hermaphrodites, five very ſhort hair-like filaments, having cylindric antheræ.—PISTILLUM, a ſhort, germen, thread-ſhaped ſtyle, longer than the ſtamina, which in the females is bifid.—PERICARPIUM, none; a ſingle ſeed in each floret, which is oblong, compreſſed, and crowned with a hairy down.

There are about nine ſpecies of *Tuſſilago*, the moſt material of which are the following, conſiſting of the common *Tuſſilago*, and five other ſpecies.

1 TUSSILAGO *Farfara.*

*Farfara, Common Tuſſilago, or Colt's-foot.*]—Hath fibrated, creeping, white, perennial roots; ſending up ſingle, thickiſh, imbricated ſtalks, five or ſix inches high; that are uniflorous, or each crowned with only one largiſh, pale-yellow, radiated flower, appearing in March and April before the leaves; and when the flower is paſt, the leaves ariſe, being large, roundiſh, nearly heart-ſhaped, angulated, indented, and hoary.

This ſpecies inhabits moiſt ſituations every where in Britain, and moſt parts of Europe in great plenty, creeping and multiplying exceedingly by the roots; and is not much cultivated in gardens.

It

It, however, is worth culture in the herbaceous collection, both to effect variety among the ſpring flowers, in patches in the borders, where it will exhibit an agreeable ſingularity; and may alſo be cultivated as a medicinal plant, its leaves being often uſed in decoctions, and as a principal ingredient in the Britiſh Herb Tobacco.

It is one of the *filius ante pater* tribe, i. e. ſon before the father; becauſe the flowers always ariſe before the leaves.

[2] TUSSILAGO *Alpina.*

*Alpine or Mountain Colt's-Foot.*] Hath a creeping perennial root, ſending up an almoſt naked ſtalk, only three or four inches high, which is uniflorous or crowned with only one purple flower, in March and April, and almoſt round, or orbicular heart-ſhaped, crenated leaves, downy underneath.

*Variety.*] Round hoary-leaved.

[3] TUSSILAGO *Anandria.*

*Anandria, or Siberian Colt's Foot.*] Hath a creeping, perennial root ſending up erect ſomewhat ſcaly ſtalks, three or four inches high, crown each with one purpliſh flower early in the ſpring; and oval lyre-ſhaped leaves cloſe to the ground.

[4] TUSSILAGO *Petaſites.*

*Petaſites, Tuſſilago Major, or Common Butter Bur.*] Hath a thick, fleſhy, creeping, perennial root; ſending up thick hollow ſtacks; ſix inches high, crowned with ſeveral purpliſh flowers, collected in an oval thyrſe or ſpike, having all the florets floſcular hermaphrodites, and large roundiſh heart-ſhaped leaves, from one to two feet broad; grows wild in moiſt meadows, &c. in England and other parts of Europe, and is a medicinal plant.

[5] TUSSILAGO *Hybrida.*

*Hybridian German Tuſſilago, Greater Colt's Foot, or Long-ſtalked Butter Bur.*] Hath a creeping perennial root; ſending up ſtalks ſix or eight inches high, crowned with an oblong thyrſe or ſpike of flowers, having many naked, floſcular, female florets; and large leaves ariſing after the flower is paſt.

[6] TUSSILAGO *alba.*

*White Alpine Tuſſilago, or ſmaller Butter Bur.*] Hath creeping perennial roots; ſlender ſtalks, three inches high; crowned with a flat thyrſe or ſpike of white flowers; and largiſh leaves, ariſing after the flowers are paſt.

All theſe ſpecies of *Tuſſilago* are very hardy perennials, of great duration in root, but annual in ſtalk and leaves, and moſtly all poſſeſs the ſingularity of producing their flowers before the leaves; the flowers riſing immediately from the root on low tender foot-ſtalks, having in ſome ſorts only one flower at top; in others, ſeveral collected in a thyrſe or cloſe bunch, generally all appearing early in ſpring; and when the flowers fade, the leaves ariſe directly from the root, on ſhort foot-ſtalks near the ground, continuing till autumn, then decay; and the roots remaining, ſend up flowers and leaves again every ſpring; producing alſo abundance of downy ſeeds early in ſummer.

Theſe plants may be employed in gardens for variety, and although they naturally affect moiſt ſituations, they will ſucceed almoſt any where, and will encreaſe abundantly by the root, be of many years duration, and exhibit their flowers annually in ſpring.

But the *Common Tuſſilago*, &c. may alſo be cultivated in beds as medicinal plants.

They are all very eaſily propagated by parting the roots in autumn or ſpring, the ſmalleſt ſlip will readily grow, and ſoon multiply.

# U.

ULEX.
Furze, Gorſe, or Whins.

They are ſhrubby, thorny plants, conſiſting of two ſpecies only; one ſort, *Common Furze*, is a noted, hardy, European ſhrub of heaths and commons, ſometimes cultivated for variety in ſhrubberies, and occaſionally to form field hedges; and the other is a tender exotic ſhrub of Africa, requiring ſhelter of a green houſe here in winter; are both of very branchy, buſhy growth, five or ſix feet high, remarkable for their evergreen ſhoots and branches, armed with ſtrong evergreen ſpines; ſmall, thinly placed, deciduous leaves, and numerous papilionaceous flowers all along the ſides of the young branches.

Claſs and order, *Diadelphia Decandria*.

*Characters.*] CALIX, two oval, oblong, concave, permanent leaves.—COROLLA, is papilionaceous, with five petals, having a large, oval, heart-ſhaped, emarginated vexillum; two ſhort, oblong, obtuſe wings, and a bipetalous carina or keel.—STAMINA, ten diadelphous filaments, having ſimple antheræ.— PISTILLUM, an oblong cylindric germen, a riſing ſtyle, crowned with a ſmall obtuſe ſtigma.—PERICARPIUM, an oblong, turgid, bivalvular, unilocular pod, containing roundiſh ſeeds.

There are only two ſpecies, both of ſhrubby growth, as before ſuggeſted; one of which is hardy and grows wild in all European countries; the other tender. See each below, under its proper head.

*Hardy kind and Varieties.*

Conſiſts of one ſpecies, *Common Gorſe or Whins*, having ſeveral varieties, all ſhrubby, very thorny plants, natives of England, &c.

1 ULEX *Europæus*.

*Common European Ulex, commonly called Furze, Gorſe, or Whins.*] Riſes with upright, hard, woody, whitiſh-brown ſtalks, branching numerouſly and buſhy, five or ſix feet high or more, having green ſhoots and branches, all very cloſely armed with ſtrong green ſpines ſparſedly; ſmall, acute, hairy leaves; and numerous large yellow flowers all along the ſides of the young branches.

*Varieties are.*] Common yellow Furze of our waſtes and heaths.— White flowered Furze.—Long-ſpined Furze.—Short-ſpined Furze.—Large French Furze.—Dwarf Furze —Round podded Furze.

They all flower in March, April, and May, very profuſely, ſucceeded by turgid pods, containing the ſeeds; ripening in autumn.

This ſpecies and varieties are remarkable for having all their young branches, ſhoots, and ſpines of a laſting green colour, but are deciduous in leaf, which come out in the ſpring and ſoon fall off, though from the nature of their numerous branches and ſpines remaining always green, they appear like evergreens, and we have ranked them accordingly in that tribe. See EVERGREENS.

It grows wild on waſtes, heaths, and commons in England and all other countries in Europe, often overſpreading large tracts of ground, ſo is not generally cultivated in gardens, except ſometimes a few in extenſive ſhrubberies for variety and obſervation, and for which purpoſe a few plants of the different ſorts merit admittance in large grounds, both as flowering ſhrubs and evergreens, as they will effect a ſingular diverſity at all ſeaſons.

The Common Furze is likewiſe ſometimes cultivated for outward hedges to fields, generally ſowing the ſeed on the top of dry banks in drills an each deep, where the plants are always to ſtand, ſuffering them to grow up thick quite from the bottom; and will form a cloſe regular hedge, by clipping with garden-ſhears every ſummer, in moiſt weather; though as this kind of hedge, when old, is apt to die off in gaps, become ſtraggling, and naked and hollow at bottom, it is but in ſmall eſtimation; however, thoſe who

who incline it may eaſily raiſe a hedge, by ſowing the ſeed in autumn or ſpring in any light ſoil, in drills as above in the place where the hedge is intended.

*Tender Kind.*

[2] ULEX *Capenſis.*

*Ulex from the Cape of Good Hope, or African Berry-bearing Furze.*] Riſes with a hard ligneous ſtem, branching four or five feet high, having flexible green branches, terminated each with a ſingle ſpine; ſmall, obtuſe leaves ſingly, and numerous flowers along the ſides of the branches.

The flowers of both theſe ſpecies of *Ulex*, and reſpective varieties, are all of the papilionaceous or butterfly kind, and compoſed each of five petals, ſee the *Characters*; and in the Common Furze particularly, the flowers riſe very numerouſly all over the plants, appearing very conſpicuous; ſucceeded by great abundance of ſeed, which is diſcharged from the pods widely around, and fill the ground with many young plants.

If intended to cultivate the Common European Furze and varieties, it may be introduced ſparingly in any of the large ſhrubbery quarters, as before hinted; either raiſe them from ſeed, or procure young plants.

And the ſecond ſort muſt be potted, and placed among the green-houſe plants to have ſhelter in winter.

They are all propagated by ſeed.

Sow that of the firſt ſort either in autumn or ſpring in any light ground, either in patches in the ſhrubbery, where it is deſigned the plants are to remain, or in drills in nurſery beds, and tranſplant the plants while they are quite young, for as they have hard, woody, naked roots, they do not ſucceed well by tranſplantation when grown large.

But when intended to raiſe a Furze hedge, always ſow the ſeed at once in the place where you deſign the hedge to be, in drills an inch deep, ſuffering the plants to remain in the ſame place, being careful to keep them clear from weeds the firſt two or three years till they are a little advanced in growth.

The ſecond ſpecies may alſo be raiſed from ſeed, which muſt be obtained from Africa, its native ſoil; ſowing it in pots and plunge them in a hot-bed, and when the plants are come up, two or three inches high, prick them in ſeparate ſmall pots, and manage them as other green-houſe ſhrubs.

The propagation of this ſort may alſo be tried by layers and cuttings, aſſiſted alſo by plunging the pots of cuttings in a hot-bed or bark-bed.

ULMUS.

Elm Tree.

The Elm is a moſt valuable deciduous timber-tree, of lofty and magnificent growth, and of great eſtimation both as an eminent foreſt-tree, and for various garden plantations, hereafter hinted; ariſes to a very conſiderable ſtature and magnitude, with a large, regular, branchy head, cloſely adorned with oblong, oval, rough, dark-green leaves, and bunches of ſmall apetalous flowers of no beauty, ſucceeded by ſmall roundiſh ſeeds.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, is monophyllous, five-parted at the rim, coloured within, and permanent.—COROLLA, no petals.—STAMINA, five awl-ſhaped filaments, twice the length of the calix, having ſhort, erect, four-furrowed antheræ.—PISTILLUM, an orbicular erect germen, two reflexed ſtyles, terminated by downy ſtigmas.—PERICARPIUM, a large, oval, compreſſed, membraneous, drupaceous fruit, including one roundiſh compreſſed ſeed.

There are only three ſpecies of *Ulmus*, all of the tree kind and deciduous tribe, and all proper for any hardy plantation; though there is only one ſpecies common in England, which, however, comprehends many excellent varieties, conſiſting of the various ſorts of Elms that exhibit themſelves in field hedge-rows, woods, and garden plantations in almoſt all parts of the kingdom.

[1] ULMUS *Campeſtris.*

*Field or Common Elm Tree.*] Riſes with an upright, ſtraight ſtem, and regular branchy head, ſixty or ſeventy feet high or more, covered with a rough bark; largiſh, oblong, oval, doubly-ſerrated, rough, dark-green leaves, unequal at the baſe; and reddiſh or green flowers in bunches towards the ends of the branches; ſucceeded by oval fruit, furniſhing ripe ſeeds the end of May or beginning or middle of June.

*Varieties.*] Common ſmall-leaved Engliſh

Elm.—Larger rough-leaved Engliſh Elm.—Small leaved Corniſh Elm.—Narrow-leaved Wych or Scotch Elm.—Broad-leaved Wych Elm.—Rough-barked Dutch Elm, with large leaves.—Yellow or gold ſtriped-leaved Elm.—Silver ſtriped Elm.—Silver-duſted Elm. All of which are varieties of the ſame ſpecies, having all doubly-ſerrated leaves, unequal at the baſe.

Their principal variation and difference of growth is as below.

*Small-leaved Engliſh Elm.*] Is of fine, ſtraight, lofty growth, branching very numerouſly, regular, and erectly in a beautiful pictureſque manner, very cloſely garniſhed with ſmalliſh oval leaves, and attains a great magnitude.

It is found growing abundantly in the hedge-rows of fields in the ſouth of England, and the counties round London, &c and on account of its lofty ſtature and cloſe, regular, branchy head, is an approved ſort for all garden ornamental plantations, as being the moſt eſtimable for beauty and elegance of growth, of all the varieties of Elm; alſo as a foreſt or timber-tree next in ſize and value to the oak for ſtrength and durability.

The large-leaved Engliſh Elm is diſtinguiſhed from the former by its leaves being broader and rougher.

*Narrow-leaved Corniſh Elm.*] Is alſo of ſtraight handſome growth, almoſt next in ſtature to the Engliſh Elm, branching erect very cloſe and regular, and very cloſely garniſhed with ſmall, oval, lively green leaves.

Is highly valued both for ornamental plantations, and as a foreſt-tree.

*Wych or Scotch Elm.*] Riſes to a great height and magnitude of trunk, with a large, ſpreading, branchy head, having very large, oblongiſh, rough leaves.

Both the varieties of this *Narrow and Broad-leaved Wych Elm*, are alike in their general growth, having much more ſpreading branches than the two former ſorts; are remarkably ſwift growers, and will proſper in almoſt any ſoil, and ſoon attain a ſtately growth, ſo are proper to plant as foreſt-trees and for ornament in parks and other capacious places, and in avenues, &c.

*Dutch or Rough-barked Elm.*] Grows very large, branching irregularly, and widely around, covered with a rough fungous bark; produces large, vigorous ſhoots diſtantly placed; and large, oval, acute-pointed, very rough leaves. Was firſt introduced from Holland many years ſince, and was formerly in much eſteem for forming ornamental hedges in gardens, and other trained devices; but by its ſtrong, irregular, open growth, is improper for ſuch purpoſes, and is much better calculated for planting in parks, fields, avenues, &c. and ſuffered to grow rural; alſo to plant as a timber-tree.

All the varieties of Elm arrive to very large timber-trees, as may be obſerved by old trees growing in parks, hedge-rows, and avenues, and the timber is exceedingly valuable for many ſtrong purpoſes, ſuch as moſt kinds of wheel-wrights work, water-pipes for conducting water under ground, for water-pumps, and various other uſes in different trades, where ſtrength and durability is required; and, therefore, as they are alſo of a free, expeditious growth, and will thrive in any common ſoil, and expoſure; they demand univerſal culture as foreſt-trees, both in aſſembly with other trees of the foreſt kind, and to form woods, thickets, and ranges by themſelves; and to plant in hedge-rows along the borders of fields, and in clumps in the corners thereof; obſerving the Engliſh Elm, Corniſh, and Wych Elms, are the moſt eligible ſorts for general culture as timber-trees; though it is adviſeable to plant ſome of all the varieties to effect the greater diverſity in the plantations; and all of which are eaſily raiſed, ſome from ſeeds, and all of them alſo, both by layers, ſuckers, and by grafting, as hereafter directed, or may be purchaſed very reaſonable at all the public nurſery grounds.

Remarking they ſhould generally be planted out finally while they are young, i. e. from four or five to ſix or eight feet high, as at that ſize they will generally take root, eſtabliſh themſelves, and grow more freely and expeditiouſly than older trees. See PLANTATION.

Though it is obſervable of the Elm, in particular, that they will bear removal when large, better than almoſt any other tree, on account of the root being furniſhed with numerous ſmaller roots and fibres, ſpreading horizontally near the ſurface, ſo as trees of fifteen or twenty feet high or more, may be ſafely removed, as they will often readily riſe with a large ſpread of roots, and frequently with balls of earth thereto; and being

being planted in a capacious pit, will readily ſtrike, and grow freely.

However this removal, or tranſplantation of large Elms, is not an eligible practice for thoſe intended for timber-trees, but only occaſionally in garden-plantations, in places where an immediate ſhade or ſhelter is wanted, or to form a blind where neceſſary, or to hide any diſagreeable object; for all of which purpoſes large Elms may be more readily removed with ſucceſs than any other tree of the deciduous tribe.

But Elms, conſidered for purpoſes in garden-plantations, they are employed occaſionally for ornament, and for ſhade and ſhelter; both as rural objects, and for training uniformly. Conſidered, however, as rural trees, they are excellently adapted for forming avenues, either alone, or in concert with other deciduous trees of loſty ſtature, and to aſſiſt in forming boundary plantations of capacious lawns in parks, &c. likewiſe to form ſhade, by being diſpoſed either in thickets or clumps, or ranged along near the verge of ſhady walks, &c. and are likewiſe excellent to plant for ſhelter, where neceſſary, being planted in groves, thickets, clumps, or ſingle ranges, at a little diſtance, they will break the violence of tempeſtuous winds and cold blaſts, both from the main habitation, and from particular diſtricts of the garden; and have a fine ornamental effect, diſpoſed in extenſive open places, ſome in ſtrait ranges, others in clumps, and ſome as ſingle detached ſtandards; in all of which modes of planting them, they ſhould generally be ſuffered to aſſume their own natural growth, except trimming off large lateral ſhoots from the ſtem, and reducing very irregular ſtraggling branches of the head.

For training uniformly, no deciduous tree is better adapted; they form beautiful loſty hedges, very cloſe from bottom to top, from ten to forty or fifty feet high; the Engliſh and Corniſh elms particularly, and which two varieties were formerly in great repute in forming loſty, towering hedge-work in gardens, both internally, and on the outer boundary, along road ſides, ſerving both for ornament and ſhelter. And Elm hedge-work was alſo often trained into arches, porticoes, pilaſters, galleries, &c. ſo as to produce a very noble effect: and for all which purpoſes of uniform training, the ſmall-leaved Engliſh and Corniſh Elms, above noticed, are conſiderably the beſt calculated, no account of their thick and regularly-branching growth, and cloſe placed foliage. See HEDGES.

All the ſorts of Elm will grow well enough in any common ſoil, but ſucceed beſt in a rich, deep earth, or that of a loamy nature; though we may often ſee large and proſperous Elms on all ſorts of land, both rich and poor, moiſt and dry; generally, however, allowing the Engliſh Elms the beſt ſituations; and the Wych and Dutch Elms may be planted occaſionally on the coarſeſt ſoils.

The ſeaſon for removing or tranſplanting Elms, may be almoſt any time in open weather, from the firſt fall of the leaf in October or November, till March. See PLANTING.

*Method of Propagation, &c.*

The propagation of Elms is effected different ways; as by ſeed, ſuckers, layers, and occaſionally by grafting.

By Seed.—The raiſing of Elms from ſeed, is more particularly practiſed for the Wych Elm, which ripens ſeeds abundantly every ſummer in May or June; the others do not always perfect ſeed in this country; therefore about the end of May, or beginning of June, when the Wych Elm-ſeed is perfectly ripe, let a due quantity be procured for ſowing. Then may proceed to ſow ſome of it almoſt directly, in four-feet-wide beds, half an inch deep, (ſee SOWING SEED); and the reſt may be kept till ſpring, to inſure the greater chance of ſucceſs; previouſly drying it well, out of the ſun, then put it up cloſe, till towards autumn, when it will be proper to mix it with ſand, to preſerve it more effectually through the winter, till the middle of February; then ſow it in beds, as above; remarking of that which was ſowed in ſummer, or as ſoon as gathered, it will be of advantage to hoop the beds over with rods, in order to be covered with mats occaſionally, to afford ſhade from the hot mid-day ſun, giving alſo occaſionally waterings in dry weather; and thus in a month many of the plants will come up, being careful to keep them well weeded, as they may require, and a repetition of moderate waterings, continued in dry weather: though the whole will not probably come up before the following ſpring; but thoſe of the ſpring ſowing generally all come up regularly together the ſame ſeaſon, in April,

April, and often aſſume a freer growth than thoſe which came up in autumn; however, in both caſes ſuffer the ſeedling plants to have one or two years growth in the ſeed-bed, then plant them out in nurſery lines, the rows three feet aſunder, and the plants fifteen or eighteen inches diſtant in each row; here give them the common nurſery care, and train them for the purpoſes intended. If for ſtandards, either for timber, or ornamental plantations, train each to a ſingle ſtem, and as they advance in height, clear the ſtem from all ſtrong lateral ſhoots, leaving only the very ſmall twigs, juſt to draw and detain the ſap, for the better augmentation of the ſtem; ſuffering the leading top-ſhoot to remain entire, as alſo the principal branches of the head.—And thoſe deſigned for hedge-work, &c. let them branch out all the way, and become feathered or branchy to the bottom, or as low as may be required for the trained purpoſes intended, only trimming them occaſionally, either with the knife or garden-ſhears, as you ſhall ſee proper, to give them the intended form.

And thus all the ſorts being trained in the nurſery for the purpoſes intended, till they have four or five years growth, they will be fit for final tranſplantation, where they are to remain.

By Suckers.——Moſt of the ſorts of Elms ſend up many ſuckers from the roots, but moſt plenteouſly in the Engliſh and Dutch ſorts; and which, if taken up carefully with the roots, they will form good plants; therefore in autumn, winter, or ſpring, having recourſe to any large trees that ſend up plenty of ſuckers, let theſe be digged up, with as many fibres as poſſible; and of which chuſing only ſuch that are well rooted, trim them for planting, by cutting them down at top to ſix or eight inches; lay them in ſmall trenches or drills, five or ſix inches deep, one row in each, half a foot apart, and the drills about half a yard aſunder; giving waterings in ſpring and ſummer; and here let them remain two years, to form good roots, then tranſplanted in wide nurſery rows, and managed as directed for the ſeedlings.

By Layers.—All the ſorts of Elms may be eaſily raiſed by layers, previouſly preparing a quantity of ſtools, to produce ſhoots, ſituated near the ground, for laying (ſee STOOLS.) And the proper ſeaſon for laying them is autumn or winter, performing it by ſlit-laying, (ſee LAYERS); and as ſoon as all are layed, and moulded in, top every layer with a knife, down to one eye above ground, and the work is finiſhed.

Thus thoſe layers will readily take root in ſpring and ſummer following, and ſhoot at top probably two or three feet long by the next autumn, when they ſhould be detached from the ſtools, and planted in nurſery rows, a yard aſunder, and half a yard diſtant in the rows; and when they begin to ſhoot, train them with one leading ſhoot only, as obſerved for the ſeedling Elms, managing them in the ſame manner.

By Grafting.—All the varieties of elms may be propagated, and continued diſtinct, by grafting upon ſtocks of the Wych Elm, raiſed from ſeed, ſuckers, or layers, though the ſeedling ſtocks are preferable; and this method of propagation upon the Wych Elm ſtocks particularly, as being the faſteſt and largeſt growers, will be found a good improvement of the other more moderate growers; ſuch as the Engliſh Elm in particular, which being grafted on the Wych Elm, generally attains a larger growth, and ſooner grows to maturity. So that having raiſed a quantity of ſeedling Wych Elms, as before directed, ſome rows of them may be allotted for ſtocks, which, after having two years growth in the nurſery lines, they will be fit to graft; and the latter end of January; or beginning of February, is the proper ſeaſon: at which time having procured a quantity of cuttings of young moderate ſhoots of the beſt Engliſh Elm, or any other variety you intend to propagate, and cut into four or five-inch lengths, proceed to inſert them in the ſtocks by the method of whip-grafting. (See GRAFTING.) Obſerving, however, as it is moſt adviſeable, to graft them as low as poſſible, the earth ſhould be removed away a little down to each root, then cutting off the head of the ſtock within two or three inches of the bottom, inſert the grafts one in each ſtock, as above, binding them cloſe, and clay them well; then draw the earth up about, and over the clay, the more effectually to ſecure it from falling off by the effects of froſt, &c.

Being thus grafted, the grafts will unite timeouſly the ſame ſpring, and ſhoot forth ſtrongly in ſummer, half a yard, or two or

three

three feet in length; obſerving to encourage only one leading ſhoot; ſo that if they fork at top into two or more ſhoots, take off the weakeſt, and leave the beſt ſhoot for the leader; diſplacing alſo all large ſide-ſhoots from the ſtem; and let the top or leading ſhoot remain always entire, as alſo the general branches of the head grow in height as faſt as they can, agreeable to the nature of their growth, eſpecially all thoſe intended for ſtandards.

UMBELLA. An Umbel of flowers.

It is a mode of cluſter-flowering; many flowers being produced cloſe together on ſo many ſlender foot-ſtalks, proceeding all from one point, or common center, and riſe all to an equal height; ſo as the flowers they ſupport forms generally an even round ſurface at top, ſuch as in the flowers of *angelica*, carrot, parſnip, &c.

The umbellate mode of flowering differs from the *corymbus*, in which the foot-ſtalks alſo elevate the flowers to an equal height at top, reſembling an Umbel. The foot-ſtalks of the umbellate flowers iſſue all from one centre or point of the common receptacle, attaining all nearly an equal length and height; whereas thoſe of the *corymbus* riſe from different points, lower and higher, and each lower foot-ſtalk attains a greater length than that immediately above it; ſo as they altogether, with the flowers at top, form alſo an even ſurface, like the umbellate flowers. See CORYMBUS.

In the umbellate flowers, when none of the foot-ſtalks of the Umbel are ſubdivided, it is termed a Simple Umbel; when on the other hand each flower-ſtalk is ſubdivided at its extremity into a number of ſmaller foot-ſtalks, that immediately ſupport the flowers, ſo as each ſuch foot-ſtalk bears at top a little Umbel, commonly called partial Umbels, and that the main or general Umbel, or aggregate, being made up of ſeveral ſuch ſmaller ones, it is termed a compound Umbel.

Umbellate flowers are generally produced at the top of the ſtalks, and extremity of the branches of the plants of the umbelliferous tribe.

The flowers that compoſe an Umbel are generally numerous, and ſeparately ſmall, conſiſting each commonly of five petals, five ſtamina, and two ſtyles, and each flower is ſucceeded by two naked ſeeds.

UMBELLIFEROUS plants are ſuch as produce their flowers in an Umbel, and conſiſt both of herbaceous vegetables and trees, but moſtly of herbaceous plants.

The principal of which are, angelica, carrot, parſnip, parſley, celery, fennel, dill, chervil, fennel-giant, lovage, Alexanders, coriander, carraway, black maſter-wort, Macedonian parſley, ſamphire, burnet, ſaxifrage, &c. all of which being of the Umbelliferous tribe, moſtly riſe with erect, hollow ſtalks, generally branching in the alternate way; the leaves alſo are placed alternate; which in ſome are ſimple, in others fingered, and ſome pinnated or winged; and all the ſtalks and branches generally terminate in an Umbel of flowers, either ſimple or compound, in the different plants. See each in its proper genus.

Of this tribe of plants, ſeveral of them are valuable eſculents of the kitchen-garden, and ſome are wholeſome medicinal plants. See KITCHEN-GARDEN and MEDICINAL PLANTS.

URTICA. Nettle.

This genus conſiſts of hardy, herbaceous plants, ſome of which are well known as common and troubleſome weeds in gardens; and one or two ſpecies of foreign growth are retained in ſome gardens, to effect variety; riſes with upright ſtalks, adorned with oblong and oval leaves, and monoecious flowers, without petals, growing in catkins at the ſides, and top of the ſtalks.

Claſs and order, *Monoecia Tetrandia.*

*Characters.*] CALIX, male and female; flowers ſeparated on the ſame plant, having in the males a four roundiſh-leaved cup; and in the females an oval cup, compoſed of two valves, and is permanent.——COROLLA, no petals, but in the males is a pitcher-ſhaped nectarium in the center of the flower.——STAMINA, four awl-ſhaped ſpreading filaments, having bilocular antheræ.—PISTILLUM, an oval germen, (no ſtyle) and a hairy ſtigma.——PERICARPIUM, none; a ſingle, oval, compreſſed ſeed lodges in the permanent female calix.

There are many ſpecies of *Urtica*, and of which two of them are common in the gardens, retained as plants of variety; the other being plants of but little uſe or eſtimation, and ſome of them are common weeds; ſuch as the common Stinging Nettle, which grows too faſt every where, are never cultivated; the common Nettle however has great virtues

tues as a medical plant, and is alſo in eſtimation as an excellent pot-herb among poor country people, in the ſpring, while it is young; and is of a very wholeſome, cleanſing property.

The moſt material ſorts in our gardens are the following two, both of foreign growth, but are hardy enough to ſucceed here in the full ground.

[1] URTICA *Cannabina.*

*Hemp Urtica, commonly called Tartarian Nettle.*] Hath a perennial fibrous root, ſending up many ſquare ſtalks, five or ſix feet high; having oblong, three-parted, deeply-cut leaves, placed oppoſite; and flowers produced in long catkins at the axillas, towards the upper part of the ſtalks.

It grows naturally in Tartary and Siberia.

[2] URTICA *Canadenſis.*

*Canadian Nettle.*] Hath a fibrous, perennial root, ſending up erect ſtalks, two feet high; adorned with heart-ſhaped, oval leaves, placed alternately; and flowers produced in branching amentums, growing erect.

[3] URTICA *Cylindrica.*

*Cylindrical-flowered American Nettle.*] Hath a fibrated, perennial root; upright ſtalks, three feet high; oblong, ſpear-ſhaped, oppoſite leaves; and flowers produced in cylindric, undivided, ſolitary amentums.

All theſe plants are perennial in root, ſending up new ſtalks annually in ſpring, flowering in July and Auguſt, and the ſeeds ripen in autumn.

They are all hardy plants, and ſucceed in any common ſoil.

They are retained in our gardens, to diverſify the herbaceous collection, and effect variety in the pleaſure-ground; and may be planted in any of the open borders, and other compartments, and in which they will endure many years, and flower annually; though their flowering is more ſingular than beautiful.

Propagate them by parting the roots in autumn, winter, or early in ſpring.

---

# V.

VALVULA. A Valve, or opening of a ſeed-veſſel.

A Valve is the external diviſion or opening of a dry ſeed-veſſel, ſuch as a capſule or pod, which when ripe ſplits into two or more openings, to diſſeminate the ſeeds, and each opening or diviſion is called a Valve.

The Valves or openings, as to number, are from one or two to five or many, in the plants of different genera; ſo that when a a capſule, &c. is compoſed of one Valve, it is termed *univalve*; of two, *bivalve*; when of three, *trivalve*; four, *quadrivalve*; and of five, *quinquevalve*, &c. See CAPSULA.

VALERIANA. Valerian.

The plants are hardy, herbaceous perennials and annuals; ſome for variety in the pleaſure-garden, and others for medical and eſculent uſes; all of the fibrous-rooted kind, ſending up annual ſtalks, two or three feet in the perennials, the other but a few inches; ornamented with ſimple and pinnated leaves in the different ſpecies; and terminated by ſpikes, or umbellate cluſters of monopetalous, five-parted flowers.

Claſs and order, *Triandria, Monogynia.*

*Characters.*] CALIX, a kind of ſmall border placed on the germen.—COROLLA, is monopetalous and tubulous, with the tube gibbous, and divided above into five obtuſe ſegments.——STAMINA, three awl-ſhaped, erect filaments, having roundiſh antheræ.—PISTILLUM, a germen under the corolla, filiform ſtyle, and thick ſtigma.—PERICARPIUM, a coronated or crowned deciduous capſule, falling off before it opens, containing a ſingle oblong ſeed.

There are about eighteen ſpecies; and the moſt material of which commonly cultivated are the following five, the firſt four being flowery and medical perennial plants, and the laſt is an eſculent annual, uſed as a ſal-

lad

lad herb, commonly called Corn-Sallad, or Lamb's Lettuce.

[1] VALERIANA *Rubra.*

*Red Valerian.*] Hath a thick, ligneous, ſpreading, perennial root; upright, round, ſmooth ſtalks, branching two or three feet high; adorned with ſpear-ſhaped, entire leaves; and the ſtalk and all the branches terminated by cluſters of red flowers, having tails.

*Varieties.*] Deep red-flowered—Pale red-owered—White-flowered—Narrow-leaved (*anguſtifolia*) with bright-red flowers,

They all flower in May or June; continuing in ſucceſſion moſt part of ſummer, appearing tolerably ornamental; and ripen abundance of ſeed in autumn, which is often ſcattered by winds all around, and in crevices of old buildings, &c. and from which many young plants naturally riſe, and attain maturity.

[2] VALERIANA *Phu.*

*Phu, or Garden Valerian.*] Hath thick, fleſhy, jointed, fibrous, creeping, perennial roots; crowned with numerous leaves, moſtly entire, and ſome divided; amidſt them upright, round ſtalks, branching two or three feet high, garniſhed with pinnated leaves, and with all the ſtalks and branches terminated by umbel-like cluſters of white flowers, having only three ſtamina; appearing in May and June.

[3] VALERIANA *Officinalis.*

*Wild officinal Valerian.*] Hath long, fleſhy, fibrous roots, collected into heads; crowned with many winged leaves; upright ſtalks, two feet high, garniſhed alſo with pinnated leaves, and all the ſtalks and branches terminated by umbel-like cluſters of flowers, tinged with purple, having only three ſtamina; flowering in May or June.

[4] VALERIANA *Pyrenaica.*

*Pyrenean Mountain Valerian.*] Hath fibrous perennial roots; crowned with large heart-ſhaped, ſerrated leaves, on long foot-ſtalks; amidſt them upright, channelled ſtalks, a yard high, garniſhed with ſmaller heart-ſhaped leaves, ſometimes by three together, near the top, and the main ſtalk and branches crowned with umbel-like bunches of pale-red flowers, having three ſtamina; flowering in June.

[5] VALERIANA *Locuſta* (*annual*).

*Locuſta, or Lamb's Lettuce, commonly called Corn-Sallad.*] Hath fibrous annual roots; crowned with ſmall, oblong, narrow leaves, broadeſt and rounded at the top; and when it ſhoots for ſeed, riſes with a forking, ſlender ſtalk, only a few inches high, garniſhed with ſmall leaves, and terminated by cluſters of ſmall white flowers, having only three ſtamina.

This grows naturally in corn-fields in England, &c. hence is commonly called Corn-Sallad, as being uſed as a ſallad herb; and as ſuch it is alſo cultivated in gardens for winter and ſpring uſe.

*Varieties.*] There are many varieties of this, differing in the form and ſize of the leaves; ſome being very narrow, others broader and obtuſe, or oblong and ſpear-ſhaped; ſome being entire, and ſome are ſerrated or indented, &c. but poſſeſs all the ſame virtues, and may be indifferently uſed as ſallad herbs, to uſe while young, before they grow large and rank taſted; and they prove ſubſtitutes in winter and ſpring ſallads, when the garden-lettuce is ſcarce.

All theſe five ſpecies are very hardy plants, and proſper in any common ſoil of a garden, in all ſeaſons of the year.

The firſt four are perennials, durable in root, and annual in ſtalk, which riſe from the root every ſpring, flower in May or June, ripen ſeed abundantly in Auguſt, then decay down to the ground.

All theſe four perennial ſorts may be employed in the pleaſure-ground, for ornament and variety; and the ſecond and third ſort alſo as medical plants, and as ſuch are highly valued: may be all had at the public nurſeries in the proper planting ſeaſon, autumn, winter, or ſpring; and may all be planted in any of the open compartments, in aſſemblage with other large herbaceous perennials; where they will endure for years by the root, and flower annually in their proper ſeaſon, and multiply abundantly by the root; and may alſo be raiſed from ſeed. See their *Propagation.*

However, the ſecond and third ſorts, *Valeriana Phu* and *Valeriana Officinalis* being alſo very valuable medical plants, if intending to cultivate them as ſuch, they ſhould be diſpoſed in beds among other medicinal herbs.

But as to the fifth ſort, *Valeriana Locuſta*, an annual, it is calculated only as an eſcu-

lent herb in ſallads, principally in winter and early ſpring; being ſowed in autumn towards the latter end of Auguſt, and in September, in any open ſituation, and raked in, they will come up the ſame year, thinning the plants to three or four inches, and they will be fit for uſe in winter and ſpring following: ſome may alſo be ſowed early in the ſpring, to continue a longer ſucceſſion.

VARIETAS.

A Variety.

Varieties are the off-ſpring of certain ſpecies, varying in ſome accidental habit of growth from the natural ſpecies or parent plant; yet their variation being generally confined to ſome particular parts, they ſtill retain the ſpecific mark of diſtinction of the parent, to diſtinguiſh them from plants of a different ſpecies.

So that a ſpecies often compriſe from one or two, to ſome hundreds of Varieties, varying in ſome particular, either in their habit of growth, foliage, flowers, fruit, œconomical qualities, &c. and both trees and herbs, annuals, biennials, and perennials are ſubject to variation.

For example, ſpecies are ſubject to numerous accidental modes of variation, effected either by the difference of culture, climate, ſoil, age, &c. and conſiſt often in the difference of magnitude; luxuriant, and dwarf growths; erect, and trailing plants; ſmooth and prickly Varieties; broad and narrow-leaved kinds; entire-leaved, divided-leaved, and curled-leaved; ſpotted, and variegated-leaved; ſmooth-leaved, hairy-leaved, and downy-leaved plants; ſingle-flowered, double-flowered, and proliferous flowered; white, red, blue, yellow, and variegated-flowered; ſweet-ſcented, rank-ſcented, &c. Likewiſe the fruit in ſome ſpecies are liable to great variations; as round fruit, oval fruit, oblong fruit; alſo ſmooth fruit, furrowed fruit, warted fruit, hairy and downy fruit; likewiſe fruit varying greatly in ſize, in the ſame ſpecies; likewiſe in colour, taſte, and quality: in ſome ſpecies alſo, the root is found to vary, as in the carrot, radiſh, turnep, and potatoe, which often aſſume different forms and colours; and ſome ſpecies furniſh both male and female Varieties in different plants, as in the dioecious claſs; thus the above, and numerous other circumſtances occur in the various forms of ſporting nature, in exhibiting ſo many different Varieties in certain ſpecies.

But notwithſtanding all the above different modes of variation in the particular parts of the variating plants of a ſpecies, if thoſe of each ſpecies ſtill all retain the ſame ſpecific botanic mark of diſtinction, as that which diſtinguiſhes the reſpective natural ſpecies from all others, it proves them all Varieties or off-ſpring of the ſame parent ſpecies.

For as every different ſpecies in a genus is diſtinguiſhed by ſome particular uniformly conſtant mark in ſome part of its growth, all plants in the ſame genus bearing exactly the ſame ſpecific mark of diſtinction unchangeably, are, notwithſtanding their accidental variation in other parts of their growth, all Varieties of one ſpecies.

Therefore, all the plants that are produced from the ſeed of the ſame ſpecies, although they may aſſume different forms and appearances, are to be regarded as the genuine Varieties.

The difference betwixt a ſpecies and a Variety is, that a true ſpecies raiſed from ſeed, will, notwithſtanding it may ſport into different variations, it ſtill retains its true and conſtant ſpecific mark through all its Varieties; and ſuppoſe there are Varieties of that ſpecies with broad leaves, and narrow leaves, white flowers, red flowers, and blue flowers, &c. and that if you ſow the ſeed of any one, it will probably produce ſeedling plants of all theſe ſorts.

It is principally from ſeedling plants that the different Varieties of particular ſpecies firſt obtain, exemplified in the *auricula*, *polyanthus*, &c. each being a diſtinct ſpecies of the ſame genus; and each conſiſts of innumerable Varieties, in the colours and variegations of the flowers, all firſt obtained from ſeed; which from that of the ſame plant, often ſport into many different colours and variegations in the flower; each variation forming a genuine variety; and probably not one of them with a flower exactly like that of the original parent plant: yet each Variety retains the ſpecific difference of its reſpective ſpecies, the auricula never changing to the polyanthus, nor that to the auricula, but the varieties of each keep their proper diſtinction; for the auricula in all its Varieties, continues its *ſmooth*, *fleſhy*,

*fleſhy, ſerrated leaves*; and the polyanthus, its *rough dentated leaves*. The ſame is alſo obſervable of the carnation, ranunculus, anemone, tulip, and numerous other plants, which ſport wonderfully in Varieties.

Likewiſe numerous ſorts of trees, of the fruit kind particularly, are remarkably ſportive in Varieties; both in their modes of growth, foliage, and fruit: for example, the botaniſts admit of only one ſpecies of apple-tree, which however furniſhes an almoſt endleſs Variety of its fruit, in regard to ſhape, ſize, colour, taſte, and quality; as alſo in the growth of the trees, differing both in magnitude and ſize, as well as in the ſize and colour of the foliage; and its ſpecific diſtinction is, *ſerrated leaves, and cloſe ſitting flowers growing in an umbel*, which diſtinction runs through all the numerous Varieties, however different the trees may be in magnitude of growth, leaves, and fruit: the ſame is alſo obſervable of the pear, plum, common-cherry, peach, &c. there being only one ſpecies of each of theſe, but the Varieties of the fruit are very numerous; all of which different variations of the above ſorts of trees were firſt obtained from ſeedlings; i. e. trees raiſed from the kernels or ſtones of the fruit; and almoſt all the fruit-tree kind ſport exceedingly in their ſeedling plants; inſomuch, that out of hundreds of trees raiſed from the ſeeds of the beſt fruits, very few, if any, will produce fruit exactly like the parent, or that poſſeſs any good perfection; ſo that on account of the uncertainty of continuing the approved ſorts of fruits from ſeedling plants, recourſe is always had to grafting and budding to propagate the ſorts intended, or to continue and encreaſe any new-acquired good Variety.

The greater number of varieties, both of herbaceous plants and trees, are of a variable or ſporting nature; ſo as when raiſed from ſeed there is no dependence on having the ſeedlings come the ſame ſort again, but vary into different ſorts of one another; in which caſe, the propagation of thoſe that are perennial, to continue them with certainty, is effected either by ſuckers, off-ſets, or ſlips of the root; or, in the woody kinds, by layers, cuttings, grafting, and budding: but as to annuals, there is no other reſource for propagating them than by ſeed, except in ſome few ſorts by cuttings, ſuch as the *Chryſanthemum* and *Naſturtium*, &c. but in many ſorts where particular attention is obſerved in ſaving the ſeeds, always only from the moſt perfect kinds, they will continue tolerably permanent, and often come the ſame again, or but with very little variation.

Many of the kitchen-garden plants and annual flowers, conſiſt of many Varieties in the ſame ſpecies; yet by good care in always ſaving ſeed from the moſt perfect plants that diſcover no ſigns of a degeneracy, they remain permanent from ſeed year after year.

However, moſt of the perennial tribe, both herbaceous and woody kinds, as they being generally more variable from ſeed, they afford abundant opportunities to continue the permanency of any particular Variety, by off-ſets from the root, ſuckers, layers, cuttings, grafting, and budding, as before noticed.

Sometimes, however, plants though not raiſed immediately from ſeed, will from ſome accidental cauſe vary conſiderably from their natural growth, and aſſume a very different appearance; originating either through culture, climate, expoſure, ſoil, age, diſeaſes, luxuriancy or poverty of nouriſhment, contuſions, or other circumſtances; and hereby produce accidental Varieties in ſome particular parts of growth.

As to the determining the reality of the Varieties, it is in many ſorts moſt eaſily accompliſhed by comparing the variable plant with the ſpecific deſcription of the natural ſpecies, and the variations of growth of the variety with the ſame parts in the natural plant; though there are many varieties that require both knowledge and experience of the moſt expert botaniſt to diſtinguiſh them with certainty.

From not obſerving the true ſpecific diſtinction, Varieties have been ranged as diſtinct ſpecies, and thereby exceedingly encreaſed the number of ſpecies erroneouſly, and cauſed great confuſion in the true botanic arrangement; for on account of the ſlighteſt difference new ſpecies were introduced, which modern improvers of botany diſcovered to be only Varieties of certain

pecies, and have corrected the errors accordingly.

Therefore, in botanic arrangements, we ought to be careful not to ſubſtitute a Variety in the room of a ſpecies, which being ſometimes a difficult point, requires the greateſt care; and the cauſe of our running into ſo many errors in this particular, is owing to nature's working and appearing in ſo many different forms, either through the nature of different countries, climates, ſoils, expoſures, and culture, &c. as before obſerved.

We have, however, in the courſe of the arrangement of the numerous articles in this book, been careful to collect the different Varieties under their reſpective ſpecies, exhibiting at once each ſpecies and its Varieties, when any, arranged diſtinctly together under their proper genera.

VERATRUM. White Hellebore.

This genus is compoſed of hardy herbaceous perennials for ornament and variety in the pleaſure-ground, and for medicinal uſe; are of the fibrous and tuberous-rooted tribe, riſing with upright annual ſtalks, ſome a yard or more high, others hardly a foot; garniſhed with large, oblong, and ſpear-ſhaped, nervous leaves; and all the ſtalks and branches terminated by ſpikes of cloſely-placed hexapetalous flowers.

Claſs and order, *Polygamia Monoecia.*

*Characters.*] CALIX, hermaphrodite and male flowers on the ſame plant, all without any calix.—COROLLA, ſix oblong, ſpear-ſhaped, ſerrated, permanent petals.—STAMINA, ſix awl-ſhaped filaments, having quadrangular antheræ.—PISTILLUM, three oblong, erect germens, terminating in a very ſhort-ſtyle; which in the males is ſcarce viſible, and ſimple ſtigmas.—PERICARPIUM, three oblong, erect, compreſſed, univalvular, unilocular capſules, opening on the inſide; containing many oblong, compreſſed, membranaceous ſeeds.

There are only three ſpecies, all very hardy perennials; the two firſt of which are tall growing plants, with large broad leaves; and the third is of much lower growth and narrower leaves, as in their deſcriptions below.

[1]VERATRUM *Album.*

*White-ſpiked Ruſſian Veratrum, or Common White Hellebore.*] Hath a thick, fibrated, perennial root, crowned with large, oblong, oval, nervoſe leaves, near a foot long, and half as broad; upright, round, thick, very branchy ſtalks, three or four feet high; garniſhed with leaves diminiſhing gradually upward; and all the ſtems and branches terminated by decompound or ſubdivided ſpikes of whitiſh-green, cloſely-placed flowers, having erect petals; appearing in May and June.

It inhabits the mountains of Ruſſia, Siberia, and Auſtria, &c. but hath been introduced into the Engliſh gardens, both as an ornamental and medical plant.

[2]VERATRUM *Nigrum.*

*Black-ſpiked Hungarian Veratrum.*] Hath a thick, fibrous, perennial root; crowned with large, long, nervous, yelloviſh-green leaves; upright, thick ſtalks, branching four or five feet high, garniſhed with a few leaves; and with all the branches terminated by compound, leſs-divided ſpikes of dark-red flowers, having ſpreading petals; appearing in June and July.

It grows naturally in Hungary and Siberia.

[3]VERATRUM *Luteum.*

*Yellow-ſpiked Virginia Veratrum.*] Hath a bulb-like tuberous root, ſending up oblong, ſpear-ſhaped, nervoſe leaves, ſpreading cloſe to the ground; an upright ſingle ſtalk, about ten inches or a foot high; garniſhed with a few cloſe-ſitting leaves, and terminated by a cloſe, ſingle ſpike of yellow flowers; in June and July.

All theſe three ſpecies are hardy herbaceous plants, durable in root, but annual in leaf and ſtalk, which riſe in ſpring; the leaves riſing large, broad, and folded, aſſume a ſingular appearance; and between them the flower-ſtalks of thick, robuſt growth, riſing to a flowering ſtate in May, June, and July; having all the branches terminated by the ſpikes of flowers, which ſingly are rather ſmall; but are collected numerous and cloſe in each ſpike; ſucceeded by ripe ſeeds in autumn, in the firſt and ſecond ſort particularly; and ſoon after the ſeeds are ripe, the ſtalks decay.

Theſe plants have been long inhabitants of the Britiſh gardens, for variety and medical purpoſes; particularly the firſt and ſecond ſorts.

They all ſucceed in any common ſoil and expoſure.

As

As to their general merit as ornamental plants, or for variety, &c. they having great ſingularity in their large furrowed leaves, as well as in their different modes of flowering; they demand culture in every herbaceous collection, diſpoſed in the open borders and other compartments of the pleaſure-ground; in which they will effect a moſt agreeable diverſity, in ſpring and ſummer.

Likewiſe, as medical plants, the firſt ſort in particular *(Veratrum Alba)* is in great repute: the root of which forms a powerful ſternutatory powder; and for which purpoſe, the plants may be planted in any bed or border of common earth.

The propagation of all the three ſpecies is by ſeed, and by parting the roots.

By Seed.—This may be ſowed either in autumn, ſoon after it is ripe, or in ſpring, in a bed of light earth, and raked in; and they will come up in April or May, giving occaſional watering and weeding; and in July or Auguſt, prick them out in nurſery-rows, to remain a year or two to grow ſtrong; then tranſplanted where they are to remain.

By parting the Roots.—Autumn, when the leaves decay, or early in ſpring, before new ones ſhoot forth, is the proper period; when the roots may be divided into ſeveral ſlips, not too ſmall, and planted at once where they are always to ſtand.

## VERBASCUM.

Mullein.

The plants are hardy, herbaceous, perennials, biennials, and annuals, proper to diverſify the borders and other compartments of the pleaſure-ground as flowery plants; alſo for medicinal preparations; all of the fibrous-rooted tribe, ſending up erect ſtalks, moſtly tall; from two or three, to four or five feet ſtature; and ſome of much lower growth, garniſhed in the different ſorts with oblong, and oval leaves; and monopetalous, rotaceous flowers in ſpikes, and ſingly at the ſides, and ends of the branches.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, is ſmall, monophyllous, acutely five-parted, and permanent.—COROLLA, is monopetalous, wheel ſhaped, with a very ſhort cylindric tube, and ſpreading brim cut into five oval ſegments.—STAMINA, five awl-ſhaped, declinated, ſhortiſh filaments; having roundiſh, compreſſed, erect antheræ.—PISTILLUM, a roundiſh, germen, filiforme, inclinating ſtyle; and a thickiſh, obtuſe ſtigma.—PERICARPIUM, a roundiſh, bilocular capſule opening at top, and numerous angular ſeeds.

There are about eleven ſpecies of *Verbaſcum*, ſome perennial, others biennial and annual, as before noticed; and the moſt material ſorts thereof are the following; though the firſt three or four ſorts are the moſt common in the Engliſh gardens.

[1]VERBASCUM *Ferrugineum. (Perennial.)*

*Ferrugineous, or Iron-coloured Moth Mullein*] Hath a perennial root; oval, oblong, ſlightly-crenated leaves; upright ſtalks, three or four feet high, terminating above in long looſe ſpikes of yellowiſh iron-coloured flowers.

[2]VERBASCUM *Nigrum. (Perennial.)*

*Black Mullein with a yellowiſh-purple flower.*] Hath a perennial root; oblong, heart-ſhaped, foot-ſtalked leaves, eight or ten inches long, hoary underneath; upright, angular ſtalks, four or five feet high, garniſhed with a few narrow leaves, and terminated by long ſpikes of yellow flowers with purple antheræ.

It grows by way ſides, &c. in England, and moſt parts of Europe.

[3]VERBASCUM *Phœniceum. (Perennial.)*

*Phœnician Purple Moth Mullein.*] Hath a perennial, and ſometimes a biennial root; ſending up oval, crenated, rough-ſpreading leaves; an upright ſtalk about three feet high, almoſt naked of leaves; and purpliſh flowers along the ſide of the ſtalk and branches.

[4]VERBASCUM *Myconi. (Perennial.)*

*Verbaſcum Myconi, or Borage-leaved Mullein*] Hath a perennial root; crowned with oval, thick, woolly leaves ſpreading flat on the ground; ſlender, naked foot-ſtalks four or five feet high, divided upward into ſmaller, each terminated by one large blue flower. Is a native of the Pyrenees.

[5]VERBASCUM *Thapſus. (Biennial.)*

*Thapſus or Great White Mullein.*] Hath a biennial root; long, broad, whitiſh leaves, woolly on both ſides; an upright, thick, firm ſtalk, five or ſix feet high, garniſhed with decurrent, woolly leaves, and terminating above in a long thick ſpike of yellow flowers.

It

It grows naturally in England, &c. by way-ſides, and other uncultivated ſterile places; but ſometimes retained in gardens for variety, and as a medicinal plant.

[6] VERBASCUM *Sinuatum. (Biennial.)*

*Sinuated Mullein.*] Hath a biennial root; oblong, ſinuated, pinnated leaves; an upright, firm ſtem, four or five feet high, having the primary or firſt branches oppoſite, and garniſhed with oblong, amplexicaule, naked leaves; and cluſters of yellow flowers along the ſides of the branches. Grows naturally in France and Italy.

[7] VERBASCUM *Phlomoides. (Biennial.)*

*Phlomoide Mullein with a large Yellow Flower.*] Hath a biennial root; oval leaves, woolly on both ſides; an upright, purpliſh ſtalk, four or five feet high; garniſhed with ſmall, oval, hoary leaves, the lower ones having foot-ſtalks; and the ſtalks terminating in thick ſpikes of large, yellow flowers. Grows naturally in Italy.

[8] VERBASCUM *Lychnitis. (Biennial.)*

*Hoary white Mullein.*] Hath a biennial root, large, oblong, wedge-ſhaped, woolly leaves; an upright ſtalk, three or four feet high, garniſhed with white leaves, and ſmall white flowers in ſpikes at the joints and ends of the ſtalk and branches. Grows in England, &c. in ſandy, chalky ſituations.

*Variety.*] With yellow flowers.

[9] VERBASCUM *Blattaria. (Annual)*

*Blattaria, or Amplexicaule-leaved Moth Mullein.*] Hath an annual root, upright ſtalk four or five feet high; oblong, ſmooth, ſinuated, complexicaulous leaves; and yellow flowers ſingly along the ſides of the ſtalk and branches.—Grows naturally in England, &c.

*Variety.*] With white flowers.

All theſe nine ſpecies of the *Verbaſcum*, are of the herbaceous tribe; the firſt four are perennials with durable roots, the next four biennials, and the laſt of all is an annual; all of which riſe with erect ſtalks in the ſpring, attaining to full height, and flower in June and July: in all of which the flowers are monopetalous and five-parted; and produced in ſpikes and other modes of flowering, as in their reſpective deſcriptions; are moſtly of an odoriferous nature, and are ſucceeded in moſt of the ſorts, by ripe ſeeds in Auguſt or September.

They are all very hardy plants, that will proſper in any common ſoil and expoſure in the common borders, &c. of a garden.

Conſidered as garden plants, they merit admittance, to diverſify the large borders and other ſimilar compartments of the pleaſure-ground; particularly the larger ſorts, which though not ſo ornamental as ſome, yet by their different foliage, luxuriant ſtems, and different colours and modes of flowering, they will effect a conſpicuous variety.

*Method of Propagation.*

They are propagated by ſeed and off-ſets of the roots.

By Seed.—Sow it either early in autumn or ſpring, in a bed or border of light earth, and raked in: and when the plants are come up three inches high, plant them out either in the borders to remain, or in nurſery-lines till autumn, then tranſplanted finally; though the annual ſort ſhould be planted out early in ſummer to remain, or ſowed at once in patches where the plants are intended to ſtand.

By Off-ſets.—All the perennial ſorts furniſh off-ſets from the ſides of the roots, which may be detached in autumn, or early in the ſpring, and planted either where they are to remain to flower, or in nurſery-rows till autumn, then removed to their borders, &c.

## VERONICA.

Speedwell.

This genus conſiſts of many herbaceous perennials, &c. ſome of them retained in gardens for variety; riſing, ſome with trailing, and others with erect ſtalks, from five or ſix inches, to ſo many feet high; adorned moſtly with ſmalliſh, oval, oblong, and ſpear-ſhaped leaves, and of other different forms in the ſeveral ſpecies; and monopetalous, wheel-ſhaped, four-parted flowers, in ſpikes and bunches at the ſides and ends of the branches.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is divided into four ſpear-ſhaped ſegments, and permanent.—COROLLA, is monopetalous, wheel-ſhaped, and divided above into four oval ſegments.—STAMINA, two riſing filaments, with oblong

oblong antheræ.—PISTILLUM, a compreſſed germen, ſlender declining ſtile, and ſimple ſtigma. — PERICARPIUM, a heart-ſhaped, compreſſed, quadrivalve, bilocular capſule, having many roundiſh ſeeds.

There are upwards of thirty ſpecies of *Veronica*, moſtly herbaceous perennials and annuals; a few of the former are the moſt remarkable, ſome as medical plants, and for variety; others as flowery ornamental plants to decorate the compartments of the pleaſure-ground, and are moſtly all of the fibrous-rooted tribe; ſome natives of England, and ſome are exotics from different diſtant parts of Europe and America; and are of hardy growth.

[1] VERONICA *Officinalis.*

*Common Officinal Speedwell of the Shops.*] Grows with low procumbent ſtalks, rooting at the joints; oval, ſerrated leaves, placed oppoſite; and the ſtalks terminated by ſpikes of ſmall blue flowers.

It is a native of woods, commons, and ſterile paſtures in England, &c. and is a valuable medicinal plant.

[2] VERONICA *Serpyllifolius.*

*Mother-of-Thyme-leaved Speedwell, or Paul's Betony.*] Hath trailing ſtalks, branching and rooting at the joints; ſmall, oval, ſmooth, crenated leaves; and white flowers in racemous ſpikes terminating the branches.

It inhabits moiſt meadows in England, &c. and is ſometimes uſed in medicine.

[3] VERONICA *Hybrida.*

*Hybridaceous Speedwell, or Welſh Veronica.*] Riſes with an erect, branchy ſtalk, eight or ten inches high; oblong, obtuſe, ſerrated, rough leaves, placed oppoſite; and the ſtalks and branches terminated by long ſpikes of blue flowers. Grows on the mountains in Wales, &c.

[4] VERONICA *Siberia.*

*Siberian Septifolious Veronica.*] Riſes with upright, firm, hairy ſtems, four or five feet high; broad, oval, ſpear-ſhaped leaves, by ſevens, ſurrounding the ſtalk in a verticillus; and the ſtalks terminated at top by long ſpikes of blue flowers.

[5] VERONICA *Virginica.*

*Virginian Quaternate-leaved Veronica.*] Riſes with upright ſtalks, four or five feet high; garniſhed with ſpear-ſhaped, quaternate, and quinate leaves; and terminated by long ſpikes of white flowers.

[6] VERONICA *Auſtriaca.*

*Auſtrian Blue Veronica.*] Riſes with upright, branchy ſtalks, three feet high; linear-ſpear ſhaped leaves, cut pinnatedly; and ſpikes of blue flowers at the ſides of the ſtalk and branches.

[7] VERONICA *Maritima.*

*Maritime or Sea Veronica.*] Riſes with erect ſtalks two feet high; ſpear-ſhaped, unequally ſerrated, ternate leaves; and the ſtalks terminated by ſpikes of bright-blue flowers. Grows near the ſea in ſeveral parts of Europe.

[8] VERONICA *Incana.*

*Hoary Tartarian Speedwell of Ucrania.*] Riſes with an erect, hoary ſtalk, a foot high; oblong, crenated, hoary, oppoſite leaves; and the ſtalks terminating in erect ſpikes of blue flowers.

[9] VERONICA *Teucrium.*

*Germander Speedwell.*] Riſes with erect ſtalks, three or four feet high; oval, obtuſe, indented, rough leaves; and long ſpikes of blue flowers at the ſides of the branches. Is a native of Germany.

[10] VERONICA *Longifolia.*

*Long-leaved Veronica.*] Grows two feet high, with ſpear-ſhaped, acute, ſerrated, ſhining-green leaves, placed oppoſite; and the ſtalks terminated by long ſpikes of blue flowers. Grows naturally in Italy.

All theſe plants are hardy herbaceous perennials, with fibrous roots of long duration, ſending up new ſtalks annually; arriving to full growth in May, June, and July, when they flower abundantly in ſpikes and cluſters as in their deſcriptions; each ſpike and cluſter compoſed of many ſeparate flowers, univerſally monopetalous, wheel-ſhaped, and divided into four parts, and ſucceeded by ripe ſeed in Auguſt and September.

They are all hardy enough to grow any where in a garden; but are generally the moſt proſperous in ſomewhat ſhady moiſt ſituations.

Their merit for garden culture is principally for variety and ornament to the common borders, &c. as flowery plants; and being arranged in concert with other hardy perennials, they will effect an agreeable diverſity in the ſummer time, when in flower.

Many of theſe plants are kept in the public nurſeries for ſale, and may be tranſplanted in autumn or ſpring in the gardens, where they will flower annually, and encreaſe conſiderably by the roots.

They

They are propagated by parting the roots, and by ſeed.

By parting the Roots.—This may be effected either in autumn or ſpring, by taking up the plant and dividing the roots into ſeperate ſlips, not too ſmall; and planted either where they are to remain, or in the nurſery for a year, or till wanted.

By Seed.—Sow it in autumn or in ſpring in any bed or border, and raked in; and when the plants are come up and a little advanced in growth, plant them out either to remain or in the nurſery.

VERTICILLUS, a Whorl.

A mode of flowering, in which the flowers are placed in whirls or rings round the joints of the ſtalk as in baum, ſage, hyſſop, &c.

VIBURNUM.

Wayfaring Tree, Gelder Roſe, Lauruſtinus, &c.

This genus exhibits a collection of elegant deciduous and evergreen flowering ſhrubs, great ornaments to the ſhrubbery and other hardy plantations, riſing with upright branchy ſtems, ſome fifteen or twenty feet high, others not half ſo much; adorned with heart-ſhaped, roundiſh, lobated, and oval leaves in the different ſpecies; and numerous ſmall bell-ſhaped, five-parted flowers in large umbellate cluſters at the termination of the branches, appearing very ornamental.

Claſs and order, *Pentandria Trigynia.*

*Characters.*] CALIX is ſmall, five parted, and permanent.—COROLLA is ſmall, monopetalous, bell-ſhaped, and divided into five obtuſe reflexed ſegments.—STAMINA, five awl-ſhaped filaments, with roundiſh antheræ.—PISTILLUM, a roundiſh germen under the corolla, no ſtyle, but a turbinated gland inſtead of it, and three ſtigmas.—PERICARPIUM, a roundiſh unilocular berry, with one roundiſh hard ſeed.

To this genus is added the *Opulus* or *Gelder Roſe*, and the *Tinus* or *Laurus Tinus*; conſiſting in the whole of eight or nine ſpecies, all of the hardy tree and ſhrub kind, ſix or ſeven of which being of the deciduous kind, and one is an evergreen.

*Deciduous Kinds.*

Under this head is compriſed the common *Viburnum*, *Opulus* or *Marſh Elder*, and *Gelder Roſe*, and four or five other ſpecies, all of the deciduous kind, or ſuch as ſhed their leaves in winter; ſome are of Engliſh growth, others from America, and garniſhed moſtly with large, heart-ſhaped, round, and lobated leaves, and numerous ſmall white flowers, collected in cymoſe umbels at the ends of the branches, as in their deſcription.

[1] VIBURNUM *Lantana.*

*Lantana, Common Viburnum, Wayfaring, or Pliant Mealy Tree.*] Riſes with a woody ſtem, branching twenty feet high, having very pliant ſhoots covered with a lightiſh-brown bark; large heart-ſhaped, veined, ſerrated leaves, white and hoary underneath; and the branches terminated by umbels of white flowers, ſucceeded by bunches of red berries. Grows naturally in England in hedges, &c.

*Varieties.*] Striped-leaved—Oval-leaved.

[2] VIBURNUM *Opulus.*

*Opulus or Gelder Roſe.*] Conſiſting of the two following varieties, one with flat-flowers, the other globular, viz.

*Gelder Roſe with flat Flowers, or Marſh Elder.*] Grows eighteen or twenty feet high, branching oppoſite, of an irregular growth, and covered with a whitiſh bark; large lobated or three-lobed leaves on glanduloſe foot-ſtalks, and large flat umbels of white flowers at the ends of the branches, ſucceeded by red berries. Grows naturally in England in marſhy places.

*Common Gelder Roſe, with a Globular Umbel (Roſeum).*] Grows fifteen or eighteen feet high, branching like the other, garniſhed with large lobated or three-lobed leaves, on glandular foot-ſtalks; and large globular umbels of white flowers at the ends of the branches, in great abundance.

*Variety.*] Variegated-leaved.

This tree when in bloom exhibits a ſingularly fine appearance, the flowers, though ſmall, are collected numerouſly into large globular umbels round like a ball; hence, it is ſometimes called Snowball-tree.

[3] VIBURNUM *Prunifolium.*

*Plum-leaved American Viburnum.*] Grows ten or twelve feet high, covered with brown and reddiſh bark; roundiſh, crenated, ſerrated, ſmooth leaves; and the branches terminated by umbels of white flowers, ſucceeded by dark red berries, rarely ripening in England.

[4] VIBURNUM *Acerifolium.*

*Maple-leaved Virginian Viburnum*] Grows eight or ten feet high; lobated leaves cut into three principal lobes, growing on ſmooth foot-ſtalks; and white flowers in umbels along the

the ſides of the branches, rarely ſucceeded by berries in England.

[4] VIBURNUM *dentatum.*

*Dentated Virginia Viburnum.*] Grows eight or ten feet high, having a ſmooth light bark; oval, dentated-ſerrated, plicated leaves; and large round bunches of white flowers at the ends of the branches, rarely ſucceeded by berries in England.

[5] VIBURNUM *nudum.*

*Naked-umbelled, or Lauruſtinus-leaved American Viburnum.*] Grows ten or twelve feet high, very branchy on every ſide to the bottom, covered with a reddiſh or purple bark; large, oval, ſpear-ſhaped, wholly entire leaves, of a ſhining green colour; and the branches terminated by umbels of white flowers, reſembling thoſe of the common *Lauruſtinus*, not ſucceeded by berries in England.

*Varities.*] Deciduous-leaved— Evergreen-leaved.

[6] VIBURNUM *Caſſinoides.*

*Caſſinoides, Baſtard Caſſine, or Caſſioberry Buſh.*] Grows eight or ten feet high, branching numerouſly, aſſuming a buſhy growth; ſmall, oval-oblong, crenated, ſmooth leaves placed oppoſite on foot-ſtalks, having keel-ſhaped glands, and ſmall umbels of white flowers at the ſides of the branches; is a native of Virginia and Carolina.

All theſe deciduous *Viburnums* come out into leaf in April and May, and commonly flower in June and July, the flowers ſmall, but collected numerouſly into cymoſe umbels; are very conſpicuous, ſucceeded by large bunches of red berries in autumn; though ſeldom any but thoſe of the *Lantana* and *Opulus* attain perfection in England.

*Evergreen Kinds.*

Under this head is compriſed only one ſpecies *(Common Lauruſtinus)* a well known old inhabitant of our gardens, furniſhing ſeveral beautiful varieties, valuable both as fine, hardy evergreens, and elegant flowering ſhrubs, remarkable for exhibting their flowers in winter and early ſpring in defiance of the ſevereſt cold.

[7] VIBURNUM *Tinus.*

*Common Lauruſtinus, or Evergreen Viburnum.*] Grows eight or ten feet high or more, branching numerouſly from the bottom upward, aſſuming a cloſe buſhy growth, with the branches ſomewhat hairy and glandulous; very cloſely garniſhed with oval, wholly entire leaves of a ſtrong green colour, placed in pairs oppoſite; and whitiſh and red flowers, collected numerouſly in large umbellate cluſters all over the plant, at the ſides and ends of the branches, from January until March or April, exhibiting a moſt beautiful appearance.

*Varieties.*] Narrow-leaved — Broad-leaved — Shining-leaved — Hairy-leaved— White ſtriped-leaved — Yellow ſtriped leaved; all of which are of ſhrubby, buſhy growth, cloſely garniſhed with leaves all the year, and produce a great profuſion of umbellate flowers in winter and ſpring, as before mentioned.

All theſe different ſpecies of *Viburnum*, both deciduous and evergreen kinds, being of the tree and ſhrub kind, are woody and durable in root, ſtem, and branches; the firſt ſeven ſorts are deciduous, and the eighth is an evergreen, and are all of ſuch hardy temperature, as to grow freely in the open ground all the year, in ſhrubberies, and other hardy plantations; though the *Viburnum Caſſinoides* is rather ſomewhat tender in winter, whilſt young, but may be gradually hardened to bear all weathers like the other ſorts, eſpecially if planted in a ſheltered ſituation; but as it is ſometimes liable to ſuffer in very ſevere winters, it is alſo adviſeable to keep ſome in pots to move under ſhelter occaſionally in ſevere weather; however, all the other ſorts, both deciduous and evergreen kinds, will ſucceed any where at all ſeaſons without trouble.

With reſpect to their uſes for garden-culture, they all demand attention as furniture to diverſify the ſhrubbery, and alſo other ornamental plantations of the tree and ſhrub kind; all of which may be procured at the public nurſeries, at a moderate price, and may be tranſplanted almoſt in any open weather from October till March.

In their arrangement in the ſhrubbery, the deciduous ſorts ſhould be diſpoſed principally with others of that tribe, and the *Lauruſtinuſes*, chiefly in the evergreen clumps, &c. though ſome diſtributed thinly towards the fronts of the deciduous compartments, will exhibit a lively variety in winter and ſpring; ſuffering the whole, both deciduous and evergreens to aſſume nearly their own natural growth, except juſt retrenching occaſional lower ſtragglers from the ſtem, and long, irregular, rambling ſhoots of the head.

But the *Lauruſtinuſes* are alſo often employed to plant againſt unſightly walls, or other diſagreeable fences in fore-courts, and other compartments near the main dwelling, &c. to hide their deformity from ſight, by their perpetual verdue, and where they will alſo flower profuſely, and have a very ornamental effect.

Sometimes alſo the Lauruſtinus is planted as detached objects in borders and capacious, ſpaces of graſs ground, and there ſometimes trained to a ſingle ſtem, a foot or two high, and encouraged to branch out into a cloſe buſhy round head: in which it has a pretty effect, both as an evergreen and flowering ſhrub

*Method of Propagation.*

Many of the ſorts may be propagated by ſeeds; all of them by layers, and many of them alſo by cuttings.

By Seeds.—Moſt of the deciduous kinds may be raiſed abundantly from ſeeds in the open ground; ſome of them producing plenty of berries in England, others not, and thoſe of moſt of the ſorts may be had of the ſeedſmen; all of which may be ſowed in autumn or ſpring, in beds of common earth, and covered an inch deep; they will come up, ſome the firſt year, others not till the ſecond; and when the plants are a year or two old, plant them out in nurſery rows to remain till wanted.

By Layers.—All the ſorts, both deciduous and evergreen kinds, grow freely by layers, which is the moſt expeditious mode of propagating them, and may be effected in autumn, winter, or ſpring, though the ſooner the better; chuſing for this purpoſe the young lower branches, lay them and peg them down in the earth in the common way; they will all readily emit roots in ſpring and ſummer, fit for tranſplanting next autumn.

By Cuttings. — Moſt of the deciduous kinds, particularly, grow tolerably well by cuttings; though all the ſorts both deciduous and evergreen kinds may be tried by this method; it is ſoon done, and autumn is the proper ſeaſon; chuſing cuttings of the robuſt young ſhoots, cut into moderate lengths, and plant them in any moiſt border in rows, many of them will root and ſhoot at top next ſummer, and form tolerable little plants the ſame year.

VICIA.

Vetch or Tare, including alſo the Faba or Bean.

They are hardy herbaceous annuals and perennials, principally for œconomical purpoſes, as the common Vetch for fodder to cattle, and the ſeeds for poultry, &c. and the Bean, both as a fine ſummer eſculent for the table, to eat when green and young, and when dry to feed horſes and hogs, &c. though ſome ſorts, alſo both of the Vetch and Bean kinds, are proper to diverſify the compartments of the pleaſure-ground; all of which are of the fibrous-rooted tribe, and moſtly riſe with annual ſtalks, ſome long and trailing as in moſt of the Vetch kinds; others erect, as in all the Bean tribe; garniſhed moſtly with pinnated leaves of ſeveral pair of lobes, and papilionaceous flowers along the ſides of the branches.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, tubulous, and five-parted at top.—COROLLA, is papilionaceous, with an oval, broad vexillum, reflexed on the ſides, two almoſt heart-ſhaped wings, and ſhort keel, with an oblong, two-parted claw or tail.—STAMINA, ten diadelphous filaments, having roundiſh, four-furrowed, erect antheræ.—PISTILLUM, a long, narrow, compreſſed germen, filiforme ſtyle, and obtuſe ſtigma, bearded underneath. —PERICARPIUM, a long, leathery, bivalvular pod of one cell, containing ſeveral roundiſh and compreſſed ſeeds.

There are about eighteen ſpecies of *Vicia*, moſtly of the Vetch Tribe, and only one ſpecies of the Bean, which comprehends many varieties.

*Vetch Kinds.*

There are many ſpecies of the Vetch, though only a few of them have merit for general culture; ſome to cultivate in the fields to cut green for fodder, and to ſtand to ripen ſeed, (Tares) to feed pigeons and other poultry, hogs, &c. and ſome to cultivate in gardens for variety; conſiſting of annuals, biennials, and perennials, moſtly with long, ſomewhat trailing, or climbing ſtalks, and ſome erect; all garniſhed with pinnated leaves of many pair of ſmall lobes, terminated moſtly by cirrhi or tendrils for climbing; and flowers generally from the ſides of the branches, either ſingly or by twos, or many together on each peduncle, in

in ſpikes, &c. ſucceeded by oblong pods filled with ſmall roundiſh ſeeds.

The moſt remarkable ſpecies for uſe or variety are,

[1] VICIA *Sativa. (Annual.)*

*Common cultivated Vetch or Tare.*] Riſes with weak, angular, ſtreaked, declinating ſtalks two or three feet long, garniſhed with pinnated leaves of ſeven or eight pair of oblong blunt lobes, and ſpotted ſtipula; and purple flowers generally two together, ſucceeded by erect pods in pairs, containing a few round ſeeds.

*Varieties.*] Common purple-flowered as above — White-flowered — Early ſummer Vetch—Black-ſeeded—White-ſeeded, &c.

This ſpecies is the ſort of Vetch or Tare that is commonly cultivated in fields, to cut green for ſummer fodder, which is excellent feed for horſes, &c. and ſome alſo to ſtand to bring forth ſeeds for the uſes before hinted.

[2] VICIA *Biennia. (Biennial.)*

*Biennial multiflorous Siberian Vetch.*] Grows five or ſix feet long, having large pinnated leaves of ten or twelve or more ſpear-ſhaped, ſmooth lobes on furrowed foot-ſtalks, and each peduncle having many light-blue flowers, ariſing at the ſides of the branches, ſucceeded by ſhort compreſſed pods.

[3] VICIA *Sylvatica. (Perennial.)*

*Wood multiflorous Vetch.*] Riſes with cirrhoſe, climbing ſtalks, five or ſix feet long; pinnated leaves of ſeven or eight pair of oval lobes, and denticulated ſtipula, and each peduncle ſupporting many pale-blue flowers; grows wild in England, &c. in woods and among buſhes and hedges.

[4] VICIA *Cracca.*

*Cracca or Tufted Vetch.*] Riſes with climbing ſtalks five or ſix feet long; pinnated leaves of ten pair of ſpear-ſhaped, hairy lobes, and entire ſtipula; and peduncles ſupporting each many blue imbricated flowers. Is a native of England and moſt parts of Europe.

[5] VICIA *Caſſubica.*

*Caſſubian Ligneous Vetch.*] Hath trailing ſtalks two or three feet long, becoming ſomewhat ligneous; pinnated leaves of eight or ten pair of oval, acute, lobes, and entire ſtipula; and each peduncle having about ſix pale-blue flowers. Is a native of Germany.

The above five ſpecies are the moſt noted ſorts of the Vetch or Tare kind, ſome of which being in great eſtimation for field culture, to produce green fodder as before noticed; but the firſt ſort, in particular, having the moſt ſucculent ſtalks, are in moſt eſteem for general culture, being generally cut whilſt the ſtalks are green and tender, till they come into flower in June and July.

They are alſo ſometimes introduced into gardens, as climbers, for variety, eſpecially to diverſify wood-walks, thickets, &c. to climb upon the ſhrubs and buſhes; ſowing the ſeed in the places where the plants are deſigned to remain, and they will readily come up and flower ornamentally in ſummer. See their *Propagation* below.

As all the ſorts riſe with long weak ſtalks, ſomewhat reſembling the pea tribe, they either trail on the ground or climb upon any adjacent ſupport, or upon one another, by means of their cirrhi or claſpers, at the termination of the leaves; and by which they mount upon buſhes or hedges, &c. ſeveral feet high, ſhooting up into ſtalk in ſpring, and flower in June or July; all producing papilionaceous or butterfly-ſhaped flowers, ſome but two on each peduncle, and ſome many as before obſerved, ſucceeded by longiſh pods of the leguminous kind, containing round ſeeds, ripening in autumn.

*Method of Propagation, &c.*

All the ſorts are eaſily propagated by ſeeds, ſowed principally where the plants are to remain in autumn or ſpring, both for field-culture and in gardens.

For Field Culture.—They are ſowed both in autumn or ſpring occaſionally: when intended to raiſe a crop to cut for early fodder, they are often ſowed in autumn, about Auguſt or early in September; in order that they may come up ſoon after the ſame year, and afford an early cutting next ſummer; though they may alſo be ſowed in ſpring both for fodder and to ſtand to produce ſeed or Tares; remarking, however, the ſummer Vetch in particular, being ſomewhat tender, ſhould never be ſowed till the ſpring; obſerving in ſowing the different ſorts, that the common allowance of ſeed is generally about two buſhels to an acre, which may either be ſowed broad-caſt and ploughed or harrowed in, or in drills, two or three feet aſunder, and earthed over an inch or two deep: that by ſowing them in drills, the ground can be readily hoed between by horſe or hand hoeing, to kill weeds, and land up the plants, as practiſed for peas.

For Garden Culture.—When intended to cultivate any of theſe plants in gardens for variety; ſow the ſeeds in autumn or ſpring in the borders of ſhrubberies, wood-walks, wilderneſſes, thickets, &c. in the places where they are to remain, in patches near the ſhrubs and buſhes to climb thereon, or in open ſpaces to climb upon ſticks.

*Faba or Bean Kinds.*

To this genus *Vicia*, is now added the article *Faba* or Bean, formerly conſidered as a diſtinct genus; but its general characters proving the ſame as the Vetch, the botaniſts have lately ranged it as a ſpecies of that family, by the name of *Vicia Faba*; conſiſting of but one ſpecies only, which, however, compriſes numerous varieties, and is ſuppoſed the Common Field or Horſe Bean is the original ſort, and parent of all the other varieties commonly called Garden Beans.

VICIA *Faba.* (*Annual.*)

*Faba or Bean.*] Hath fibrous roots, upright, thick, ſucculent, firm ſtems, riſing from one or two to four feet high or more; garniſhed with large winged ſucculent leaves of two or three pair of large lobes, without cirrhi or claſpers; and numerous papilionaceous flowers all along the ſides of the ſtalk, ſucceeded by long, compreſſed pods, containing the Beans.

It is a hardy herbaceous annual, and ſaid to be originally a native of Ægypt; but all the varieties have been long inhabitants of our gardens, and grow freely any where in the open ground.

*Varieties.*] There are numerous ſorts of Beans, all varieties of the ſame ſpecies (*Vicia Faba*) for their general growth and ſtructure, foliage, flowering, fruiting, &c. are exactly the ſame, and only vary more or leſs from one another in their ſize of growth, ſize of the leaves, pods, and Beans, times of attaining perfection, domeſtic properties, &c. for all the different varieties are ſubject to vary exceedingly; and as in the Common Field or Horſe Bean, we ſhall often find ſome among them that vary conſiderably from the original, both in ſubſtance of ſtalk and pods; and from theſe variations the different varieties of Garden Bean were firſt obtained, and by degrees improved by culture to their preſent ſtate of perfection; all of which are alſo very apt to vary from one to the other, unleſs ſome attention is obſerved in ſaving the ſeed Beans from the beſt plants of the reſpective varieties; conſiſting of the following ſorts, arranged under three heads, according to their growth and times of attaining perfection, viz. Small early kinds.—Middling kinds.—And large late kinds.

*Small Early Kinds.*

Thoſe under this head are of the loweſt growth, riſing only from about a foot and half to two and a half high, and ſome that ſcarely obtain a foot ſtature; but all very great bearers with ſmall pods and Beans, and are valued for arriving earlier to perfection than any other ſorts; and are therefore proper to plant on warm borders in autumn and winter for the early crops to gather in the middle or end of May, and in June.

*Early Mazagan Bean.*] Grows but half a yard or two feet high, with ſlender ſtalks fully loaded from bottom to top with very ſmall pods, arriving to perfection in May or beginning of June.

This is the ſmalleſt and earlieſt of all the tribe of Beans.

*Early Portugal or Liſbon Bean.*] Grows two feet high or more, with ſomewhat ſtronger ſtalks and larger pods than the Mazagan Bean, arriving to perfection a few days after that ſort.

*Small Spaniſh Bean.*] Grows ſtronger than the two former, with ſomewhat larger pods and Beans, arriving to perfection ſoon after the Portugal Bean.

*Dwarf Fan or Cluſter Bean.*] Grows low, with ſeveral ſpreading ſtems from ſix to ten or twelve inches high, very fully loaded with ſmall pods.

This is chiefly planted for variety or curioſity.

Moſt of theſe ſmall Beans if gathered while young, eat very ſweet and palatable; particularly the firſt three ſorts, but if ſuffered to attain full growth, or become the leaſt black-eyed, they eat dry, coarſe, and of a diſagreeable reliſh.

Theſe kinds have merit principally to plant for the earlieſt crops, and the firſt two or three ſorts, are the moſt eligible for that purpoſe; but the Mazagan kind is the earlieſt of all, proper to plant for the firſt crop, and the Portugal and Small Spaniſh Bean next; all of which are proper for planting early on warm ſouth borders, or other ſheltered ſunny expoſures, under or near walls, pales, or hedges, every month from October till December or January; in order that if the

the firſt planting ſhould fail by inclement weather in winter, the others may ſucceed; and if all the crops ſhould ſurvive the froſt, they will ſucceed one another regularly in bearing; planting them in rows, ranging ſouth and north two feet and a half aſunder, an inch and half deep, and two or three inches apart in each row; likewiſe may plant one row length-ways cloſe along under the wall, &c.

But as to the Dwarf Bean, it is not proper to be planted for any general crop, only a few for variety; and for which purpoſe it may be planted either in autumn or winter, or in any of the ſpring or ſummer months till June or July, in rows two feet aſunder, or in patches about the borders.

*Middle Size Later Beans.*

Theſe ſorts are of ſtronger and taller growth than thoſe of the former claſs; they riſing with ſtalks from two feet and half to a yard or more high, producing longiſh, middle-ſized pods of different lengths and thickneſs in the different ſorts; being proper to plant for the firſt main crops, any time from November or December till February or March, to ſucceed the ſmall early Beans, and will arrive to perfection for the table in June and July.

*Long Podded Bean.*] Riſes with ſtronger ſtems, a yard or more high; a remarkable great bearer, producing very long, narrowiſh pods cloſely filled with oblong, middle-ſize Beans.

*Varieties of this are.*—Early long-podded Bean. —Tall long-podded Bean. — Turkey long-podded Bean, riſing with ſtronger ſtalks producing the largeſt pods and Beans.

All theſe long-podded Beans are remarkable great bearers, very profitable for a family and market, and if gathered for uſe while they are moderately young, they will eat tolerably ſweet and well flavoured.

*Broad Spaniſh Bean.*] Grows moderately ſtrong, a yard or more high, producing broadiſh pods and Beans; is a very good bearer, and the Beans boil tender and well flavoured.

*White-bloſſomed Bean.*] Grows two feet and half high, producing entire white flowers, and great abundance of ſmalliſh, long, narrow pods, filled with oblong Beans.

This is a good bearer and an excellent table Bean, remarkable for boiling green and tender.

*Red-bloſſomed Bean.*] Riſes with firm ſtalks two feet and half high, producing entire red bloſſoms, ſucceeded by ſmalliſh pods and Beans, not near ſo palatable to eat as the white bloſſom kind.

Other leſs material varieties of middle-ſize Beans are Nonpareil Bean — Mumford Bean, —Black-bloſſom Bean. — Green Venetian Bean.

Remark, that of the above varieties of Bean ranged in this claſs, the firſt three ſorts, Long Pods, Broad Spaniſh, and the White-bloſſomed Bean, are the beſt for general culture; though ſome of all the others may alſo be planted occaſionally for variety and experiment; and the ſeaſon for planting all the ſorts is, that for the firſt crop may plant in November or December on ſome broad warm border, or in any of the moſt ſheltered kitchen-garden quarters, in rows a yard aſunder; repeating the planting every month till March in the open quarters or in fields, &c. after that if a longer ſucceſſion of thoſe ſorts is required, plant ſome every three weeks in an open expoſure, till May or June.

*Larger Late Kinds, commonly called Broad Beans.*

Theſe are the ſtrongeſt growers of all of the kinds; they riſe with thick ſtems three feet and half high or more, producing large broad pods with Beans proportionably large; and are ſuperior to all the others to plant for the general crops, to ſucceed the long pods, and others of that claſs; being proper to plant principally in the ſpring, or at leaſt not earlier than December or January, for the firſt crop; and for the general crops, ſhoud be planted every month or three weeks, from January or February, until May; and they will arrive to perfection in July and Auguſt, and are all moſt excellent family beans, and always the moſt ſaleable in market.

*Sandwich Bean.*—Grows three feet and a half high, or more, producing large, broad pods, and oblong broadiſh Beans; and bears abundantly.

*Toker Bean.*—Grows ſtrong, three feet and a half high, or more, producing long broadiſh pods, and large oblongiſh Beans, and the plants bear very plenteouſly.

*Windſor Bean.*——Riſes with very large, ſtrong ſtems, three or four feet high, bearing very large, broad pods, having very large

large, roundiſh Beans, the largeſt of all the Bean tribe, and the moſt excellent for eating.

Of this claſs of large Beans, the Sandwich and Toker kinds, being of leſs ſucculent growth than the Windſor, are rather hardier, and may be planted earlier, that is, before Chriſtmas, for the firſt crop; and any time till April or May, if required; but the Windſor may alſo be planted any time in January and February, in open weather; and thence every three or four weeks, till the end of April, for the main crops; or may continue planting them till the end of May, to continue the ſucceſſion of theſe kinds for the table as long in the ſeaſon as poſſible.

All of which large kinds of Beans ſhould be planted in open expoſures in gardens and fields; the firſt plantings before or ſoon after Chriſtmas may be in the moſt ſheltered, dry ſituation; after that the ſucceſſion crops may be planted in any open place, generally planting them by dibble in rows, a yard aſunder, or three feet and a half for the large Windſor Beans, four or five inches aſunder in each row, and three inches deep.

*General Obſervations.*

All the varieties of Bean in the above three claſſes, are hardy, herbaceous annuals, that will grow in any common ſoil of a garden, and in the open fields; are all raiſed annually from ſeed, planted at ſeveral different times, from October till May, in order to obtain a ſucceſſion of young green Beans for the table three or four months in ſummer; for by planting early and late kinds every month, from October or November until March; and every three weeks or fortnight, from Mareh till May, June, or July, a conſtant ſucceſſion of young Beans is obtained from the latter end of May until September, or beginning of October; though as to the general planting ſeaſon, that after having planted a few of each ſort before Chriſtmas, to come in early, the main crops are plant d in January, February, March, and Apr; and the general ſeaſon of Beans in full p- fection of bearing and goodneſs, is Jun, July, and Auguſt.

As therefore the utility of Garden-Beans, both for private uſe, and ſupply of the markets, is very conſiderable for about three months in ſummer, a principal ſhare of kitchen-garden ground and field-land ſhould be allotted annually for the culture of ſeveral different crops, ſucceeding one another in bearing in regular ſucceſſion from May or June till Auguſt or September, as before obſerved.

They will all grow freely in any common fertile ſoil, in a garden or field, but ſhould be allowed always an open, free ſituation, not much overſpread with trees, &c. which would draw them up weak and tal, without yielding any conſiderable produce; generally allowing the warmeſt ſituations for the early crops before Chriſtmas; but the ſucceeding ones may after that time be planted in any open expoſure; and for the late plantings in May and June, &c. ſhould generally chuſe the moiſteſt ſtrong land.

As to the general method of planting and and culture: all the ſorts muſt be planted in rows, the diſtance before mentioned, according to the ſize of the Beans, planted either by dibble, or laid in drills; or for early planting in dry ground, may firſt draw ſhallow drills, then plant the Beans in a row along the bottom; allowing from two to four or five inches diſtance in the row, and from one and a half to three inches deep; and when the plants are come up two or three inches high, land them up on each ſide of the row with a drawing hoe; and after having advanced nearly to full growth and in bloom, it is proper to top the plants in general, which throws all the nouriſhment to the embryo pods, and greatly promotes their ſetting, and forwards their growth; and in the latter crops prevents their being ſo much anoyed with the ſmall black fly.

## VINCA.

*Pervinca*, or Periwinkle.

This genus is compoſed of ſhrubby evergreen trailers and upright growers, for the ſhrubbery and ſtove collections, having all durable ſtems, and branches adorned with oval, oblong, and ſpear-ſhaped, ever-green leaves; and monopetalous, ſalver-ſhaped, five-parted flowers, at the axillas of the ſtalk branches.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is divided into five parts, and permanent.—COROLLA, is monopetalous, and hypocrateriform, or ſalver-ſhaped, tubular below wirh a horizontal, broad-ſpreading brim, cut into five obtuſe ſegments.—STAMINA, five ſhort inflexed filaments, having obtuſe, erect, membranaceous antheræ.—PISTILLUM, two roundiſh germens,

germens, terminating in one cylindric ſtyle, larger than the ſtamina, having two ſtigmas, one orbicular, and the other headed, and concave.—PERICARPIUM, two long, taper, erect follicules, of one longitudinal valve, containing many oblong, cylindric ſeeds.

There are four ſpecies of *Vinca*, three of them common to the Engliſh gardens, two of which are hardy, trailing, and declinated plants for the ſhrubbery; the other is an upright, tender ſhrub for the ſtove collection; and are all of the ever-green tribe.

*Hardy Kinds.*

Theſe have ſlender ſtalks, ſome that trail and extend along the ground, branching numerouſly, and cover the ſurface; others grow more erect, with declinated branches; and conſiſt of two ſpecies, both evergreens, and natives of England, &c. growing wild, under buſhes, hedges, and in woods; but are introduced into moſt of our eminent ſhrubberies, to plant as trailers in particular departments, between ſhrubs, to overſpread the ground, and occaſionally to mount erect upon ſupport, and form a buſhy growth.

[1] VINCA *Minor.*

*Minor or ſmaller Periwinkle.*] Hath ſlender, ligneous, trailing, green ſtalks, branching and running conſiderably along the ground, emitting roots at the joints; garniſhed with oval, ſpear-ſhaped, thick, ſmooth, ſhining-green leaves, in pairs oppoſite; and flowers growing ſingly on proper peduncles, at the ſides of the branches, of different colours in the varieties.

*Varieties are.*] Common green Periwinkle with blue flowers—With white flowers—Double blue flowers—Double white flowers—Double purple flowers—Yellow-ſtriped-leaved, with flowers of all the above colours—White ſtriped-leaved, with flowers of different colours.

[2] VINCA *Major.*

*Major or Large Green Periwinkle.*] Riſes with ſhrubby, ſomewhat erect, green ſtalks, a foot or two high, with the tops inclining to the ground; large, oval, ſhining-green leaves, in pairs oppoſite; and large blue flowers ſingly on foot-ſtalks at the axillas of the branches.

*Variety.*] With white flowers.

Both the ſpecies are perennial in root, ſtem, and branches, with leaves in perpetual verdure, and begin flowering in the ſpring, about March and April; the flowers moderately large, each being of one ſalver-ſhaped petal, ſpreading at the brim, and cut into five parts; generally continue flowering in ſucceſſion ſeveral months, and even ſometimes in winter, in mild ſeaſons, eſpeciall the *Vinca Major*.

As both the ſpecies and their reſpective varieties are very hardy plants, that proſper under trees and buſhes, even in cloſe thickets, &c. and ſpread and cover the ground; they are proper to plant towards the fronts or verges of ſhrubbery clumps, wilderneſſes, and thickets, between the trees and ſhrubs, next the walks, and on the ſides of ſhady banks, &c. diſpoſed, ſome to over-run the ſurfaee between the ſhrubs, in particular places contiguous to ſhady walks, &c. others in patches, to run and entangle with one another in tufts; and ſome planted entirely detached, particularly the *Vinca Major*; and ſupported with ſtakes, and trained with an erect ſtem a little height, and encouraged to branch out above into a buſhy head; in all of which modes, diſtributing them in the ſeveral plantations, they will encreaſe faſt in growth, and effect a very pretty variety at all ſeaſons of the year.

They are all expeditiouſly propagated by layers, cuttings, and ſuckers.

By Layers.—Their trailing branches being layed in the ground any how, at almoſt any ſeaſon, they will moſt readily take root; and thoſe of the *Vinca Minor* particularly, multiply exceedingly without care; for the trailing ſtalks root in the ground at every joint as they extend along, furniſhing numbers of good-rooted plants in one ſummer, fit to plant off in autumn.

By Cuttings.—All the ſorts will alſo readily grow by cuttings of the ſtalks and branches, planted in autumn or ſpring, in a ſhady border, and they will be well rooted by the following autumn.

By Suckers.—They naturally ſend up ſuckers from the root in ſummer, which may be taken up with roots any time in open weather, from autumn till ſpring, and planted where they are to remain.

*Tender Stove Kind,*

Conſiſts of one ſhrubby ſpecies, a native of Madagaſcar, and is retained here in ſtoves, as an elegant evergreen, and beautiful flowering ſhrub.

[3] VINCA *roſea.*

*Roſe*

*Roſe Periwinkle of Madagaſcar.*] Riſes with an upright, ſhrubby, ſmooth, branching ſtem a yard or more high; having a browniſh bark; oblong-oval, ſmooth, firm leaves, placed oppoſite; and large beautiful, roſe-like, crimſon, and pale-red flowers, ſingly and in pairs at the ſides of the branches being large, ſpreading above and divided into five ſegments; appearing very ornamentally from ſpring till winter, ſucceeded by ripe ſeeds in the autumn.

This elegant little ſhrub being an inhabitant of the hot parts of Africa, in this country muſt always be kept in pots, in order to be retained in the ſtove; in which it will flower annually in great abundance, managing it as directed for other ſhrubby exotics of the ſtove. See STOVE PLANTS.

It is propagated by ſeed and cuttings, aſſiſted by a hot-bed.

By Seed.—Sow it in the ſpring in a pot of light rich earth, half an inch deep, and plunge the pot in a hot-bed or in the bark-bed in the ſtove; and when the plants are come up about three inches high, prick them ſeparately in ſmall pots and plunged again in a hot bed, &c. giving occaſional ſhades from the ſun, and proper waterings; and as they advance in growth ſhift them into larger pots and keep them always in the ſtove.

By Cuttings.—In ſpring or ſummer take off ſome cuttings of the young ſhoots, plant them in pots; and plunge them in any hot-bed or in the bark-bed, and they will root the ſame year fit to pot off ſeparately, and managed as directed for the ſeedling plants.

## VIOLA.

Violet.

There are many ſpecies of Violets, moſtly very low, herbaceous, fibrous-rooted perennials and annuals, ſome conſidered as flowery plants to adorn the fronts of borders, others for variety and medical purpoſes, riſing with cluſters of leaves and ſhoots but a few inches high, and low ſtalks the ſame height, crowned with ſmall, irregular, pentapetalous flowers.

Claſs and order, *Syngeneſia Monogamia.*

*Characters.*] CALIX is pentaphyllous, with the leaves oval-oblong, ſharp at top and obtuſe at the baſe; differently arranged in the different ſpecies, and perſiſtent.— COROLLA, is irregularly formed of five unequal petals, the upper one is broadeſt, obtuſe, and emarginated, having a corniculated or horned nectarium at the baſe; the two ſide-petals equal, obtuſe, and oppoſite, and the lower ones larger and reflexed upward.— STAMINA, five ſmall filaments, two of them placed at the upper petal, entering the nectarium by their annexed appendages; and obtuſe antheræ that generally coaleſce or connect.—PISTILLUM, a roundiſh germen, ſlender ſtyle and oblique ſtigma.— PERICARPIUM, an oval, trigonous, obtuſe, trivalvous capſule of one cell, containing many oval ſeeds.

There are more than twenty ſpecies of Violets, moſtly very low, herbaceous plants; many of them natives of England, and other different parts of Europe, and of America; and but only a few of them have merit as garden plants for ornament or variety, conſiſting of ſome perennials and an annual; comprehending the Common Violet, &c. Heart's Eaſe or Panſies.

### *Perennial Kinds.*

Conſiſt of the common odoriferous Violet and varieties, and three or four others of inferior value, all hardy perennials of humble growth.

1 VIOLA *Odorata.*

*Odoriferous or Common Sweet-ſcented March Violet.*] Hath a fibrous perennial root, ſending up a cluſter of heart-ſhaped leaves and ſmall, creeping, rooting ſhoots; and amongſt them riſe ſlender naked peduncles, three or four inches high, crowned with the flowers of different colours in the varieties, appearing in March.

*Varieties are.*] Common blue flowered—Pale-purple-flowered — White-flowered — Double blue-flowered—Double white-flowered.

The flowers of all the varieties impart a fine ſweet odour and are uſed in medicine; though the ſingle flowered kinds are the moſt odoriferous; but the double flowered varieties are largeſt and the moſt conſpicuous to ſight.

It grows naturally in woods, and under hedges, &c. in England and moſt parts of Europe, but has been a long reſident of gardens as a flowery plant, and for its flowers to uſe in medecine.

2 VIOLA *Hirta.*

*Hairy Inodorous Violet.*] Hath a fibrous, perennial,

perennial root, crowned with heart-ſhaped, hairy, hiſpid leaves; and amongſt them ſlender peduncles, a few inches high, terminated by larger blue flowers, like the common ſort, but without odour; grows wild in woods and hedges in England, &c.

[3]VIOLA *Palmata.*

*Palmated Virginia Violet.*] Hath a perennial root, crowned with five-lobed, palmated, or hand-ſhaped, indented leaves, and low peduncles, ſupporting white flowers in May or June.

[4]VIOLA *Montana.*

*Mountain upright Auſtrian Violet.*] Hath a perennial root; erect ſtalks a foot high; heart-ſhaped, oblong leaves; and purple flowers at the axillas of the branches; in April and May.

[5]VIOLA *Calcarata.*

*Calcarated Yellow Alpine Violet.*] Hath a perennial root, ſending up very ſhort ſtalks, four or five inches high, garniſhed with oblong, oval leaves: and ſlender peduncles, ſupporting yellow flowers ſtreaked with purple; having long ſpur or awl-ſhaped nectariums, longer than the petals; flowering moſt part of ſummer.

*Varieties.*] Common yellow purple-ſtreaked-flowered—Plain yellow-flowered—Purple-flowered.

Of the above five ſpecies of perennial Violets, the firſt ſort (*Viola ordorata*), is the moſt remarkable, being highly eſteemed for its ſweet-ſcented flowers; and is proper to plant on the verge of ſhrubberies, wood-walks, and in tufts or patches; and as to the other four ſpecies, although their flowers are without ſcent, they, if arranged in concert with the varieties of the common ſort, will effect an agreeable diverſity.

Though when the common Violet is intended to be cultivated for its flowers to gather, it may be planted in beds, or borders, alone; in rows, a foot aſunder, and they will ſoon encreaſe into large bunches.

They all flower in great abundance every year in their reſpective ſeaſons; the flowers are ſmall, irregular, and conſiſt each of five unequal petals; continuing in ſucceſſion three or four weeks, and are ſucceeded by ripe ſeeds in ſummer and autumn.

The propagation of all the ſorts is by parting the roots, and ſometimes by ſeed.

By Parting the Roots.—They all multiply by the roots; and the common Violet and the other creeping kinds propagate alſo abundantly by their repent ſhoots rooting in the earth; they may be parted or ſlipped in ſpring, ſummer, or autumn, as ſoon as they have done flowering, in moiſt weather, or early in ſpring; when each plant may be ſlipped, or divided into ſeveral ſlips, not too ſmall; and planted either at once to remain, or the weakeſt may be planted in nurſery-beds, to have ſummer's growth; and in either method each ſlip will ſoon encreaſe into a large tuft, and flower abundantly next year.

By Seed—Sow it either ſoon after it is ripe, or early in the ſpring, in a bed or border of light earth, and raked in; and when the plants are come up an inch or two high in ſummer, prick them out in a ſhady border, to grow till October, and then planted out finally to remain.

*Annual Kind.*

One ſpecies only come under this head; a well-known, little, tufty, very flowery plant, commonly called Heart's Eaſe, or Panſey; and is generally conſidered as an annual, becauſe it often periſhes the ſame year it is produced; yet it alſo ſometimes proves of a biennial or perennial nature, remaining in ſtalk and leaf all the year, in favourable ſeaſons.

[6]VIOLA *tricolor.*

*Violet tricolor, or three-coloured Violet, commonly called Heart's Eaſe, or Panſey.*] Hath a fibrous root, ſending up ſlender, triquetrous, or four-ſquare ſtalks, branching diffuſely, from ſix to ten or twelve inches high, aſſuming a buſhy, tufted growth; garniſhed with ſmall, oblong-oval, cut leaves; and at the axillas of the branches numerous variegated, tricoloured flowers, yellow, purple, and white; appearing in conſtant ſucceſſion all ſummer and autumn: grows naturally in cultivated places in the North of England, &c.

*Varieties.*] Low growing, with ſmall flowers.—Larger, upright, with large flowers.—Variegated, yellow, purple and white-flowered——Yellow-flowered, with purple ſpots—Purple, with yellow or white ſpots—White, with yellow and purple ſpots——Scentleſs flowered—Sweet-ſcented flowered.

All the varieties flower very profuſely, and variegated many different ways in the ſame

plant; and the moſt prevailing colours are yellow, purple, blue, and white; ſome of which being of a fine velvetty hue, particularly the purple; varying in different flowers; and all of which are ſucceeded by abundance of ſeed which ſoon ſcatters itſelf in the adjacent ground, and from which numbers of plants naturally riſe, without care of culture.

This elegant little plant merits culture in every garden, for the beauty and great variety of its tricoloured flowers; and it will ſucceed any where in the open borders, or other compartments, diſpoſed in patches towards the front; either by ſowing the ſeed at once to remain, or by putting in young plants previouſly raiſed in a ſeed-bed; they will begin flowering early in ſummer, and will continue ſhooting and flowering in ſucceſſion till winter; and even during part of that ſeaſon, in mild weather.

It is eaſily propagated by ſeed, ſowed either at once, where they are to remain, or for tranſplantation; and when once a few plants are raiſed, and have flowered and ripened ſeeds, they will naturally ſow themſelves, and produce a conſtant ſupply of plants.

However, the ſeaſon for ſowing them is in autumn and ſpring; the autumn ſowings come up the ſame year, ſtand the winter, and flower early in the ſpring following; and the ſpring-ſowed plants ſucceed them in flowering, and continue till winter. Sow them either in patches about the borders, half an inch deep, to remain; or in a bed or border, broad-caſt, and raked in; and when the plants are advanced two or three inches high, prick them out, to remain to flower, one or two plants in each patch, which will ſoon encreaſe into a large tuft.

VISCUM, Miſletoe.

An hardy, evergreen, paraſitical ſhrub, the branches are dichotomous, with obtuſe ſpear-ſhaped leaves, producing flowers growing in ſpikes and white glutinous berries.

Claſs and order, *Dioecia Tetrandria.*

*Characters.*] CALIX of the male flower is compoſed of four oval equal leaves.—COROLLA, none.—STAMINA, filaments, but form oblong pointed antheræ, each growing to a foliole of the calix.—The female flowers conſiſt of a CALIX, compoſed of four ſmall leaves, which are oval ſeſſile, deciduous, and ſitting on the germen.—COROLLA, none.—PISTILLUM, an oblong, three-cornered germen, ſituated under the receptacles with no ſtyle, having only an obtuſe ſtigma.—PERICARPIUM, a round ſmooth berry with one cell, containing a ſingle obcordated, obtuſe, carnoſe, and compreſſed ſeed.

We know but of one ſpecies.

VISCUM *Album, Miſſeltoe.*

Hath woody branches of a yellowiſh colour; they uſually grow in pairs, in a ſort of a forked manner, dividing from near the baſe of the main ſtem, and annually ſubdividing in a dichotomous form; at the joints of the diviſions grow the leaves, which are ſpear-ſhaped, obtuſe, of a thick conſiſtence and yellowiſh green, continuing all the winter; the flowers are produced in ſhort ſpikes from the wings of the branches, they are ſmall, and of a yellowiſh colour, they are ſucceeded by a large white viſcous tranſparent berry, which is ripe in the winter.

*Propagation.*

The propagation of this plant is by its ſeeds when the berries are full ripe; but as they will not grow by any means in the natural earth, being always found either on aſh, maple, apple, &c. trees, growing out of their branches, therefore to encreaſe them the following method ſhould be uſed: chuſe a fine ſmooth place of the tree, which you would wiſh them to grow upon; on the part thus choſen ſtick a few berries, their glutinous matter will affix them, though it would not be amiſs to cut the outer bark with a knife, and for a greater chance of ſucceſs, (as they do not always ſucceed), ſeveral branches of the ſame tree may be ſerved in the ſame manner. I have ſome reaſon to think that the ill ſucceſs which frequently attends the propagation of theſe plants by art is owing to the choice of the berries, for as they are of the dioecious claſs, bearing male and female flowers on different plants; the berries frequently gathered from male plants which not being near a female plant when in bloom may be deprived of the *farina fœcundans*, ſo neceſſary for vegetation; therefore in the choice of berries they ſhould be taken from female plants which grow near to thoſe of the other ſex.

The miſſeltoe is encreaſed in the woods chiefly by birds, particularly the thruſh, who in

in carrying the berries from tree to tree, and lodging ſome of them they adhere to the bark, and grow. This plant is ſaid to be poſſeſſed of many excellent virtues, and is uſed in nervous diſorders, &c.

VITEX. *Agnus Caſtus*, or Chaſte Tree.

Of this genus there is one hardy ſpecies cultivated in our ornamental gardens; theſe are ſhrubs furniſhed with digitated leaves and flowers growing in ſpikes.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX, a ſhort cylindrical monophyllous perianthium, indented in five parts.—COROLLA, a ringent petal, with a ſlender cylindric tube; the limb is bilabiated, both lips are divided into three ſegments, the middle one being broadeſt.—STAMINA, four capillary filaments, two of which are ſhorter than the others, having verſatile antheræ.—PISTILLUM, a roundiſh germen a ſlender ſtyle, and two awl-ſhaped ſtigmas.—PERICARPIUM, a globular berry of four cells, each containing a ſingle oval ſeed.

This tree was much celebrated among the ancients, on a ſuppoſition, that the influence of it was conducive to chaſtity (whence the name); but the moderns know of no ſuch peculiar virtue as has formerly been aſcribed to it.

This ſpecies is

VITEX, *Agnus Caſtus, the Chaſte-tree.*

Hath pliable branches, whoſe joints are long, riſing to the height of about five or ſix feet; they are of a browniſh grey colour, and are garniſhed with digitated leaves, compoſed of ſeveral folioles, which are narrow and of a dark green colour, and ending in obtuſe points; the flowers are produced at the ends of the branches in whorled ſpikes, which are pretty long, and of a bluiſh purple colour; they appear in autumn, but are not ſucceeded by ſeeds in this country.

A variety of this is called the broad-leaved *Agnus Caſtus*, the folioles of which are broader, ſhorter, and ſerrated; in other reſpects there is ſcarce any difference.

This ſpecies is eaſily propagated either by layers or cuttings any time in the winter, and when they have rooted may be taken up in the ſpring and tranſplanted.

VITIS, Vine.

A genus of well known deciduous climbers, of which there are ſeveral ſpecies, one of which hath many much eſteemed varieties; the other kinds are more noticed for their climbing property and ſingularity than the fruit which they produce.

Claſs and order, *Pentandria Monogynia.*

Characters.] CALIX, a very ſmall perianthium, indented in five parts.—COROLLA, five ſmall petals, which are deciduous.—STAMINA, five ſubulate, erect, patent-falling filaments, with ſimple antheræ.—PISTILLUM, an oval germen without a ſtyle, crowned with a blunt capitated ſtigma.—PERICARPIUM, a large roundiſh berry of one cell, containing five hard roundiſh ſeeds, narrowed at the baſe.

Species.

[1]VITIS *Vinifera.*

*Vine or grape.*] This hath lobate, ſinuated, naked leaves, with herbaceous flowers, growing in a racemus which becomes a bunch of red, white, black, &c. berries.

*Varieties of this ſpecies are.*] (1.) *July Grape*, this hath a berry, ſmall, round, and black, ſlightly growing on the branches, but very little eſteemed, excepting for its earlineſs; it ripens ſoon in Auguſt.—(2.) *Black Sweet-water*, hath roundiſh berries, growing compactly together in ſmall bunches; they ripen in Auguſt: the flavour being rich, and ſkin thin, invites the birds, flies, &c. to prey on them, which (in time) ſhould be guarded againſt.—(3.) *White Sweet-water*, this is an exceeding fine flavoured grape when perfectly grown, but the berries being liable to outgrow each other, makes the whole bunch incomplete; this ripens about the end of Auguſt.—(4.) *Muſcadine*, this is one of the fineſt white grapes which ripen againſt the common walls in this climate; the bunches are large, the berries are round, and of a very rich flavour; this will ripen in September.—(5.) *Black Cluſter Grape*, hath hoary leaves, the bunches are ſhort and very compact; the berries are ſmall, and ripen the end of September.

*The following Varieties will not well ripen in this Climate without the Aſſiſtance of Glaſs, &c.*

(6.) *Black Frontiniac*, hath ſhortiſh bunches, the berries of which grow pretty cloſe together; when ripe are round and of a deep black colour, covered with a mealy bloom; the flavour of this grape is very rich, of a muſcat taſte, and in very hot ſummers will ripen naturally in October.—(7.) *Red or grizly*

ly *Frontiniac*, hath middling ſized bunches, the berries are round, of a red colour, and ſtriped; this grape when thoroughly ripe, is of a moſt rich and excellent flavour; it rarely ripens in this climate without the aſſiſtance of heat.—(8.) *White Frontiniac*, this is a high flavoured grape, and hath a peculiar rich juice when perfectly ripe; the bunches are large, and the berries, which are round, are very cloſely joined to each other, whereby they are apt to rot each other before they are ripe, which in ſome meaſure is owing to the thinneſs of their ſkins; it is therefore neceſſary to thin them out when they are about the ſize of peas, whereby the ſun and air will have freer admittance, and thoſe which are left will be larger, more handſome, and higher flavoured; this grape will not ſucceed without artificial heat —(9.) *Muſcat of Alexandria*, hath long bunches, with oval large berries; there are two ſorts, one with white, and the other with red berries; they are a fine grape, but require a hot-houſe to perfect the fruit.—(10.) *Hamburgh Red and Black*, hath very large bunches, the berries are large and inclining to an oval form; this grape will ripen tolerably out of the ſtove, if the autumn proves kind, but not before the end of October.—(11.) *Raiſin Grape*, hath very large bunches; the berries hang very looſely; they are of an oval form, but will not ripen here without being forced by artificial heat. (12) *Aleppo, or Syrian Grape.* The bunches of this grape are the largeſt yet known, ſome weighing at leaſt a dozen pounds, the berries are large and white, growing looſely; they are of a good flavour, and their ſkins being tough can be kept a conſiderable time after they are ripe; this kind ſhould be conſtantly kept in the ſtove.

The above enumerated varieties, which are of the moſt approved and eſteemed ſorts, are ſufficient to continue by forcing, and againſt the common walls, a ſucceſſion of fruit from May to November, the major part of them being the higheſt flavoured grapes hitherto known.

To theſe may be added ſeveral other varieties of this ſpecies; but as they are little eſteemed among the curious in fruits, the mentioning them may paſs unnoticed.

*Of their Propagation.*

The general propagation of grape Vines is either by layers or cuttings; the method of encreaſe by layers is practiſed as follows: in autumn or winter make choice of a ſtrong prolific ſhoot, of two years growth, ariſing from near the ground, and of the kind you would wiſh to propagate; let this ſhoot be bent down in the earth ſix or eight inches deep at the part where the laſt ſummer's ſhoot iſſued from; this ſhould be pegged down to prevent its being diſturbed and ſhortened at the top to two or three eyes; the next autumn following the layer will be ſufficiently furniſhed with roots for tranſplantation, when it may be cut from the parent plant, and placed where it is intended to remain: but to inſure the layer's ſucceſs by ſuch removal ſeveral perſons have trained them through the holes of flower-pots, in theſe they have taken root, and in the winter, if they are ſeparated from the mother plant, they may be turned out of the pot undiſturbed, and planted with the roots entire, where it may be thought proper. But the moſt preferable way to encreaſe this plant is by cuttings in the choice of which thoſe of a ſtrong vigorous growth, with the buds not far diſtant from each other, ſhould be preferred, obſerving, that ſuch cuttings have very thick turged, blunt buds, as theſe are moſt prolific, avoiding thoſe which are not well ripened, or have their buds pointed. In taking off ſuch cuttings, it is proper to cut them an inch or two in the former year's wood, below the place where the laſt year's ſhoot is produced from; for at this joint the roots will ſpring out and form the plant. In ſhortening theſe cuttings, obſerve to cut them in lengths of three, four, or five eyes, according to their diſtance from each other: the cuttings thus ready (which may be taken from the parent plant any time between November and February) ſhould be laid with their lower part in the ground, and covered in hard weather with litter, where they may remain till the ſeaſon of planting arrives, which is the beginning of April; they ſhould then be taken up cleanſed and planted, where they are intended to remain, and perfect themſelves, as they are not to be removed again, whether for walls or vineyard. The ſoil for grape Vines requires ſome conſideration; if the ground is of a wet nature or a ſtrong ſtiff clay, it is the moſt improper for theſe plants, as the cuttings or layers will grow very luxuriant, but will produce very ill flavoured grapes, owing to the redundancy of moiſture

moiſture with which the plants are ſaturated; a rich light ſoil is therefore to be preferred; for notwithſtanding the notion of many gardeners, in putting a ſtratum of ſtones, brick, rubbiſh, &c. to impoveriſh the ſoil with a view to render the Vines more prolific, it only ſtunts the growth of the plants, and cauſes the fruit to be ſmall and trifling, whereas, if they have a rich ſoil the ſhoots will grow ſtrong, eſpecially where they can have extent to run, and the bunches will be proportionally large and handſome. The ſoil being ready for the reception of the cuttings, let them be planted againſt the wall, at about ſix inches aſunder, and at ſuch a depth as but one eye of the cutting may appear above ground, obſerving to preſs the ground tight about them, and if the ſeaſon proves dry let them occaſionally have a little water; but where there is the conveniency of a ſtove in February the cuttings may be planted each in a ſmall pot, and plunged in the bark-bed; here they will quickly take root, and in the courſe of the ſummer make a very great progreſs, ſo much as to gain a year of thoſe planted in the common ground, obſerving, as the pots are filled with roots, to ſhift the plants into others of a ſize larger, and thus ſhould be occaſionally repeated when neceſſary; the plants thus forwarded ſhould in autumn be inured to the open air, and turned out of the pots with their balls into the places where they are intended to remain. With reſpect to the aſpect theſe plants require, let it be remembered, that all aſpects are improper for grape Vines, excepting the ſouth and ſouth-weſt, as in other ſituations ſcarcely any bunches will ripen in this cloudy changeable climate.

*Firſt Year's Management of Cuttings.*

When the cuttings begin to ſhoot let them be examined, and leave only two, if ſo many ariſe, thoſe which appear the ſtrongeſt ſhould be choſen; about a month after, the ſhoots will have made ſome progreſs ſo as to ſhew which is likely to be the ſtrongeſt; this ſhoot ſhould be preſerved, carefully nailing it againſt the wall, to prevent its being broke by the wind, obſerving to rub off the other; in the courſe of the ſummer, as the ſhoot advances, continue to keep it nailed up, and let all lateral ſhoots be ſtripped off as they are produced; this, with keeping the ground clear from weeds, and occaſionally watering in dry weather, is all that the plants require in their ſummer's management: when the leaves turn yellow and begin to drop, the ſhoot which has been reſerved ſhould be topped down to two eyes; theſe will produce ſhoots the ſucceeding ſummer.

*Second Year's Management.*

The ſpring following the borders may be enriched and dug up ſo as not to diſturb the roots of the Vines: in April and May the ſhoots from the eyes which were left will be of a conſiderable length, each ſhould be tacked to the wall to prevent their being broke by the winds, rubbing off all lateral ſhoots as they are produced, and this work ſhould be repeated occaſionally, till the ſhoots have done growing, obſerving to keep the ground entirely free from weeds during the ſummer. The November following, the operation of pruning ſhould be performed by ſhortening the weakeſt of the ſhoots to two eyes, and letting the ſtrongeſt be left to four, ſix or eight eyes according to its ſtrength; for if the principal ſhoot is very ſtrong, the greater length ſhould it be cut to, and the more probability there is of its producing fruit the ſucceeding ſummer.

*General future Management.*

The ſame care will be required the third year, &c. for in April or May, according to the forwardneſs of the ſeaſon, the ſhoots of the Vines will have made ſome progreſs, which ſhould be properly attended to, this is by diſplacing all unneceſſary ſhoots, leaving none but thoſe which have the appearance of producing bunches, or furniſhing ſhoots for the ſucceeding year; theſe ſhould be laid cloſe to the wall in a regular manner; for, if neglected, the firſt violent wind may break them off, and if not, the ſhoots will ſoon run into confuſion; the omiſſion of this neceſſary work will alſo be attended with other bad conſequences, for the growth of the bunches will be retarded, and the ſhoots, intended for the ſupply of the next year, will be ſo much ſhadowed and ſtopped in their growth as to prevent the wood from obtaining its proper ripeneſs, ſo as to be able to furniſh good bunches in future. The ſame attention ſhould be paid the Vines in the following months, obſerving to keep them nailed up as they advance, diſplacing all uſeleſs, ſtraggling,

ſtraggling, and lateral ſhoots. As they are produced in Auguſt, the extremities of the fruit-bearing branches may be ſhortened, as alſo thoſe which have run out of bounds to a very great length; this ſtopping the ſhoots will aſſiſt the bunches to ſwell their berries out, and forward their ripening; and if that or the former month proves very dry and hot, let them be moderately watered: this will keep the Vine in a ductile ſtate, and be a great addition towards increaſing the ſize of the bunches; but when the fruit is full grown, watering ſhould be diſuſed as it would debaſe the flavour of the berries. When the grapes are approaching to ripeneſs they ſhould be guarded from the ravages of birds, waſps, and other inſects: they may be protected from birds, by placing a net over the Vine; but this prevents not the waſps, &c. from preying on the fruit, therefore, to hinder theſe inſects from making their depredations, provide ſome fine crape, which being cut to a proper ſize, bags may be made ſo as to fit the principal hunches: black crape is beſt, as it is of a colour which abſorbs the rays of light, and aſſiſts by its warmth the ripening of the bunches. But as our climate will not ſufficiently ripen the finer ſorts of grapes, I ſhall conciſely mention the method of obtaining them in perfection.

*Forcing Grape Vines.*

Various buildings have been contrived to effect the ripening of thoſe kinds of grapes, which cannot be effected in the open ground, as likewiſe for the earlier ſorts to be fit for the table in May, June, or July. The conſtruction of theſe kinds of buildings are different, though all anſwering the ſame purpoſe: ſome are conſtructed with flues ranging within the wall where the Vines are trained up; but as the Vines would receive more heat at times by being cloſe to the wall than is proper, a lattice work is generally detached therefrom, to which the branches are trained, and the whole is covered with a range of ſloping glaſs; but the more common method is to train them under the ſloping glaſſes of the pine-apple ſtove, the Vines are generally planted cloſe on the outſide, and trained in through holes contrived for the purpoſe; in ſuch places there is a certainty of the grapes ripening in perfection, obſerving always to train freſh ſhoots from without every year that there may be no want in the choice of wood; their management differs but little from thoſe of the common walls, therefore needs no repetition.

The other ſpecies of Vines are thoſe which more excite curioſity than are of real uſe.

[2] VITIS *Labruſca.*

*Virginian Grape.*] Hath a climbing ſtalk furniſhed with large, trilobate, heart-ſhaped leaves, downy on their underſide and indented on their edges; the flowers are produced in bunches, and are ſucceeded by round rough-flavoured black fruit.

[3] VITIS *Vulpina.*

*Fox Grape.*] The leaves are large and ſmooth on both ſides, of a heart-ſhaped figure with idented edges; the flowers grow in bunches, and are ſucceeded by black berries of a very diſagreeable ſtinking flavour.

[4] VITIS *Caciniatis.*

*Parſley-leaved Grape.*] The leaves of this ſort are finely divided, the ſtem is thick, bearing ſtrong ſhoots, but the fruit is of no account.

[5] VITIS *Arborea.*

*Pepper-tree Grape.*] The ſhoots of this ſort are rather weak, but admired for the beauty of its leaves, which are ſupradecompound, of a fine green colour, are compoſed of a multitude of delicate folioles; the flowers come out in bunches from the wings of the ſtalks, and are ſucceeded by berries of the ſize and form of pepper.

All theſe ſpecies are propagated by cuttings, layers, or ſuckers.

# W.

WALTHERIA. *Waltheria.*

The plants are woody exotics, from the warm parts of America and India, and retained here in ſtoves for variety; riſing with woody ſtems, from two or three to four or five feet high, adorned with oval and ſpear-ſhaped leaves, and bunches of pentapetalous flowers.

Claſs and order, *Monadelphia Pentandria.*

*Characters.*] CALIX, is monophyllous, cyathiform or cup-ſhaped, five-parted, and permanent.——COROLLA, five heart-ſhaped, ſpreading petals.——STAMINA, five ſhort, monadelphous filaments, having diſtinct antheræ.—PISTILLUM, an oval germen, ſlender ſtyle, and pencilled ſtigma.—PERICARPIUM, an oboval, bivalved, unilocular capſule, and one obtuſe ſeed.

The ſpecies are,

[1] WALTHERIA *Americana.*

*American Waltheria.*] Riſes with a ligneous ſoft ſtalk, branching ſparingly two or three feet high; large, oval, plicated, ſawed, indented leaves; and from the upper parts of the branches round heads, or bunches of yellow flowers, on proper peduncles.

[2] WALTHERIA *Indica.*

*Indian Waltheria.*] Riſes with a woody ſtem, dividing and branching eight or ten feet high; having ſoft, woolly branches; large, oval, ſerrated, plaited leaves; and ſmalliſh yellow flowers, in round bunches, ſitting cloſe, without peduncles or foot-ſtalks.

[3] WALTHERIA *Anguſtifolia.*

*Narrow-leaved American Waltheria.*] Riſes with ligneous ſtalks, dividing and branching ſix or ſeven feet high; ſpear-ſhaped ſawed leaves; and round bunches of yellow flowers, on proper peduncles.

They all flower in ſummer, continuing in ſucceſſion ſeveral months; ſucceeded by ripe ſeeds in autumn.

All the three ſorts are ſomewhat ſhrubby; durable in ſtem and branches, at leaſt for ſeveral years; though, as they are generally raiſed from ſeed, they arrive to perfection in two years, ſo as to flower and produce ſeeds; and ſometimes continue ſeveral years, and flower annually in ſummer.

As they are tender exotics from hot countries, they muſt always be kept in a ſtove here.

They are propagated by ſeed, ſowed in a hot-bed; and when the plants are fit to remove, plant them ſeparately in pots, and plunge them in the bark-bed; and managed as other woody plants of the ſtove collection.

WINTERANIA. *Winterania.*

It is of the tree kind; a native of South America; requiring the indulgence of a ſtove in this country, where it is cultivated for variety; having oblong leaves and pentapetalous flowers.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX is bell-ſhaped, trilobed, with the lobes roundiſh and concave.—COROLLA, five oblong, ſeſſile petals, longer than the calix; and a conical, pitcher-ſhaped NECTARIUM.——STAMINA, no filaments; but twelve or ſixteen linear diſtant antheræ, affixed to the outſide of the nectarium.—PISTILLUM, an oval germen; cylindric ſtyle, with three obtuſe ſtigmas.——PERICARPIUM, a roundiſh, trilocular berry, with two heart-ſhaped ſeeds.

There is but one ſpecies, which is wholly a fine aromatic.

WINTERANIA. *Canella.*] Riſes with a thick, woody ſtem, branching on every ſide, almoſt the whole length, growing near twenty feet high; having a lightiſh-coloured aromatic bark; oblong, obtuſe, light-green leaves; and red flowers, in umbellate cluſters, at the ends of the branches, ſucceeded by roundiſh berries.

This

This tree, being a native of the hot parts of America, muſt always be kept in a ſtove in this country, and plunged moſtly in the bark-bed.

It is propagated by ſeeds, and cuttings in pots, and plunged in the bark-bed; alſo by layers; though the ſeeds are generally the moſt certain method of raiſing them; which are procured from America by the ſeedſmen, for the cuttings and layers root but reluctantly.

# X.

XERANTHEMUM. Eternal flower.

This genus furniſhes herbaceous annuals, and ſhrubby perennials for the pleaſure-ground and green-houſe collection; riſing with upright, branchy ſtems, from two or three, or four feet high; and ſome of procumbent growth, garniſhed with ſpear-ſhaped, and oblong, roundiſh, and oval leaves in the different plants; and compound flowers.

Claſs and order, *Syngeneſia Polygamia, Superflua.*

*Characters.*] CALIX, a compound flower, having the general calix compoſed of many long ſpear-ſhaped ſcales.—COROLLA, compoſed of many hermaphrodite florets in the diſc, each conſiſting of one funnel-ſhaped petal, five parted at top; and tubular female florets in the radius, more ſlightly cut at the brim.—STAMINA, five very ſhort filaments, and long cylindric antheræ.—PISTILLUM, a ſhort germen; filiform ſtyle, having a bifid ſtigma in the hermaphrodites; and in the females two reflexed ſtigmas.—PERICARPIUM, none; each floret ſucceeded by an oblong, coronated ſeed, placed on the receptacle.

The plants of this genus derive the name Eternal Flower, from the great durability of the flowers, which being gathered when fully blown, will retain their beauty many months. There are many ſpecies, but the moſt remarkable of which are the following, conſiſting of a hardy herbaceous annual, and ſome tender ſhrubby plants.

*Hardy Annual Kind.*

Compriſes the common Eternal Flower, furniſhed with ſeveral varieties, all hardy annuals.

XERANTHEMUM *Annuum.*

*Annual Xeranthemum, or Common Eternal Flower.*] Riſes with an herbaceous, angular, downy, branching ſtalk, two or three feet high; ſpear-ſhaped, ſpreading, hoary, cloſe-ſitting leaves; and all the ſtalks and branches, terminated by large flowers ſingly, of different colours in the varieties, appearing in July, Auguſt, and September, and are very ornamental, ſucceeded by ripe ſeeds in autumn.

*Varieties are.*] Large white-flowered.—Purple-flowered.—Double white-flowered.—Double purple flowered.—Double violet coloured.

The flowers of all theſe varieties are of the compound kind; conſiſting of many ſmall florets in one common calix, together forming one large flower, which in all the ſorts is very ornamental, and in high eſtimation for the ſingularity of their durable beauty, even after being gathered; for if gathered when fully blown in dry weather, with part of the ſtalk to each, and hung up to dry in a ſhady place, they will retain their reſpective colours in full beauty all winter, and by placing the ſtalks in glaſſes or pots, not with water, but ſand to make them ſtick faſt, and placed in any apartment of a houſe, they will appear very ornamental.

They are all eaſily propagated by ſeeds ſowed in the full ground, in autumn or ſpring, or in both ſeaſons; as the autumn raiſed plants will flower earlier and ſtrongeſt, and the ſpring plants will ſucceed them, and thereby continue the ſucceſſion of flowers proportionably longer.

Sow them for tranſplantation in any bed or border of good light earth, either on the ſurface and raked in, or in drills half an inch

inch deep, and five or ſix inches aſunder; and when the plants are come up two or three inches high, thin out a quantity of the ſtrongeſt, and prick them either in beds in rows a foot aſunder finally to remain; or in patches about the different borders to flower in aſſemblage with other hardy annuals; giving water as ſoon as planted, and repeated occaſionally in dry weather till they have taken good root, and they will require no farther care except keeping them clean from weeds.

Or the ſeeds may be ſowed in patches in the different borders, in the places where you intend the plants ſhall flower.

# Y.

## YUCCA.

Adam's Needle.

This genus conſiſts of ſhrubby ſucculent evergreens of America, both hardy and tender kinds, to diverſify the pleaſure-ground and green-houſe collections, riſing with upright, thick, woody ſtems ſeveral feet high, adorned at top with cluſters of very long, aloe-like, ſtiff leaves, ending in long ſharp ſpines; and at top, from among the leaves, long ſpikes of bell-ſhaped, ſix-parted, liliaceous flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none.—COROLLA, is monopetalous, bell-ſhaped, and divided into ſix large oval ſegments.—STAMINA, ſix very ſhort reflexed filaments, having ſmall antheræ.—PISTILLUM, an oval three-cornered germen longer than the ſtamina, no ſtyle, but an obtuſe three-furrowed ſtigma.—PERICARPIUM, an oblong, triangular, trifid, trivalved capſule of three cells, containing many ſeeds lying over one another in a double ſeries.

There are four ſpecies of Yucca, all of which are of ſingular growth; they riſing with erect ſtems from two or three to ſix or eight feet high, terminated by a large tuft of very long leaves, reſembling thoſe of the aloe, but much narrower; have all durable ſtems and evergreen leaves; are natives of different parts of America, and two of them are moderately hardy to grow here in the full ground; and the other two being more tender, require ſhelter of a green-houſe in winter.

*Hardier Kinds.*

[1] YUCCA *Glorioſa.*

*Glorioſus Yucca, or Common Adam's Needle.*] Riſes with an erect, ligneous, thick ſtem, two or three feet high, having very long, narrow, ſtiff, entire leaves, ending in a long ſharp, black-ſpine, garniſhing the ſtem almoſt to the bottom and in a large tuft at top; and from the center of the top leaves riſes a long branching peduncle, ſuſtaining a panicle of bell-ſhaped white and purple flowers.

[2] YUCCA *Filamentoſa.*

*Filamentoſe or Thready Virginia Yucca.*] Riſes with an upright, thick, ligneous ſtem two or three feet high, adorned at top with a tuft of very long, ſpear-ſhaped, ſtiff, blunt-pointed, ſawed filamentoſe leaves, emitting long threads from the ſides, hanging downward; and from the top of the ſtem amidſt the leaves an erect peduncle or flower-ſtalk, ſeveral feet high, garniſhed with many large, white, and purple-ſtriped leaves.

Both theſe ſpecies flower in Auguſt and September, and make an ornamental appearance, but are not ſucceded by ſeeds in England.

They are natives of North America, the former that of Canada, and the latter of Virginia, and are both tolerably hardy; ſo as after having little occaſional ſhelter whilſt young, for two or three winters, they may be turned out into the open ground in a ſheltered ſituation in the ſhrubbery; though it is alſo proper to keep ſome always in pots, and treated as green-houſe plants, as a reſerve in caſe thoſe in the open ground ſhould be cut off in very ſevere winters.

*Tender Kinds for the Green-houſe.*

[3] YUCCA *Aloifolia.*

*Aloe-leaved Yucca.*] Riſes with an erect, thick, fleſhy ſtem, eight or ten feet high,

crowned with a large tuft of long narrow, ſtiff, crenated, aloe-like leaves ending in ſharp ſpines; and from the center of the crown of leaves come out the flower-ſtalk, branching pyramidally two or three feet high, having all the branches terminating in a ſpike of flowers, purple without and white within, appearing in Auguſt and September.

4 YUCCA *Draconis.*

*Dragon Tree-leaved Yucca.*] Riſes with an upright, thick, brown ſtem, three feet high, crowned with long, narrow, ſerrated leaves ending in ſpines and nod downward; and in the center of the leaves ariſe, the flower-ſtalk very branchy, with all the branches terminating in ſpikes of fleſh-coloured flowers in Auguſt and September.

All theſe four ſpecies of *Yucca*, being of ſingularly curious growth; they are worthy of culture in every good collection, keeping ſome of all the ſorts in pots, to move to ſhelter of a green-houſe in winter; as they will afford a conſpicuous and entertaining variety in this collection; and ſome plants of the two firſt ſorts may alſo, after attaining a little ſtrength and gradually hardened, be planted out in the full ground in ſome dry warm ſituation, ſheltered by adjacent ſhrubs and trees.

As all the ſorts are of a ſucculent nature, they ſhould always be planted in a light dry ſoil; if ſomewhat ſandy the better.

The propagation of all the ſorts is by off-ſets and ſuckers, from the root and head of the plants; alſo by ſeed.

By off-ſets, &c.—Theſe may be detached almoſt any time, in ſpring and ſummer, and lay them in ſome dry place for a few days, till the wounded part made by ſeparation from the plant is dried and healed over, then plant them in pots of light ſandy compoſt, and place them in a ſhady place till they have taken root.

By Seed.—This is obtained from abroad, and ſhould be ſowed in the ſpring in pots of light earth, and plunged in a hot-bed; in which the plants will ſoon come up, and when they are two or three inches high, prick them ſeparately in ſmall pots of light ſandy mould, plunging them alſo in a hot-bed to forward their growth, aſſiſting them with moderate waterings and freſh air daily; and harden them by degrees to the full air in June and July, to remain till October, then removed into the green-houſe.

# Z.

ZANTHOXYLUM. The Tooth-ach Tree.

This plant is a woody hardy exotic, growing naturally in North America, riſing to the height of twelve or fourteen feet, furniſhed with large pinnate leaves and dioecious flowers, growing in ſpikes.

Claſs and order, *Dioecia Pentandria.*

*Characters.*] *Male flower.*—CALIX, a perianthium deeply cut into five oval coloured parts.—COROLLA, none.—STAMINA, five awl-ſhaped erect filaments, with didymous, ſulcated, roundiſh antheræ.—*Female flower*, CALIX, as the male, COROLLA, none.—PISTILLUM, a roundiſh germen, an awl-ſhaped ſtyle, with an obtuſe ſtigma.—PERICARPIUM, an oblong capſule, formed of two valves and one cell, containing a ſingle ſmooth roundiſh ſeed.

The name of Tooth-ach Tree being applied to this plant, ariſes from the uſe made of the bark in cleanſing the teeth, and preventing that troubleſome diſorder among the inhabitants of Canada.

This ſpecies is called

ZANTOXYLUM *Clava Herculis.*

*Canada Tooth-ach Tree, or Hercules's Club.*] It grows to the height of twelve feet, with a rough bark armed with ſhort ſpines; the leaves are winged, of a dark green colour, growing irregularly on the branches, each conſiſt of four or five pair of ſpear-ſhaped folioles, which are terminated by an odd one; the flowers come out from the ends of the branches

branches in looſe panicles; they being apetalous have no great appearance, and are ſucceeded by unilocular capſules, containing the ſeeds.

*Variety.*] The aſh-leaved Tooth-ach Tree, with oval, oblong, folioles, and prickly midribs.

This tree is propagated by ſeeds and layers, or cuttings ſtruck in a moderate hot-bed, and afterwards inured to the open air.

ZINNIA.

A genus of annual plants, cultivated for ornamenting the pleaſure and flower-gardens, growing with erect ſtalks, garniſhed with oblong leaves, and producing radiated flowers.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, the general cup is oval, cylindric, and imbricated, with many blunt, upright, perſiſtent ſcales.—COROLLA, compound and radiated, conſiſting of hermaphrodite florets, placed in the diſc, and female ones, which are ligulated, and form the rays.—STAMINA, of the hermaphrodites are five ſhort filaments, with cylindric tubuloſe antheræ.—PISTILLUM, an oblong ariſtated germen, with a ſlender ſemibifid ſtyle, and two erect obtuſe ſtigmas; in the female flowers the germen is oblong and triquetrous, with a capillary ſtyle, and two recurved ſtigmas.—PERICARPIUM, the calix containing oblong ſolitary ſeeds crowned with down, and placed on a paleaceous receptacle.

Of this genus there are two ſpecies.

[1]ZINNIA *Pauciflora.*

*Yellow Zinnia.*] The root of this plant is fibrous, from which ariſes the ſtalk to about three feet high; it is woody below, and branches upwards, which are placed oppoſite; theſe are furniſhed with oblong leaves of a pleaſing green colour, the flowers terminate the ends of the branches on long foot ſtalks; they are of a yellow colour, which decays till the ſeeds are ripe.

[2]ZINNIA *Multiflora.*

*Red Zinnia.*] This plant is alſo annual; the ſtalk riſes erect with upright branches, theſe are channelled and hairy; the leaves are oval, lanceolate, and placed oppoſite; the flowers come out at the extreme part of the branches, the florets of the diſc are yellow, and thoſe which form the rays are of a duſky red; theſe continue till the ſeed is ripe, which is in autumn.

Theſe plants being annual are propagated from the ſeeds which ſhould be ſown on a ſlight hot-bed; in March, and afterwards, when the plants ariſing are a few inches high, they ſhould be pricked out on another bed previouſly prepared to receive them; here they may remain till the advance of ſummer, when they may be taken up and tranſplanted in the borders of the pleaſure or flower garden, where they will blow and complete their ſeeds for the next year.

ZYGOPHYLLUM.

Bean Caper.

It furniſhes herbaceous and woody ſucculent exotics of Aſia and Africa, cultivated here for variety in the pleaſure ground and green-houſe collections: riſing with erect ſtalks three or four feet high, adorned with oval, oblong, and ſpear-ſhaped, fleſhy, ſucculent leaves, and pentapetalous flowers along the ſides of the branches.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, five oval, obtuſe, concave, erect leaves.—COROLLA, five obtuſe petals emarginated at top, and a ten-leaved cloſed nectarium, which includes the germen.—STAMINA, ten awl-ſhaped filaments and oblong incumbent antheræ.—PISTILLUM, an oblong, germen, awl-ſhaped ſtyle, crowned by a ſimple ſtigma.—PERICARPIUM, an oval, pentagonous, quinquevalvulous capſule of five cells, having many roundiſh ſeeds.

There are ſeveral ſpecies, one is herbaceous and moderately hardy, with perennial roots and herbaceous annual ſtalks; the others are of a woody durable growth, and tender, requiring ſhelter of the green houſe in the winter. The principal ſorts in the Engliſh gardens, are the following.

[1]ZYGOPHYLLUM *Fabago.*

*Fabago or Common Bean Caper.*] Hath a thick, fleſhy, deeply ſtriking, perennial root; upright, round, ſmooth, jointed, herbaceous, green ſtalks, three or four feet high; garniſhed with oval, ſmooth, fleſhy, blueiſh-green leaves two or three together on each petiole; and reddiſh flowers, by two or three together at the axillas of the ſtalks, appearing in July, ſucceeded by long capſules, containing the ſeed, ripening in autumn.

It is durable in root, but the ſtalks, being herbaceous, periſh every autumn; is tolerably hardy, only requiring a little ſhelter in winter when young, afterwards may be planted in the full ground in the borders in any dry light ſoil, there finally to remain; where they will abide many years by the root, and ſend up ſtalks and flower abundantly, and ripen ſeeds.

As it is of a ſucculent nature, it ſhould have a dry rubbiſhy ſoil.

It is propagated by ſeeds ſowed in the ſpring; ſome in a hot-bed to bring them forward, and ſome on a warm border; and when the plants are come up about two inches high, plant ſome out in ſmall pots ſeparately, and plunged into a hot-bed to facilitate their rooting, and forward their growth; but harden them by degrees to the full air; others may be planted in a warm border to take their chance, allowing thoſe in the pots ſhelter of a garden-frame in froſty weather, and in ſpring ſome of them may be turned out into the full ground where they are to remain.

*Tender Green-houſe Kinds.*

Theſe are moſtly of a ſhrubby nature, durable in root, ſtem, and branches, garniſhed with ſucculent leaves.

[2]ZYGOPHYLLUM *Seſſilifolium.*

*Seſſile-leaved African Bean Caper.*] Riſes with an upright woody ſtem, branching numerous and irregularly, three or four feet high; oval, ſpear-ſhaped, thick, ſmooth, ſucculent ſeſſile leaves, ſurrounding the branches by fours; and yellow flowers on long, ſlender footſtalks at the ſides of the branches, in ſucceſſion great part of ſummer.

*Varieties.*] Yellow flowered—Sulphur-coloured flowers—White-flowered—Copper-coloured, having moſtly a reddiſh or brown ſpot near the baſe of each petal.

[3]ZYGOPHILLUM *Morgſana.*

*Morgſana, or Purſlane-leaved Æthiopian Bean Caper.*] Riſes with a ſhrubby ſtem, dividing and branching irregularly, three or four feet high; oval, thick, obtuſe ſucculent leaves, ſurrounding the branches by fours; and ſulphur-coloured flowers on long foot-ſtalks from the ſides of the branches, appearing moſt part of ſummer.

Both theſe tender ſpecies being natives of the warm parts of Africa; they require ſhelter of a green-houſe in this country in winter, planting them in pots of light ſandy earth, as being ſucculent, and manage them as other plants of ſimilar quality. See GREEN HOUSE PLANTS.

They are propagated eaſily by cuttings and by ſeed.

By Cuttings.—Theſe may be planted any time in the ſpring or ſummer; if in ſpring about March or April, plant them in pots, and if plunged in a hot-bed, and frequently watered, they will quickly emit roots, and ſhoot at top; and if in the ſummer months, plant them in a ſhady place, or in pots placed in the ſhade, giving frequent waterings, they will alſo take good root; and in either method pot them off ſeparately towards autumn in order to be moved into the green-houſe or glaſs-caſe, in October.

By Seed.—The plants ſometimes produce ſeeds in this country, or are procured from abroad by the ſeedſmen; ſow them in ſpring in pots of light earth, and plunge them in a hot-bed, where they will ſoon come up, and when a little advanced in growth, prick them in ſeparate ſmall pots, watered and plunged again in the hot-bed till well rooted, then hardened gradually to the full air in June and July, to remain till October, then placed in the green-houſe, &c.

ADDENDA.

# ADDENDA.

A.

AGARIC. Muſhroom. See the article SPAWN.

ALSTROEMERIA.

Conſiſts of ſtove plants, which are perennial and herbaceous, bearing very ornamental hexandrious flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none.—COROLLA, hexapetalous and ſublabiated, the three outward petals are wedge-ſhaped and retuſe, the interior petals are ſpear-ſhaped, the two lower ones of which are tubuloſe at the baſe. STAMINA, ſix ſubulate, declining, unequal filaments, with oblong antheræ.—PISTILLUM, a top-ſhaped, ſix-angled germen, which is placed below the flower; the ſtyle is declining and ſlender, topped with three oblong bifid ſtigmas.—PERICARPIUM, a roundiſh ſixangular mucronated capſule, opening with three valves, containing three cells, filled with many globoſe ſeeds: there are three ſpecies of this genus.

[1]ALSTROEMERIA *Pelagias.*

*Peruvian ſpotted purpliſh Alſtroemeria.*] Hath a fibrous root, from which ariſe many herbaceous ſtalks, about three feet high; on theſe the leaves are pretty thick ſet, and continue all the winter, each of which are oval, ſpear-ſhaped, reflexed, and of a dark-green colour, from the extremities of the branches, the flowers come out, two or three together, on long foot-ſtalks, they are compoſed of ſix petals; the outer ones are white, with a large, reddiſh purple ſpot in the middle of each; the interior petals are ſpotted with purple; they are ſucceeded by a hexangular capſule, containing many ſeeds.

[2]ALSTROEMERIA *Ligta.*

*Striped Alſtroemeria.*] Hath a riſing ſtalk, with ſpear-ſhaped leaves, and ſtriped purple flowers

[3]ALSTROEMERIA *Salſilla.*

*Climbing Alſtroemeria.*] Hath a twining ſtalk, with ſpear-ſhaped leaves placed alternately; the flowers come out from the ſides of the ſtalks, and are of a purple colour.

Theſe plants are retained in the ſtove, though they will thrive in the green-houſe; their beautiful flowers come out in May, and frequently blow all the ſummer months; they are propagated by cuttings ſeeds or parting their roots, which may be done any time in the ſpring, giving them the aſſiſtance of a hot-bed.

AMETHYSTEA.

We know but of one ſpecies of this genus; it is a native of Siberia, and an hardy annual.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, is monophyllous, tubulately companulated, and five-parted at the margin.—COROLLA, monopetalous and ringent.—STAMINA, two ſlender filaments, and ſimple antheræ.—PISTILLUM, quadrifid germen, with a ſingle ſtyle topped with two acute ſtigmas.—PERICARPIUM, none; the cup containing four obtuſe ſeeds.

This plant riſes with an upright ſtalk to the height of about a foot, with a few lateral branches towards the top, on the extremities of which the flowers are produced in ſmall umbels of a rich blue colour, which make an elegant appearance; the leaves are trifid, ſerrated, and of a dark green; the flowers come out in June or July, and when the ſeeds are ripe, may be immediately ſown, where the plants are to remain, as they will not thrive well by tranſplanting.

AMYGDALUS PERSICA.—Add after *Early Newington Peach,*

*Galland Peach.*] A middle-ſized round fruit, of a very deep red all over, eſteemed the fineſt flavoured Peach of any yet known; ripe the beginning of Auguſt.

ANNUAL PLANTS. Such as are only of one year's duration, riſing from ſeed in the ſpring, &c. arrive to full growth the enſuing ſummer, and produce flowers and ſeed; then totally periſh, root and top, in autumn or winter following.

Plants of the Annual Tribe are very numerous, principally all of the herbaceous kind; conſiſting both of eſculents, and of the flowry race, as ornamental plants, which latter are commonly called ſimply *Annuals*, and of which there are both hardy and tender kinds; the hardy Annuals being ſuch as will grow from ſeed in the open ground; and the tender Annuals are ſuch as require to be raiſed and forwarded in a hot-bed, as is explained in the culture of the reſpective ſorts in their reſpective genera.

C.

CALICARPA,—*add,*

*Characters* ] CALIX, monophyllous and bell-ſhaped.—COROLLA, monopetalous and tubuloſe, with the brim cut into four obtuſe ſpreading parts.—STAMINA, four ſlender filaments double the length of the corolla, with oval antheræ.—PISTILLUM, a roundiſh germen, the ſtyle ſlender, with a blunt ſtigma. PERICARPIUM, a ſmooth round berry, containing four oblong ſeeds.

*After* cuttings, *ibid. add,*

but ſhould be ſheltered from the ſeverity of hard weather, particularly when young.

CHIRONIA, ſhrubby African Centaury.

This genus conſiſts of two ſpecies of ſhrubs, which are natives of Africa, and require ſome ſhelter in winter.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, monophyllous, divided into five parts.—COROLLA, monopetalous, tubular, with the border cut into five ſpreading parts.—STAMINA, five broad filaments, growing to the top of the tube, and topped with oblong antheræ.—PISTILLUM. an oval germen, ſlender ſtyle, and a capitated ſtigma.——PERICARPIUM, oval and biocular; the ſeeds are numerous and ſmall.

The ſpecies are,

1 CHIRONIA *baccifera.*

*Shrubby berry-bearing African Centaury.*] Chironia with round-jointed ſtalks, divided into various branches upward, and furniſhed with ſhort, narrow, fleſhy leaves; the flowers are of a fine red colour, and produced at the extremities of the branches; they continue in ſucceſſion all the ſummer and autumn months, and ſometimes in favourable ſeaſons produce ſeeds.

2 CHIRONIA *fruteſcens.*

*Shrubby African Centaury with capſules.*] Chironia with a round ſtalk, producing ſeveral erect branches, and growing to the height of between two and three feet; at the ends of each ſhoot, the flowers which are tubulous and ſpreading are produced; they are of a bright ſcarlet colour, and make a gay appearance; they are in bloom all the ſummer, and the ſeeds ripen in autumn.

*Propagation.*

Both ſorts are raiſed from ſeeds on a hot-bed in the ſpring, and, when arrived at ſome tolerable ſize, may be inured to the open air in ſummer, but require ſhelter in an airy glaſs-caſe in winter, and muſt have but little water; the ſoil they beſt thrive in is a light ſandy earth: they may alſo be propagated by cuttings.

CHRYSOBALANUS, Cocoa Plum-tree.

A genus of trees growing in ſeveral parts of the Weſt Indies.

Claſs and order, *Icoſandria Monogynia.*

*Characters.*] CALIX, monophyllous and bell-ſhaped.—COROLLA, conſiſts of five oblong, ſpreading petals, inſerted in the calix. —STAMINA, many filaments inſerted in the calix, and ſmall twin antheræ.—PISTILLUM, an oval germen, with a ſtyle of the ſhape and length of the ſtamina, with a blunt ſtigma. —PERICARPIUM, a large oval berry of one cell, containing a rough oval nut.

The ſpecies are,

1 CHRYSOBALANUS, *Icaco.*

*Cocoa Plum-tree.*] Chryſobalanus with a ſhrubby ſtalk riſing about eight or ten feet high, from which iſſues ſeveral branches, which are furniſhed with ſtiff, oval, indented leaves from the wings of theſe, and at the ſeparation of the branches, the flowers come out in looſe bunches; they are ſmall and of a white colour; theſe are ſucceeded by berries which are of different colours, and of the ſize of a middling plum.

2 CHRYSOBALANUS *Purpurea.*

*Chryſobalanus with decompounded leaves.*] This ſpecies hath a ſhrubby ſtalk like the former, but differs in the foliage, being winged and branched, each branch conſiſting of ſix or ſeven pair of oval entire folioles.

*Propagation.*

Theſe trees are propagated by the nuts, which muſt be procured from the Weſt Indies; they muſt be ſown in the ſpring on a hot-bed, and when the plants have riſen high enough; they may be tranſplanted ſingly into pots, and plunged into the bark-bed in the ſtove, obſerving to ſhade them from the ſun till they have taken freſh root, in which place they muſt always be continued.

CHRYSOPHILLUM, Star-apple-tree.

It grows naturally in the Weſt Indies, where it is cultivated for its fruit, which is aſtringent and rough to the palate, unleſs mellowed by keeping, when it becomes very agreeable to the palate.

Claſs

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a ſmall cup divided into five parts.——COROLLA, monopetalous and bell-ſhaped, with the border cut into five parts.—STAMINA, five ſubulate filaments, placed in the tube of the corolla, and topped with double roundiſh antheræ.—PISTILLUM, a roundiſh germen, with a very ſhort ſtyle and blunt ſtigma.—PERICARPIUM, a large round berry, containing ten cells, in four or five of which are depoſited a compreſſed hard ſeed.

The ſpecies are,

[1]CHRYSOPHYLLUM, *Cainito.*

*Gold-coloured leaved Star-apple-tree.*] This ſpecies in its native country riſes to thirty or forty feet in height, furniſhed with many ſlender declining branches, on which grow oval ſtriated leaves, whoſe under ſide is downy, and of a gold colour; the flowers are produced in oblong bunches from the extremity of the branches, and are ſucceeded by a large berry.

[2]CHRYSOPHYLLUM, *Glabrum.*

*Mexican Medlar, or Sappatilla.*] The difference between this and the other ſpecies is, that it grows not near ſo large, the under part of the leaves are quite ſmooth, and the fruit is oval, about the ſize of a damſon; both ſpecies retain their leaves all the year.

*Propagation.*

The propagation of theſe trees are by ſeeds from their native country, which muſt be ſown in pots and plunged in a hot-bed, and when the plants have ariſen to three or four inches high, they ſhould be planted ſingly into ſmall pots, and replunged into the bark-bed, care being taken to ſhade and water them till they have got a freſh root, which they will ſoon do; after this they ſhould have a proper ſhare of air and water, according to the weather, and on the approach of winter, admitted into the ſtove, where they ſhould be treated as others of the like nature are.

COCCOLOBA, Sea-ſide Grape.

This genus of plants grow on the ſea ſhores in divers parts of the Weſt Indies, and are here admired for the largeneſs and ſhape of their leaves which are evergreen and very ornamental in the ſtove with other curious plants.

Claſs and order, *Octandria Trygynia.*

*Characters.*] CALIX, a monophyllous cup, divided into five parts.—COROLLA, none. STAMINA, conſiſts of eight ſubulate ſpreading filaments, which are ſhorter than the cup; the antheræ are roundiſh and double.—PISTILLUM, a three-cornered oval germen, with three ſhort, ſlender, ſpreading ſtyles, and ſimple ſtigmas.—PERICARPIUM, none, the cup containing the ſeed, which is an oval-pointed nut of one cell.

The ſpecies are,

[1]COCCOLOBA *Uvifera.*

*Shining-leaved Sea ſide Grape.*] The leaves are round, thick, and heart-ſhaped, about ſix or ſeven inches diameter; it grows on the ſea ſhores in moſt of the Weſt Indian iſlands.

[2]COCCOLOBA *Rubeſcent.*

*Downy-leaved Sea ſide Grape.*] With orbicular hairy leaves, about eight inches long, and three or four broad; it is a native of New Spain.

[3]COCCOLOBA *Excoriata.*

*Mountain Grape.*] With light-green, oval, heart ſhaped leaves, whoſe foot-ſtalks are joined to the under part; it grows in Campeachy.

[4]COCCOLOBA *Tenuifolia.*

*Small-fruited, Sea-ſide Grape.*] With oval membranaceous leaves of a light-green, about ſix inches long and three broad; it is a native of Jamaica.

[5]COCCOLOBA *Punctata.*

*Veined-leaved Sea-ſide Grape.*] With lanceolate oval leaves, three or four inches long, and indented at their foot-ſtalks; it is a native of New Spain.

All the ſpecies are of the ſhrubby kind, inclinable to be woody; they riſe ſix or ſeven feet high, and bear grape-like bunches; the fruit of ſome of the ſpecies are eaten in the Weſt Indies, but they produce none here.

CORDIA, Sebeſten.

It conſiſts of four or five ſpecies, one of which is worthy of notice.

Claſs and order, *Pentandria Monogynia.*]

*Characters.*] CALIX, a modophyllous tubulated cup, dentated at the top ——COROLLA, monopotalous, and funnel-ſhaped. ——STAMINA, five ſubulate filaments, with oblong antheræ.——PISTILLUM, a roundiſh-pointed germen, with a ſingle ſtyle the length of the ſtamina, and divided at top into two parts, each of which terminate with a blunt ſtigma.—PERICARPIUM, a globoſe-pointed drupe, faſtened to the cup.——

SEMINA,

SEMINA, a furrowed nut, containing four cells.

The *Cordia Sebeſten* riſes eight or nine feet high, with divers ſtems of the ſhrub kind, which, toward the upper parts, are furniſhed with rough ovato-oblong leaves of a deep green colour, and placed alternately on ſhort foot-ſtalks; the flowers are produced at the extremities of the branches in large cluſters on branching foot-ſtalks, each ſuſtaining one, two, or three flowers, of a rich ſcarlet colour; but they produce no ſeed in this country.

*Propagation.*

As this plant is a native of the Weſt Indies, the ſeeds muſt be procured from thence, as by ſeeds all the ſpecies are propagated; theſe obtained ſhould be ſown in pots, and plunged into a hot-bed, and about two months after, the plants ariſing will be fit to tranſplant ſingly, and again plunged; afterward they muſt be removed into the ſtove, where they ſhould conſtantly be kept.

CROTOLARIA.

We have no Engliſh name for this genus, which conſiſts of ſeveral ſpecies, which are all natives of foreign parts; but as the flowers of moſt of them have no great beauty, we ſhall only notice one ſpecie which deſerves obſervation, this is *Crotolaria Laburnifolia.*

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, a large cup divided into three parts.——COROLLA, is papilionaceous, conſiſting of a large, pointed, heart-ſhaped ſtandard, two ovate wings, ſhorter by half than the ſtandard, and an acuminated keel the length of the wings.—STAMINA, ten diadelphous filaments riſing upwards, crowned by ſimple antheræ. PISTILLUM, an oblong, reflexed, hairy germen, a ſimple ſtyle, riſing upwards, and an obtuſe ſtigma.—— PERICARPIUM, a ſhort, turgid, bivalvular pod, containing one or more roundiſh kidney-ſhaped ſeeds.

*Crotularia Liburnifolia*, riſes with a woody ſtem branching upwards, and furniſhed with oval pointed leaves about two inches long and one broad, of a light green, and are trifoliate; the flowers are produced at the ends of the branches in ſpikes, and are of a beautiful yellow colour; they blow the beſt part of the ſummer, and are ſucceeded by the pods and ſeeds; this plant being a native of India, requires a ſtove for its protection, though it will endure the open air in the warm ſummer months: it is propagated either by ſeeds or cuttings in the ſpring, but muſt be aſſiſted by a hot-bed.

D.

[3]DAPHNE *Cneorum.—Add,*

Daphne with ſhort woody ſtalks, of about nine or ten inches height, and furniſhed irregularly with ſmall lanceolate leaves of a dark green; the flowers are produced in cluſters along the extremities of the branches, and are of a purple colour; the ſcent of them is very agreeable, and as a farther recommendation they blow early in the ſpring when other flowers are ſcarce.

[4]DAPHNE *Indica.*

Daphne with a whitiſh woody ſtem, ſeldom growing above two feet high, with lateral upright branches, which are garniſhed with dark evergreen leaves, about an inch and a half long, and an inch broad, theſe are placed oppoſite to each other, they are ſmooth and of an oblong oval form; the flowers come out as the other ſorts, and are of a duſky colour.

The third ſort muſt be raiſed from ſeeds; they thrive beſt where they are ſown, as they rarely ſucceed by removing, and as they make an elegant pot flower, it would be eligible to ſow ſome ſeeds in ſmall pots, when they may at any time be ſhifted with balls ſo as not to miſcarry.

The fourth ſort is too tender to bear the open ground, it ſhould therefore be planted in a conſervatory, where it will thrive beſt; this plant is rather of ſtubborn growth, it is raiſed from ſeeds from abroad, which ſhould have a hot-bed to vegetate them.

DECIDUOUS PLANTS.

Such as caſt their leaves in winter, and is applicable to trees, ſhrubs, and herbaceous vegetables; and each of which tribes comprehend numerous Deciduous Plants; moſt of our valuable foreſt and fruit-trees are of the Deciduous kind; likewiſe the greater number of our moſt beautiful flowering ſhrubs that adorn the ſhrubberies are Deciduous; as are alſo a very great ſhare of the flowery perennials, both bulbous and fibrous-rooted kinds.

DIOSPYROS, Date Plum.

This genus are very ornamental plants for the ſhrubbery; the leaves being of a fine

green make a good contraſt with thoſe of other trees whoſe ſhape and tints are different.

Claſs and order, *Polygamia Dioecia.*

*Characters.*] *Hermaphrodite*, CALIX, a large, monophyllous, permanent, obtuſe cup, divided into four parts.—COROLLA, one large pitcher-ſhaped petal, divided into four acute ſpreading angles.—STAMINA, eight ſhort, ſetaceous filaments, firmly joined to the receptacle with oblong antheræ, which are deſtitute of farina.—PISTILLUM, a roundiſh germen, a ſingle, quadrifid, permanent ſtyle, longer than the ſtamina, and an obtuſe bifid ſtigma.—PERICARPIUM, a large globular berry of eight cells placed on the large patent cup.—SEMINA, the ſeeds are ſingle, roundiſh, compreſſed, and very hard.

*Male Flowers in diſtinct Plants.*

CALIX, a ſmall, erect, acute, monophyllous cup.——COROLLA, a three-cornered, pitcher-ſhaped, leatherey petal, cut into four roundiſh, revolute ſegments.—STAMINA, are eight ſhort filaments, inſerted in the receptacle, having long, acute, twin antheræ.

The ſpecies are,

[1]DIOSPYROS *Lotus.*

*Indian Date-Plum.*] Dioſpyros with an upright ſtem, and grows to the height of twenty feet; the branches are covered with a ſmooth whitiſh bark, the buds on the younger ſhoots begin to ſwell ſoon after the leaves are ſhed; the leaves are of a bright green, their figure is oblong, ending in a point, and are placed alternately on the branches, continuing green till they fall off in autumn; the flowers have no great beauty, they are of a rediſh colour, and are ſucceeded by large black berries, which are eatable like the medlar when in a ſtate of decay.

[2]DIOSPYROS *Virginiana.*

*Piſhamin-Plum.*] Dioſpyros with whitiſh ſmooth branches, growing in an irregular manner to the height of twelve or fourteen feet; the leaves are of a fine ſhining green, and five or ſix in length; at the time of their ſhedding, which is early in autumn, they turn to a purpliſh red, the flowers are like thoſe of the other ſpecies, and are ſucceeded by fruit, which are alſo eatable.

*Propagation.*

They are both raiſed from ſeeds, which need not the aid of a hot-bed, though they would come up more certain and quicker with one: in ſuch caſe they ſhould be ſown in pots, and when inured to the open air by degrees, ſhould remain undiſturbed until autumn, or rather till the ſpring, when they may be tranſplanted into a warm part of the nurſery, there to remain till they are arrived to a ſize fitting for the plantation they are deſigned for.

F.

[4]FRAXINUS *Integrifolia.*—*Add,*

*Entire-leaved Aſh.*] Hath oval-pointed entire leaves, grows to thirty feet; but as it has been diſcovered but a few years in Yorkſhire, and not flowered, botaniſts have not yet determined whether it is a diſtinct ſpecies, or only an accidental variety of the common aſh; though it certainly claims a ſpecific title, as all the other ſpecies are furniſhed with winged leaves.

G.

GORTERIA.

Conſiſts of ſhrubby plants, with naked branching flowers and downy ſeeds.

Claſs and order, *Syngeneſia Polygamia Fruſtanea.*

*Characters.*] CALIX, the common cup is monophyllous, and formed of prickly ſcales placed imbricatum.—COROLLA, is radiated and compound; the hermaphrodite florets fill the diſc, which are radiated with a few females.——STAMINA, five ſhort filaments, with cylindric antheræ.—PISTILLUM, a villoſe germen, ſlender ſtyle, and a bifid ſtigma.——PERICARPIUM, the calix which remains, the ſame containing ſolitary roundiſh ſeeds, crowned with down.

The ſpecies are.

[1]GORTERIA *Ringens.*

This is a low-growing plant, whoſe woody branches ſpread on the ground, and furniſhed with winged lanceolate leaves, parted into three or five parts at their extremities; the flowers which proceed from the branches are radiated, of a fine deep yellow colour, and appear in May.

[2]GORTERIA *Fruticoſa.*

Gorteria with a ſhrubby ſtalk, which riſes about three feet high, furniſhed with ſlender branches, on which are placed oblong indented leaves, armed at the edges with weak ſpines; their under-part are woolly, but ſmooth and green on the upper ſurface; the branches bear the flowers at their extremities, which are of a golden colour, and blow in June.

There are two or three other ſpecies, which are ſcarce worth mentioning.

They are propagated by cuttings in the ſummer months, being covered with glaſſes, and muſt be ſheltered in a green-houſe in winter.

GUILANDINA, *Bonduc*, or Nickar-tree.

There are ſeveral ſpecies of Guilandina, but the kind we ſhall mention here is hardy, and will endure our ſevereſt winters, the others being natives of the hotteſt climates.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, a monophyllous bell-ſhaped cup, cut at the brim into five parts.—COROLLA, five ſpear-ſhaped, concave, ſeſſile petals.——STAMINA, ten awl-ſhaped erect filaments, inſerted in the cup.—PISTILLUM, an oblong germen, with a ſlender ſtyle, and ſimple ſtigma.—PERICARPIUM, A rhomboidal, ſwelling, compreſſed, unilocular pod, having a convex future on the upper-ſide, containing one cell, and divided into many partitions by tranſverſe valves, in each of which are lodged a hard, roundiſh, and compreſſed ſeed.

The hardy ſpecies is,

GUILANL A *Dioica.*

*Canada Bonduc or Nickar-tree.*] The Bonduc riſes with a ſtem, which is firm and erect, to the height of fifteen or twenty feet, from which iſſues ſeveral branches, having a ſmooth, bluiſh, aſh-coloured bark; the leaves are bipinnate, of a dark-green, and the folioles are large, ſmooth, entire, and ranged alternately on the midril; the flowers are dioecious, there being male and female on different plants; they appear in July or Auguſt, but produce no ſeeds here.

*Propagation.*

This ſpecies is encreaſed by ſeeds procured from Canada and ſown in the ſpring, by layers in autumn, ſlitting them at a joint, or by the roots being cut and turned up in winter.

H.

HALESIA.

Conſiſts of two ſpecies, both of which are deciduous, ornamental, hardy ſhrubs, fitting to intermix with others in ſhrubbery plantations.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX, a ſmall, permanent, monophyllous cup, divided at the edge into four parts.—COROLLA, is ventricoſe, bell-ſhaped, and monopetalous, with the mouth cut into four obtuſe ſpreading parts.—STAMINA, are twelve ſubulate, upright, filaments, topped with oblong blunt antheræ.—PISTILLUM, an oblong germen, laying in the bottom of the cup; the ſtyle is ſlender, and crowned with ſingle ſtigma.—PERICARPIUM, an oblong corticated nut, with four membranaceous angles, and containing two cells, in each of which are depoſited a ſingle ſeed.

The ſpecies are;

¹HALESIA *Tetraptera.*

*Quadrangular-fruited Haleſia.*] This ſpecies frequently produces two or three ſtems from one root, which riſe to fifteen feet high, or upwards; the branches which ſpring from the principal ſtems are furniſhed with lanceolate oval leaves, jagged on their edges; the flowers which are of a white colour are produced in cluſters on the ſide of the branches, and the fruit is four-cornered.

²HALESIA *Diptera.*

*Two-angled Haleſia.*] Hath the ſtems like the firſt ſpecies; the leaves are oval, and their foot-ſtalks ſmooth; the fruit has two edges, which are winged.

This genus is propagated by ſeeds or layers; the ſeeds ſhould be ſown in the ſpring on a hot-bed, and treated in the ſame manner as many other Carolina plants are of the ſame nature. They may alſo be raiſed by laying; this may be done in autumn, by the laſt ſummer's ſhoots being brought down, firſt notching them in a joint, and the autumn following they will be fit to be taken off, and tranſplanted into the nurſery, where they may remain till arrived to a proper ſize to tranſplant for good.

L.

LAWSONIA.

Conſiſts of two ſpecies of tree-like plants, producing bunches of octandrious flowers.

Claſs and order, *Octandria Monogynia.*

*Characters.*] CALIX, a ſmall quadrifid permanent cup.—COROLLA, four oval ſpear-ſhaped petals, which are flat and ſpreading.—STAMINA, eight ſlender filaments of the length of the corolla.——PISTILLUM, is a roundiſh germen, with a ſingle perſiſtent ſtyle, crowned with a capitated ſtigma.—PERICARPIUM, a globular capſule ending in a point, containing four cells, in which are many angulated pointed ſeeds.

The ſpecies are,

¹LAWSONIA

[1]LAWSONIA *Inermis.*

*Egyptian broad-leaved Lawſonia.*] This riſes with a ſhrubby ſtalk, eight or nine feet high, the branches are ſlender, and are produced oppoſite to each other; the bark is of a yellowiſh colour, and they are furniſhed with ſmall-pointed leaves of a pale green; the flowers come out at the end of the branches in looſe bunches of a greyiſh colour, which are ſucceeded by capſules and ſeeds.

[2]LAWSONIA *Spinoſa.*

*Malabarian thorney Lawſonia.*] Is a tree which grows to the height of ſixteen or eighteen feet; the bark is of a light grey colour, the branches are produced as in the former ſpecies, and armed with ſtrong ſpines; the leaves are irregularly ſituated along the branches; they are of an oval-oblong figure, and of a light green, the flowers are produced from the ſides of the branches in looſe bunches, and are of a light-yellow colour; theſe are ſuccceeded by capſules of four cells, which contain the ſeeds.

Both ſpecies are propagated by ſowing the ſeeds in the ſpring on a hot-bed; and when the plants are up, and got to about three or four inches high, they ſhould be tranſplanted ſingly into ſmall pots, and replunged, obſerving to ſhade them till they have taken freſh root; they will bear the open air during the hot months in ſummer, and may be placed in the cooleſt part of the ſtove in winter, minding to give them but little water.

LEONURUS, Lion's-tail.

This conſiſts of herbaceous perennial plants, the flowers of which are of the labiated kind, and produced in whorls; there is one beautiful ſpecies which is cultivated in our gardens.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX, a monophyllous, tubulous, pentangular cup, which is permanent, and indented in five parts at the top.—COROLLA, a ringent petal, the tube is narrow, the limb gaping, and the chaps long; the upper-lip is ſemicylindrical, long, concave, gibbous, rounded at the top, hairy, and entire; the lower-lip is reflexed, and divided into three ſpear-ſhaped ſegments, which are nearly equal.——STAMINA, four filaments concealed under the upper-lip, of which two are ſhorter than the others; theſe are crowned with long compreſſed, bifid antheræ.——PISTILLUM, four germens, a filiforme ſtyle, the length and ſituation of the ſtamina, with a bifid acute ſtigma.—PERICARPIUM, none; the ſeeds are lodged in the cup.—SEMINA, four oblong ſeeds, convex on one ſide, and angular on the other.

The ſpecie is,

LEONORUS *Indicus.*

*Scarlet Lion's-tail.*] The root of this is perennial, from which ariſes ſeveral annual ſquare ſtalks, near a yard in height; theſe are garniſhed with ſpear-ſhaped ſerrated leaves, which grow oppoſite to each other at the joints; the flowers are of a rich ſcarlet, they appear in June or July, and frequently continue blowing the remainder of the ſummer.

This plant is propagated by dividing the roots in autumn; they grow beſt in a moiſt ſoil, and a ſhady ſituation, but not under the drip of trees; they may alſo be raiſed from ſeeds ſown either in autumn or ſpring.

LEPIDIUM. Garden Creſs.

Conſiſts of hardy herbaceous annuals of great eſtimation as ſmall-ſallad herbs; they riſing with many ſmall multifid leaves near the ground; and when they ſhoot to ſtalk, riſe a foot or more high, terminated by many ſmall, tetrapetalous, cruciform flowers, ſucceeded by ſmall ovaliſh ſeeds.

Claſs and order, *Tetradynamia Siliculoſa.*

*Characters.*] CALIX, a four-leaved deciduous cup.——COROLLA, four ſmall, oval, cruciform petals.—STAMINA, four long and two ſhort filaments, and ſimple antheræ.—PISTILLUM, a heart-ſhaped germen, ſimple ſtyle and obtuſe ſtigma.—PERICARPIUM, a nearly heart-ſhaped, compreſſed, bilocular pod, having very ſmall, oval, pointed ſeeds.

There is only one ſpecies of Garden Creſs, comprehending three varieties, all excellent ſallad herbs.

LEPIDIUM *Stativum.*

*Cultivated or Common Garden Creſs.*] Riſes with ſmall oblong leaves near the ground, multifid or cut into many parts; and erect ſtalks a foot or two high, terminated by many ſmall flowers in ſummer, ſucceeded by numerous ſmall red ſeeds, ripening in June, July, &c.

*Varieties.*] Common ſmall multifid-leaved Creſs, having the leaves finely divided.—Broad-leaved Creſs, having the leaves much broader than the former, and leſs divided.—Curled-leaved Creſs.

All the varieties are proper to cultivate as ſmall-ſallad herbs, being of a warm or hot biting reliſh, are excellent to mix with larger ſallading, ſuch as lettuce, endive, &c. See SALLAD HERBS and SMALL SALLADING.

They are all propagated by ſeed ſowed at many different times of the year, in order to continue a conſtant ſucceſſion of young plants for uſe, for theſe herbs ſhould always be cut for ſallading when they are only a few days old; otherwiſe they will be too hot and ſtrong taſted.

Therefore when a conſtant ſupply of thoſe ſallad herbs are required, they ſhould be ſowed every week all ſpring, ſummer, and autumn, and once every ten or twelve days in winter.

They ſhould be ſowed on warm borders early in ſpring; but as the warm weather advances, ſow them in any open ſituation; but in ſummer ſhould be ſowed in ſomewhat ſhady borders, and in winter ſowed in garden-frames, or under hand-glaſſes, and in ſevere weather are ſowed in hot-beds.

And as to the method of ſowing the ſeed, ſhould be ſowed very thick, either in ſhallow drills and covered a quarter of an inch deep, or all over the ſurface, and lightly raked in. See SMALL SALLADING.

LIMODORUM, Baſtard Hellebore.

An herbaceous exotic, very ornamental in the ſtove, containing only one ſpecies.

Claſs and order, *Gynandria Diandria.*

*Characters.*] CALIX, a ſheath from which the flower iſſues.—COROLLA, five oval oblong petals, the two upper ones connivent, and a monophyllous concave nectarium the length of the petals.—STAMINA, two, the filaments are in an oblong body, and riſing upwards, theſe are topped with ovate twin antheræ.——PISTILLUM, a columnar germen the length of the corolla, and placed below the flower, the ſtyle is ſlender, and growing from the body of the filaments, is crowned with a funnel-ſhaped ſtigma.—PERICARPIUM, a columnar capſule, with three valves, and one cell opening at the angles, containing many ſcobiform ſeeds.

The ſpecie is,

LIMODORUM *Tuberoſum.*

*Baſtard Hellebore* ] The root is of the bulbous kind, from whence ariſes three or four leaves, each narrowed at the baſe, and ending in a point, theſe are plaited; they are of a dark-green colour, and are nine or ten inches long, and one wide in the middle; the flower-ſtalk ariſes from the root to about eighteen inches high, this is ſmooth and of a brown purple colour; on the extremity of which the flowers are placed in a ſpike, about five or ſix in number, and inclining all one way; they are of a purpliſh-red colour, and are ſucceeded by a three-cornered columnar germen, which contain the ſeeds.

This plant ſhould be always kept in the ſtove; it is encreaſed by off-ſets, which ariſe from the roots; theſe may be taken off in autumn or ſpring, and planted ſingly into ſmall pots, and immediately plunged into the bark-bed.

M.

MIMULUS, Canada perfoliate Fox glove.

This genus comprehends one beautiful perennial ſpecies.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX, an oblong, priſmatic, five-cornered, permanent cup, indented in five patrs at top.—COROLLA, one ringent petal; the limb is bilabiated, the upper-lip is erect, bifid, rounded, and reflexed on the ſides; the lower-lip is broad, and cut into three roundiſh ſegments, the middle one being the ſmalleſt; the palate is convex and bifid.—STAMINA, four filiforme filaments, two being ſhorter than the others, with bifid kidney-ſhaped antheræ.—PISTILLUM, a conical germen, the ſtyle ſlender, and an oval bifid, compreſſed ſtigma.—PERICARPIUM, an oval bilocular capſule, containing many ſmall ſeeds.

The ſpecie is,

MIMULUS *Ringens.*

*Canada prefoliate Fox-glove.*] The ſtalks of this plant are ſquare-jointed, and riſe upright about two feet; the leaves ſurround the ſtalk at each joint, they grow oppoſite, and are oblong, ſmooth, and pointed; the flowers are produced ſingly from the joints at the baſe of the leaves, and are large and of a beautiful blue colour; they appear in July, and are ſucceeded by capſules filled with ſeeds.

This ſpecies is propagated either by parting the roots or by ſeeds; the beſt time for either is autumn.

MORINA.

A hardy perennial plant, with upright deciduous

ciduous ſtalks, and prickly leaves, producing labiated flowers.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, a double cup, each monophyllous, permanent, and tubular, cut at the top into two ſegments.—COROLLA, a bilabiated petal, with a very long tube, ſlender near the baſe, but wide and large at the top, and a little incurved, the limb is plane and obtuſe, the upper-lip is ſmall and ſemibifid; the lower-lip is cut into three obtuſe ſegments, the middle one being the longeſt. —STAMINA, two ſetaceous filaments, ſhorter than the limb, with erect, heart-ſhaped antheræ. — PISTILLUM, a globoſe germen, placed under the receptacle of the flower, a ſlender ſtyle, and a capitated, peltated, inflexed ſtigma.—PERICARPIUM, none; the ſeed which is ſingle and roundiſh ſtands in its own permanent cup, and is crowned with the empalement of the flower.

The ſpecie is,

MORINA *Perſica.*

*Oriental Morina.*] The root of this plant is large, taper, oblong; ſtrikes deep in the ground, and is furniſhed with many fibres; the radical leaves are very large and oblong, divided at their edges, armed with prickles, and of a bright green colour; the ſtalk is ſmooth, upright, and ſtrong, riſing to about a yard high, and furniſhed with leſſer leaves of the ſame form as the radical; the flowers are produced at the ſides and heads of the ſtalks in ſmall heads; they appear in July, are of different colours; theſe are ſucceeded by the ſeeds.

The varieties of this ſpecie are the white, —purple,—pale-red,—deep-red.

This plant is propagated by ſowing the ſeeds when ripe; and as the roots are of the tap kind, the ſowing ſhould be where the plants are intended to flower; they will come up the ſucceeding ſummer, and the year following will exhibit their bloſſoms, which they will continue to do for ſeveral years following, if not diſturbed.

## N.

### NOLANA.

An herbaceous trailing plant, much admired for the beauty of its pentandrious flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a monophyllous cup, turbinated, divided into five parts, and five angles. — COROLLA, monopetalous, bell-ſhaped, plicated, and ſpreading, and double the ſize of the cup.—STAMINA, five erect awl-ſhaped filaments, ſhorter than the corolla, and topped with ſagittate antheræ—PISTILLUM, five roundiſh germens; the ſtyle is cylindric and ſtrait, with a capitated ſtigma. ——PERICARPIUM, none; but the ſeeds which are five, roundiſh, and of a ſucculent bark, are lodged in the inner baſe of a naked receptacle.

We know but of one ſpecies belonging to this genus.

NOLANA *Proſtrata.*

The root is fibrous, from which iſſues a few trailing ſtalks furniſhed with deltoid leaves, about the length and breadth of an inch, of a dull-green colour; the flowers come out from the ſides of the branches; they are of a fine blue colour, penciled with dark ſtreaks, half way from the center to the limb, and the antheræ are of a light blue colour, which adds much to the beauty of the flower.

The Nolana is annual, it is raiſed by ſeeds ſown on a hot-bed in the ſpring; the plants afterwards may by degrees be hardened to the open air, in which it will blow beſt part of the ſummer.

### NYSSA, the Tupelo tree.

An ornamental tree, for the plantations, particularly where it is warm and moiſt, it is a native of North America.

Claſs and order, *Polygamia Dioecia.*

*Characters.*] *Male.*—CALIX, a peranthium, divided into five ſpreading ſegments.—COROLLA, none.—STAMINA, ten awl-ſhaped filaments, ſhorter than the cup, with didymous antheræ —*Hermaphrodite.*—CALIX and COROLLA, the ſame as the male.--STAMINA, five ſubulate filaments, with ſingle antheræ —PISTILLUM, an oval germen, ſituated under the receptacle, a ſubulated incurved ſtyle, longer than the ſtamina, and an acute ſtigma.—— PERICARPIUM, an oval drupe of one cell, containing an oval acute nut, marked with longitudinal furrows, angular and irregular.

The ſpecie is,

NYSSA *Aquatica.*

*The Virginian Tupelo-tree.*] This tree riſes with a regular trunk near twenty feet high, on the top of which ſeveral branches grow; the leaves are ſpear-ſhaped, ſoft, of a thickiſh conſiſtence, and ending in acute points; they are very ornamental, of a fine light-green colour, grow alternately on pretty long foot-

foot-ſtalks, and retain their colour late in autumn.

*Varieties.*] Entire-leaved Tupelo,—ſerrated-leaved, or multiflorous Tupelo.

Their propagation is from ſeeds, which muſt be procured from America, but as the ſeeds come not up the firſt year they may be buried in pots of mould, and plunged where the ground is naturally moiſt, ſcreening them from the froſt in winter; the ſpring following let them be plunged in a hot-bed, which will ſoon vegetate the ſeeds, if they are good, and the plants will quickly appear, after which allow them a tolerable ſhare of air, and harden them to it by degrees: the autumn following they ſhould be ſheltered in a green-houſe, or glaſs-frame during the winter; the third ſpring they ſhould be ſeparated and planted ſingly into ſmall pots, and again plunged, &c. as before; ſhelter them again another winter, and in the ſpring following they may be planted where they are intended to remain, which ſhould be in a well-ſheltered and moiſt ſituation.

## O.

OSYRIS, Poet's Caſſia.

A plant of the ſhrubby kind; it grows naturally in the ſouth of France, Italy, and Spain, upon rocky, ſandy, or ſtony places.

Claſs and order, *Dioecia Triandria.*

*Characters.*] *Male.*—CALIX, a monophyllous turbinated cup, cut into three equal, oval, acute ſegments.—COROLLA, none.—STAMINA, three very ſhort filaments, with ſmall roundiſh antheræ.—*Female*, CALIX and COROLLA, as the male.—PISTILLUM, a top-ſhaped germen, ſituated below the cup, with a ſtyle the length of the ſtamina, and a ſtigma divided into three ſpreading parts.—PERICARPIUM, a globular umbilicated berry of one cell, containing the ſeed, which is a globular *oſſiculum* filling the pericarpium.

The ſpecie is,

OSYRIS *Alba.*

*Poet's Caſſia.*] This ſpecies riſes with a ſhrubby branching ſtalk to about two feet high; the leaves which are of a bright green are long, narrow, and pointed; the flowers appear in June, they are ſmall and of a yellowiſh-green colour, and ſucceeded by middle-ſized roundiſh berries, which when ripe are of a bright red colour.

The propagation of this plant is by ſowing the berries on the rocky, ſandy, or gravelly ſide of a hill, in the places where they are intended to remain, for as the beauty of this plant conſiſts in its fruit, it will not ſo well ſucceed by raiſing them in the cultivated part of the garden, the berries always dropping off before they are come to maturity; the berries ſhould be ſown in autumn when ripe, and as they often remain in the ground two or three years before they vegetate, the places where they are ſown ſhould therefore be marked and all weeds kept clear from them.

## P.

PANAX, Ginſeng.

A genus of herbaceous umbeliferous plants, the root of which is much celebrated among the Chineſe and Tartars, who affirm, it is a ſovereign remedy for all kinds of diſorders; its excellency conſiſts in being reſtorative, and a great ſtrengthener to the ſtomach.

Claſs and order, *Polygamia Dioecia.*

*Characters.*] *Hermaphrodite.*——CALIX, a ſimple, equal, and cloſe umbel; the involucrum is compoſed of ſeveral awl-ſhaped, ſmall, permanent leaves; the proper cup is ſmall and permanent.—COROLLA, the general flower is uniform; the florets have each five equal, oblong, recurved petals.—STAMINA, five very ſhort filaments, with ſingle antheræ—PISTILLUM, a roundiſh germen placed below the flower, with two ſmall upright ſtyles, topped with ſimple antheræ.——PERICARPIUM, a heart-ſhaped umbilicated berry with two cells, each containing a ſingle heart-ſhaped ſeed.—*Male.*—CALIX, a ſingle and round umbel; the involucrum is compoſed of ſeveral ſpear-ſhaped folioles, which are ſeſſile, and the peranthium is turbinated, whole, and coloured.—COROLLA, is five oblong, blunt, narrow, reflexed petals, ſitting on the cup.—STAMINA, five filiforme filaments, inſerted in the cup, having ſimple antheræ.

Of this genus there are two ſpecies.

PANAX *Quinqueſolium.*

*Or five-leaved Ginſeng.*] This plant has a fleſhy taper root, browniſh without, and yellow within, about a third of an inch in diameter on the upper-part, and of an agreeable bitter flavour; from this ariſes the ſtalk, to the height of about a foot, of a reddiſh colour, dividing at the top into three or four bunches, which ſupport the leaves; theſe are quinate,

quinate, of a pale-green colour, the folioles of which are lanceolate, hairy, and ſerrated; the flowers come out in umbels; they appear in June, and are ſucceeded by the ſeeds, which ar[illegible]e in Auguſt.

[2]PANAX *Trifolium.*

*Three-leaved Ginſeng.*] Hath a ſmall, taper, fleſhy root, with trifoliate leaves, which are cut deeply on their edges; the flowers are produced in ſmall bunches on foot-ſtalks; they are ſmall and greeniſh.

POLYGALA, Milkwort.

This genus conſiſts of herbaceous, perennial plants, the ſtalks riſing from eight inches to eighteen, according to the different ſpecies, they are furniſhed with ſpear-ſhaped leaves and flowers growing in ſpikes.

Claſs and order, *Diadelphia Octandria.*

*Characters.*] CALIX, a ſmall cup, compoſed of three oval, acute, permanent leaves, two of which are below the corolla, and the other above it.—COROLLA, papilionaceous; the wings are large, oval, plane, and placed beyond the other parts of the corolla; the vexillum is ſhort, tubular, and a little reflexed, and bifid at top; the carina is concave, compreſſed, and ventricoſe towards the apex.—STAMINA, diadelphous filaments, with eight ſimple antheræ.——PISTILLUM, an oblong germen, a ſimple erect ſtyle, and a thickiſh bifid ſtigma.—PERICARPIUM, a turbinated, heart-ſhaped, compreſſed capſule, compoſed of two valves, having two cells, containing each a ſingle oval ſeed.

The ſpecies are,

[1]POLYGALA *Vulgaris.*

*Common Milkwort.*] This hath a root, which is long, ſlender, and white; the ſtalks are ſlender, herbaceous, growing on the ground, ſix or eight inches in length; the leaves are ſmooth, narrow, ſpear-ſhaped, pointed at the end, and of a bright-green colour, the flowers are produced from the ends of the ſtalks in creſted ſpikes; they appear in June, and the ſeeds ripen in Auguſt.

*Varieties.*] Blue,—red,—white violet-coloured,—ſtriped milk-wort,

[2]POLYGALA *Amara.*

*Bitter Milkwort.*] The radical leaves are large and oval, the ſtalks are herbaceous, erect, and ſix or eight inches high; the flowers are produced on the tops of the ſtalks in creſted ſpikes of different colours; but chiefly blue; they appear in June, and the ſeeds ripen in Auguſt. This plant is intolerably bitter to the taſte.

[3]POLYGALA *Microphylla.*

*Shrubby Portugal Milkwort.*] The ſtalks are ſmall, ligneous, of a green colour, growing about a foot high; the leaves which are placed alternately, are ſmall, oval, awl-ſhaped, narrow, and ſeſſile; the flowers are produced in ſhort ſpikes on the tops of the ſtalks in May and June; they are large, and often of two or three colours; the ſeeds ripen in Auguſt.

[4]POLYGALA *Chamæbuxus.*

*Dwarf Box Milkwort.*] The ſtalks are ſlender, ligneous, and branching, about a foot high, the leaves are numerous, ſpear-ſhaped, ſmooth, and of a bright-green colour; the flowers come out from the ſides of the ſtalks towards the upper-part; they are white without-ſide, with a mixture of purple and yellow within; they are very finely ſcented, and appear in May.

[5]POLYGALA *Senega.*

*Senega Milkwort, or Rattle-ſnakewort.*] Hath a thick, fleſhy, perennial root, which ſtrikes deeply into the ground, from which ariſe three or four ſtalks, about half a yard high; theſe are herbaceous, upright, and ſlender; the leaves are ſpear-ſhaped, broad, and grow alternately; the flowers are produced at the ends of the ſtalks in ſpikes, they are ſmall, of a white colour, appear in July, but ſeldom produce ſeeds in England.—The virtues of the root of this plant, when ſufficiently known, will be very great in medicine; it is allowed to be a powerful cleanſer of the blood, a fine diuretic, diaphoretic, and cathartic; it is uſed in hydropic caſes, pleuriſies, &c. but what makes it remarkable, is its being an infallible cure for the bite of a rattle-ſnake, if uſed in time, by reducing it to powder, rubbing the wound with it, and taking about thirty grains internally.

*Propagation.*

The firſt and ſecond ſorts are eaſily propagated by ſowing the ſeeds when ripe, and keeping the ground clear of weeds; the third and fourth ſorts are raiſed in the ſame manner, but require ſome protection from the froſts in winter: the fifth ſort is alſo raiſed from ſeeds procured from America; they ſhould be ſown in light, warm, ſandy ground, and in winter protected from the ſeverity of the weather.

[6]POPULUS

[6]POPULUS *Canadenſis.—Add,*

*Canadian Poplar.*] Riſes with a ſtrait trunk, regularly branching to a conſiderable height; the bark is whitiſh, the leaves are roundiſh, ending in an obtuſe point, and the border waved, and of a light-green colour.

[7]POPULUS *Græcæ.*

*Athenian Poplar.*] Riſes with a ſtrait whitiſh ſtem, growing ſix or ſeven feet in a year, furniſhed with branches, which are garniſhed with large cordate leaves, of a beautiful green colour: this Poplar has but of late years been introduced into England, and by the rapidity of its growth, and the beauty of its leaves, bids fair to be the fineſt plant of all the ſpecies.

This ſpecies is beſt propagated by graſting on the Lombardy; but as it out grows the ſtock, it ſhould therefore be graſted cloſe to the ground.

PROTEA. The Silver-tree.

A genus of green-houſe plants of the perennial, evergreen, woody kind, growing to the height of eight or ten feet, and ornamented with beautiful ſilvery leaves, very much like ſattin.

Claſs and order, *Tetandria Monogynia.*

*Characters.*] CALIX, a general imbricated perianthium, containing many florets, each having a monophyllous cup.—COROLLA, the general flower, which is uniform, conſiſts of many monopetalous florets, cut at the limb into four parts, which are ſmooth and ſpreading.—STAMINA, four filaments inſerted in the corolla, and incumbent antheræ.——PISTILLUM, a roundiſh germen, erect ſetaceous ſtyle, and obtuſe ſtigma.——PERICARPIUM, none; one ſeed to each floret lodged in its calix.

The ſpecies are,

[1]PROTEA *Argentea.*

*Cape Protea or Silver-tree.*] Hath a ſtrong upright, ſtalk, with a purpliſh bark; this divides into ſeveral erect branches, which are garniſhed with broad, lanceolate, ſilky-white, ſhining leaves, which continue all the year, rarely flowering in England.

[2]PROTEA *Conifera.*

*Cone-bearing Protea.*] Hath an upright ſtem, dividing into branches upwards, which are garniſhed with lanceolate, linear, entire leaves, of a ſhining ſilvery colour, the whole plant making a fine appearance.

Both ſorts are propagated by ſeeds procured from the Cape of Good Hope; theſe ſhould be ſown on a moderate hot-bed in the ſpring, and when the plants are up, ſhould be houſed in any airy glaſs-caſe, or the cooleſt part of the green-houſe; but by no means put them in the ſtove, which is certain death to them, as they cannot bear fire heat, requiring only to be ſheltered from froſt, &c.

S.

SARRACENIA, Side-ſaddle flower.

A genus much admired for the ſingularity of their leaves and flowers; they are perennial and herbaceous, the leaves are numerous, of a peculiar conſtruction, and the flowers are ſingle and polyandrious: it admits of two ſpecies.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, a double perianthium, the lower are compounded of three ſmall, oval, deciduous leaves, and the upper one of five large coloured leaves, which alſo fade away.—COROLLA, five oval inflexed petals covering the ſtamina with oval oblong claws.—STAMINA, a number of ſmall filaments, topped with ſimple antheræ.—PISTILLUM, a roundiſh germen, the ſtyle very ſhort and cylindric, topped with a cylpeated, peltated, quinquangular ſtigma, covering the ſtamina.—PERICARPIUM, a five-celled roundiſh germen, containing many roundiſh-pointed ſmall ſeeds.

The ſpecies are,

[1]SARRACENIA *Purpurea.*

*Purple Sarraſenia.*] Hath a fibrous root, ſtriking deep in the ground; the leaves are pitcher-ſhaped, of a firm ſubſtance, ariſing from a ſmall baſe, and widening by degrees to the neck in an upright poſition, ſo as to contain a quantity of water; from the root ariſes the flower ſtem; it grows to the height of half a yard, and is round, naked and upright; the flowers decorate the top of the ſtalks, and are ſingle, large, of a fine purple colour, and hang drooping; they appear in June, and ſometimes the ſeeds ripen in autumn.

[2]SARRACENIA *Flava.*

*Yellow Sarracenia.*] Hath a root like the former; the leaves are numerous, hollow, ſtanding on a ſlender baſe, wide at the top, and grow to the height of a yard; the ſtalks are naked, on the tops of which the flowers are produced, which grow ſingly, and of a yellow colour, and come out in June or July;

a va-

a variety of this ſpecies hath green flowers. Theſe plants are natives of moiſt boggy places in North America; their ſituation in England ſhould therefore be ſimilar; but ſevere froſts ſhould be guarded againſt for their protection; the readieſt way of procuring, (if not in England), is to have them from North America, as there is at preſent no mode of propagation here, yet diſcovered.

SOPHORA.

Conſiſts of a genus of perennial plants, whoſe leaves are winged, and the flowers produced in ſpikes.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, a ſhort monophyllous, bell-ſhaped cup, divided at the top into five oblique blunt ſegments.—COROLLA, papilionaceous and quinpetalous; the vexillum is oblong, broader at top, and reflexed on the ſides; the wings are two, oblong and appendiculated at their baſe; the carina is compoſed of two petals like the wings, with their lower edges joined together.—STAMINA, ten diſtinct awl-ſhaped filaments concealed in the carina, with very ſmall aſſurgent antheræ.—PISTILLUM, an oblong taper germen, the ſtyle the ſize and ſituation of the ſtamina, and an obtuſe ſtigma.——PERICARPIUM, a long, ſlender, unilocular pod, containing many roundiſh ſeeds.

There are two ſpecies of this genus, which are hardy.

[1]SOPHORA *Alopecuroides.*

*Oriental Sophora.*] Hath a creeping root, from which the ſtalks ariſe; they are upright, and three or four feet in height, the leaves are winged, compoſed of many ſmall, oblong, hairy folioles, ending with an odd one; the flowers come out in ſpikes from the ſides and ends of the ſtalks, and are of a pale blue colour, appearing in July.

[2]SOPHORA *Tinctoria.*

*Virginian Sophora.*] Hath a perennial root, from whence ariſe many weak procumbent ſtalks; the leaves are compoſed of three roundiſh ſmooth folioles, which join at the baſe, and grow on very ſhort foot-ſtalks; the flowers are produced in ſhort ſpikes in July; they are of a yellow colour, and ſometimes ſucceeded by ſeeds, which ripen in autumn. To theſe may be added two other ſpecies, which are perennial, of the ſhrub kind, but being tender, require a ſtove.

[3]SOPHORA *Mirophylla.*

*Small-leaved Otaheite Sophora.*] This hath been lately introduced into this kingdom; the whole plant is very elegant, the leaves are winged, the folioles, which are numerous, are roundiſh, about a quarter of an inch long, of a dark green colour.

[4]SOPHORA *Tomentoſa.*

*Silvery Ceylon Sophora.*] Hath a downy ſtalk, riſing ſix or ſeven feet high; the leaves are winged, conſiſting of five or ſix pair of folioles, which are roundiſh and woolly; the flowers grow in ſpikes, and are of a yellow colour; theſe are ſucceeded by woolly taper pods, which contain the ſeeds.

The firſt and ſecond ſorts are propagated by parting their roots in autumn or ſpring; they may alſo be raiſed by ſowing their ſeeds.—The third and fourth are propagated by ſowing their ſeeds on a hot-bed; the plants from thence ariſing, when fit, ſhould be potted and plunged into the bark-bed in the ſtove, where they ſhould be conſtantly kept.

STAPELIA, Swallow-wort.

Conſiſts of two ſpecies of ſucculent, perennial plants, which are deſtitute of leaves, producing from the ſides of the ſtalks; variegated pentandrious flowers of a ſingular appearance.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, monophyllous, ſmall, acute, divided into five parts, and perſiſtent.—COROLLA, monopetalous, large, flat, divided half way into five parts, and containing a ſtarry, five-pointed nectarium, with linear ſegments, whoſe lacerated points ſurround the parts of generation.—STAMINA, five plain, broad, erect filaments, with linear antheræ joined to the ſides of the filaments.—PISTILLUM, two oval plane germens, without a ſtyle, each having a blunt ſtigma.—PERICARPIUM, two oblong, ſubulate pods, with ſingle cells and valves, containing many imbricated compreſſed ſeeds, crowned with a pappoſe down.

The ſpecies are,

[1]STAPELIA *Maculata.*

*Spotted Stapelia or Fritillaria Craſſa Minor.*] Hath many ſucculent ſpreading branches, with ſeveral protuberancies on their ſides riſing about ſix inches; from the ſides of the branches are produced the flowers, which are ſingle, ſeldom ſhewing more than two at a time, which are continued in ſucceſſion, each conſiſts of a ſtellated petal, which ſpreads open, green on the outſide, but yellow within, and ſpotted with deep

purple; the centre is occupied by a coloured nectarium, which includes the parts of generation, when the flower is decayed; the germen are ſucceeded by two taper pods, which join at their baſe, and contain many ſeeds crowned with feathery down.

²STAPELIA *Hirſuta.*

*Hairy Stapelia or Frittillaria Craſſa Major.*] Hath upright ſucculent branches, which are angulated and indentured on the edges, and of a greeniſh-purple colour; from the ſides of the branches the flowers are produced; they are large, ſtellated, hairy, and variegated with purple ſtripes, which run acroſs the petal: both the ſpecies ſhew their flowers in the ſummer months, which are of ſo very fœtid a ſcent as to induce the fleſh-flies to lay their eggs thereon. Theſe plants ſhou'd be kept always in the ſtove on the flue or ſhelves, where they will blow every ſummer, obſerving to let them have but little water in winter. They are eaſily propagated by the branches being ſlipped off, and laying them by for a few days in the ſun to heal the wound, after which they may be put in pots with poor earth, not over moiſt, and plunged in the tan, where they will readily take root in any of the ſummer months.

## T.

TELEPHIUM, Orpine.

Conſiſts of a perennial plant, whoſe ſtalks are procumbent; the leaves ſmall, and oval, and the flowers produced in ſpikes.

Claſs and order, *Pentandria Trigynia.*

*Characters.*] CALIX, five oblong, blunt, concave, carinated, permanent leaves.—COROLLA, five oblong, obtuſe, erect petals, narrowed at the baſe.—STAMINA, five ſubulate filaments, with incumbent antheræ.—PISTILLUM, a three-ſided acute germen without a ſtyle, with three acute patent ſtigmas.—PERICARPIUM, a ſhort three-ſided capſules, formed of three valves and one cell, containing many roundiſh ſeeds.

The ſpecie is,

TELEPHIUM *Imperati.*

*Orpine of Imperatus, or Live-long.*] Hath a thick, hard, fibrous root, of a yellowiſh colour, the ſtalks which lie on the ground are numerous, round, ſlender, green, eight or ten inches long; the leaves are ſmall, oval, ſtiff, ſmooth, of a greyiſh colour, and grow alternately; the flowers are produced in ſhort, thick, reflexed ſpikes, and grow at the ends of the branches; their colour is white, appear in June or July, and the ſeeds are ripe in autumn. This plant is propagated by ſowing the ſeeds in autumn on a light and dry ſoil, where they are to remain; the ſucceeding ſpring the plants will be up, and the next year will bloom and ripen their ſeeds.

THEA. The Tea-tree.

An ever-green, woody, Chineſe plant, the dried prepared leaves of which are univerſally made uſe of; the flowers are polyandrious and roſaceous.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, a ſmall flat, perianthium, divided into ſix parts, the folioles of which are roundiſh, blunt, and perſiſtent.—COROLLA, ſix roundiſh, large, concave petals, which are equal.——STAMINA, many ſlender filaments, ſhorter than the corolla, with ſimple antheræ.—PISTILLUM, a three-cornered globoſe germen with an awl-ſhaped ſtyle, crowned with a tripple ſtigma,—PERICARPIUM, a trilocular capſule, joining in three round bodies, and opening at the top.—SEMINA, the ſeeds are ſingle, round and angulated at their backs.

There are ſuppoſed to be two diſtinct ſpecies, the leaves of which are imported in great quantities from China, and go by the denomination of green and bohea tea; but as it is not yet ſettled by botaniſts, whether the two ſorts are from one or diſtinct plants, we ſhall confine ourſelves to the ſort growing here in England.

THEA.

*The Tea-tree.*] Hath a fibrous root, from which riſes a ſtem covered with an aſh-coloured bark; the leaves are placed alternately on the branches; they are oval, obtuſely pointed, ſawed at their edges, are about two inches wide and four long, of a dark green colour; the flowers which come out from the ſides of the branches are roſaceous, and of a white colour; theſe are ſucceeded by a capſule with three cells, each containing a ſingle ſeed. The tea-tree is not ſo tender as many imagine, for it will not ſucceed well in the ſtove; there are ſome few planted in the natural ground, where they ſeem to thrive beſt; the ſituation ſhould be in a well ſheltered part of the garden, where it is not too moiſt, and in winter they ſhould be protected from ſevere weather; here they will thrive much better

better than keeping them in pots in the houſe, and will ſhew plenty of bloſſoms; they are propagated by layers.

V.

VACCINIUM, Whortle-berry, Bilberry, or Cranberry.

Comprehend a genus of dwarf ſhrubby plants, producing eatable fruit.

Claſs and order, *Octandria Monogynia.*

*Characters.*] CALIX, a very ſmall perianthium, ſituated above the germen.—COROLLA, a campanulated petal, divided at the brim into four revoluted ſegments.—STAMINA, eight ſimple filaments, with two horned antheræ, opening at the point, and furniſhed with two ſpreading ariſtæ on the outſide.—PISTILLUM, a germen ſituated below the cup, a ſingle ſtyle longer than the ſtamina, and an obtuſe ſtigma.—PERICARPIUM, a globular umbilicated berry, with four cells, containing a few ſmall ſeeds.

Of this genus are the following ſpecies.

[1]VACCINIUM *Myrtillis.*

*Bilberry or Black-whorts.*] Hath an angular, branching, ſhrubby ſtalks, growing to the height of about two feet; the leaves are oval, oblong, a little ſerrated, ſmooth, of a dark-green colour, and fall off in winter; the flowers come out ſingly from the ends and ſides of the branches, on foot-ſtalks of a greeniſh-white colour, appearing in April and May, which are ſucceeded by large eatable berries.

[2]VACCINIUM *Uliginoſum.*

*Great Bilberry.*] Hath a woody branching ſtalk, which riſes to about three feet; the leaves are thin, veined, oval, entire, and underneath whitiſh; the flowers grow ſingly on their ſeparate foot-ſtalks, are of a whitiſh-purple colour; they appear in April and May, and are ſucceeded by large berries which ripen in July.

[3]VACCINIUM *Album.*

*White Bilberry.*] Hath a ſtalk which riſes to about half a yard in height, is woody and branching; the leaves are entire, oval, and downy underneath, the flowers are produced from the ends and ſides of the branches in ſmall cluſters; they appear in May, and are ſucceeded by berries, when ripe they are of a white colour.

[4]VACCINIUM *Vites Idæa.*

*Red Whortle-berry*] Hath very ſlender branching ſtalks, growing about ſix inches high, the leaves are ever-green, of a firm conſiſtence, oval, and ſmooth, and maculated on their under-ſide; the flowers grow in cluſters from the ends of the branches; they are of a reddiſh colour, and appear in May, and are ſucceeded by red juicy berries, which when ripe are much eſteemed for tarts.

[5]VACCINIUM *Oxycoccos.*

*Cranberry.*] Hath ſlender procumbent ſtalks, the leaves are ſmall, oval, entire, and reflexed on their edges; the flowers grow on long ſlender foot-ſtalks at the tops of the branches, are of a re' colour; appear in May and June, and are ſucceeded by berries, well known for tarts.

[6]VACCINIUM *Hiſpidulum.*

*Marſh Virginian Whortle-berry*] Hath trailing ſtalks, which are ſlender, rough, and imbricated; the leaves which turn backward are oval and entire; the flowers are produced from the tops of the branches on ſlender foot-ſtalks; they appear in May, and are ſucceeded by very large red berries.

The four firſt ſorts grow naturally in cold, light, ſandy woods, heaths, &c. To propagate them the roots ſhould be taken up from the places where they grow ſpontaneouſly, reſerving a quantity of mould to them, and planting them in a ſimilar ſoil and ſituation; in ſuch places they will thrive and encreaſe. The two laſt ſpecies require a boggy undiſturbed marſhy ſoil, to which the plants muſt be removed from where they naturally grow. The berries of moſt of the ſorts are noted for making excellent tarts, &c.
